Infants were observed for local and systemic reactions following 283 of the injections. Local reactions ranging from mild to severe were observed following 55 of the injections (19 percent). Systemic reactions ranging from mild to moderate, according to the criteria used, followed 33 injections (11 percent). Local reactions occurred among 33 (23 percent) of the 147 who received aluminum phosphate adsorbed antigen and among 22 (16.2 percent) of 136 receiving aluminum hydroxide adsorbed antigen injections. Of the 30 systemic reactions, 12 followed the aluminum hydroxide, and 18 the aluminum phosphate antigen. The differences observed are not statistically significant.

Discussion

The data indicate that of the two antigens used, the aluminum phosphate adsorbed product is superior in combined diphtheria and pertussis neonatal immunization. The possibility that factors other than antigenicity could have influenced the results must be considered. Although losses from the study impose important limitations, the losses were equally divided according to the antigen used. Of 21 infants

Although higher titers were observed 1 month following inoculation in the group receiving the aluminum phosphate antigen, these infants also had higher titers in the preinoculation cord blood specimens (fig. 5). There were no differences in the antigens when response was based upon increase in titer.

Titration of diphtheria antitoxin 1 year after completion of the DTP injection can be compared with the levels observed at 1 month following the third injection in 54 infants from whom 1-month and 1-year postvaccination

specimens were obtained (fig. 6). Twenty-five of these infants had received the aluminum hydroxide and 29 the aluminum phosphate adsorbed antigen. Thirty infants maintained the same level of antitoxin units per ml., equally distributed between the two antigens. An increase at 1 year was noted in 17 of the 54 infants, including 6 of the 25 who had received aluminum hydroxide adsorbed antigen and 11 of the 29 receiving the aluminum phosphate antigen. The antitoxin level was lower at 1

year in 7 of the infants, 4 of whom had received aluminum hydroxide antigen and 3 aluminum phosphate antigen. No differences were observed in the ability of the two antigens to maintain antitoxin levels of 1.0, 0.1, or 0.01 units per ml. at 1 year following completion of immunization.

Combined Protection

Table 3 presents the combined results of pertussis agglutination and diphtheria antitoxin titration 1 month after the third inoculation. These data may be observed at any agglutination and antitoxin level for pertussis and diphtheria. Selecting as a criterion a titer of 1:160 or more for pertussis protection and at least 0.1 antitoxin unit per ml. (AU/ml.) for

num hydroxide adsorbed preparation. Better combined protection against diphtheria and pertussis followed inoculation with the aluminum phosphate adsorbed antigens.

No differences in local or systemic reactions following the two types of antigens were observed.

The data confirm the desirability of a fourth dose or booster dose at 1 year of age when inoculation is begun during the neonatal period.

Conference on Training

Sixty-five representatives of professional and educational groups will attend a national conference on public health training to be held in Washington, D. C., July 28-30, 1958, under the sponsorship of the Public Health Service.

Dr. Berwyn F. Mattison, executive secretary of the American Public Health Association, will be chairman of the meeting. Dr. Malcolm H. Merrill, director of the California Department of Public Health, will summarize conference conclusions.

The meeting will review responsibilities of local, State, and Federal agencies for the training of public health personnel. The Health Amendments Act of 1956 requires that a national conference be held to assist the Surgeon General of the Public Health Service in evaluating the public health traineeship program authorized by the act. The act also requires the Surgeon General to make an evaluation report to Congress by January 1, 1959.

The purpose of the traineeship program is to help alleviate the acute shortage of trained personnel in public health agencies. Under the act, the Public Health Service awards traineeships to individuals and makes training grants to schools offering graduate courses in public health. From August 1956 through April 1958, almost 1,000 persons received graduate training in public health through this program.

lost to the study before the third postvaccination specimen, 11 were in the aluminum phosphate group and 10 in the aluminum hydroxide group.

While the two antigens appeared comparable with respect to the diphtheria toxoid component, when viewed in the light of ability to meet the criteria set on the basis of antitoxin units per milliliter and agglutination titers, the aluminum phosphate adsorbed antigen was better than the aluminum hydroxide adsorbed antigen. In view of the multiplicity of factors that govern the occurrence of disease, including dosage of infection, specific immunity, and other resistance factors, it is difficult to establish arbitrary pertussis agglutination and diphtheria antitoxin levels above which a person is immune and below which he is susceptible. By utilizing the data in tables 3 and 4, however, one may compare the response to the antigens according to any desired combinations of pertussis agglutination and diphtheria antitoxin levels.

In general, the infants tolerated the inoculations very well. Many of the mild systemic reactions occurring within a few hours of injection were reported by the parent. Possibly, some of these were over-reported. Some of the local reactions observed by physicians and nurses, however, were unnoticed by the parent. Sauer observed a lower frequency of systemic and local reactions following aluminum phosphate adsorbed antigens than were observed

following the use of alum precipitated antigens (8). In our experience local and systemic reactions are more frequently discovered when infants are systematically observed by physicians or nurses than when the frequency of reaction is based on reports by the parent.

The results of the study support neonatal inoculation as a safe, effective, acceptable procedure. The type of antigen used appears to be of importance in view of the variations observed in response to available preparations. Furthermore, the loss of immunity as indicated by the agglutination and antitoxin levels 1 year after the third inoculation reemphasizes the need for a fourth injection or booster rose at approximately 1 year of age or earlier.

Summary

A group of infants was inoculated during the neonatal period with aluminum phosphate adsorbed or aluminum hydroxide adsorbed diphtheria-tetanus toxoid and pertussis vaccine, combined. The infants were observed up to 1 year following completion of the series of three inoculations.

Based on diphtheria antitoxin titrations, responses to the aluminum phosphate and aluminum hydroxide adsorbed antigens were comparable.

Based on pertussis agglutination titers 1 month and 1 year following vaccination, the aluminum phosphate was better than the alumi-

The charge was as high as \$1.25 in some of the business offices and stores since their vaccine was purchased at the commercial rate. A few stores absorbed the entire cost of vaccinating their employees.

The county health commissioner purchased \$36,000 worth of vaccine for the school and church clinics. Clinic sponsors reimbursed the commissioner at cost.

Publicity and Promotions

When plans for mass clinics were announced, one Salt Lake City newspaper, the *Deseret News*, carried a daily schedule of clinics that gave the time and place of all mass clinics for the coming week and information on how to schedule a new clinic with the medical society. They covered the progress of the local vaccination campaign and the national poliomyelitis situation. Thus, the mass immunization program was kept constantly before the public.

Vaccination reminders were sent to 97,000

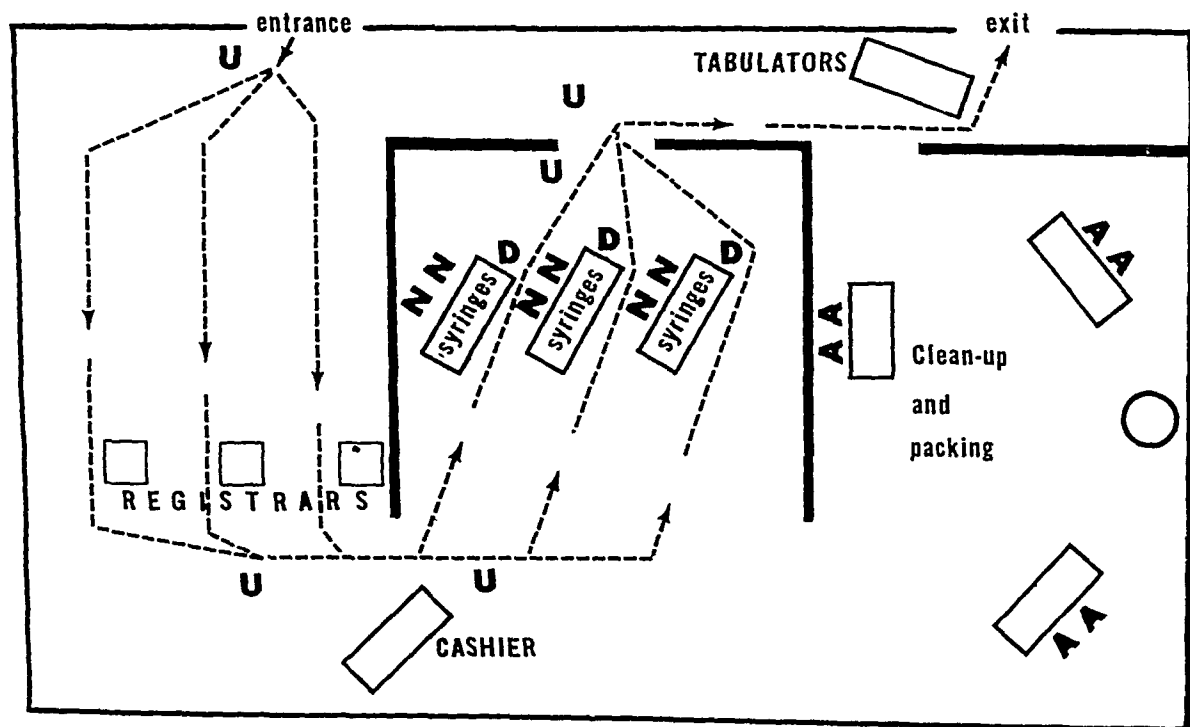

homes by 1 bank and 7 department stores along with their monthly statements. "Polio Won't Wait, Vaccinate" posters were placed in show-windows of downtown stores, utility companies, and banks. Newspaper advertisers used 1-inch squares of the same poster as inserts on their advertisements during the last 2 weeks of July.

Daily radio announcements were broadcast for the last 2 weeks of the clinics. There were six free-time, 10-minute interviews of different physicians concerning the need for Salk vaccinations.

One studio televised a "live" poliomyelitis immunization clinic for more than 100 employees. The vaccination of the employees was completed in 20 minutes by one physician, who carried on an interview while administering the injections.

As a promotional stunt, during the second school clinic, searchlights illuminated the area outside the school, and trade stamps were given with every injection. At the last clinics, free soft drinks were served.

Poliomyelitis Vaccination Campaign in Salt Lake City, Utah

JAMES E. BOWES, M.D.

ALMOST 400,000 shots of poliomyelitis vaccine were given in a mass immunization campaign in Salt Lake City, Utah, in 1957. From the inception of the campaign, arising from pressures of various civic groups early in 1957, until its end in July of that year, streams of people passed through clinics in schools, churches, department stores, and other places to receive their injections.

A total of 116,710 vaccine injections were given at clinics held in 127 schools, 25 churches, and 40 industrial firms, business offices, and stores. In addition, 275,130 injections were given in the offices of private physicians. Altogether, 62 percent of the city's residents were immunized.

The Salt Lake County Medical Society sponsored the vaccination program and appointed me as coordinator. Scheduling of clinics for all schools was begun at once through my office. Within 4 weeks all the schools and businesses that sought vaccination for their employees were accommodated. The nurses and equipment were supplied by the Salt Lake City and County Health Departments.

The first clinics were arranged for 500 employees of a major department store and for a junior high school where two students had died of poliomyelitis in 1956. For the school clinic, the PTA purchased vaccine from a local drug-gist at the commercial rate until it could be bought at the institutional price directly from drug firms.

The second school clinic was sponsored by a local Lion's Club. Newspaper and radio publicity resulted in a crowd of 2,450 persons. The challenge here was to obtain enough syringes so that there would be a separate one for each person.

The city health department had only 1,500 syringes. Four hundred more, relics of the poliomyelitis pioneer programs, were found in the basement of the State Capitol. All hospitals were asked to have syringes ready in case of need. Since the second clinic was to last from 6 p.m. until 10 p.m., the first 300 syringes used were cleaned, packed, and rushed to a nearby hospital for autoclaving and were returned for the last hour.

The problem of syringes continued to be the knottiest one of all throughout the campaign. Disposable syringes were too expensive: at 18 cents per unit, it would have meant \$180 in the waste basket for every 1,000 persons injected. Interchangeable 2 cc. syringes were best. Dr. Hingson's jet-injector, which injects 900 persons per hour would have been ideal, but it was not then available.

Monetary Considerations

When the immunization program was first considered, several physicians were opposed to mass clinics, preferring individual vaccinations in their offices. The medical society, believing that this method would fail to meet the citywide demand on short notice, agreed to a fee of \$15 per hour to be paid physicians who worked in the clinics.

At most of the clinics, each person was charged \$1, which covered the following costs: vaccine, 65¢; replacement of broken syringes, 3¢; cotton, alcohol, and acetone, 3¢; physician's fee, 7¢; and a surplus of 22¢ to allow for indigent persons. (Unused Federal funds were also allocated to purchase vaccine for anyone under 20 years of age and pregnant women. Free injections were given at the city and county health departments during August 1957. All nurses canvassed their areas and encouraged indigent groups to take advantage of this offer.)

Dr. Bowes is a private physician practicing obstetrics and gynecology in Salt Lake City, Utah.

level. Long-distance telephone calls revealed that four manufacturers favored bulk sales of vaccine to public health agencies; only small amounts were for distribution directly to physicians. One manufacturer was willing to split 50 percent of Utah's quota with commercial outlets for the private physician's use. Another manufacturer offered to make 2,000 bottles available to us immediately, on the condition that we purchase it through a public health agency.

A Salk vaccine bank was formed to provide vaccine for the mass clinics and to lend it to any physician in our county who could not obtain it through commercial sources. Responding to statewide demand, we lent 11,000 injections to 80 different physicians, 21,600 injections to 16 county health units in Utah, 140 to the Army and Air Force, and supplied 2 hospitals and 2 universities. Nearly every borrower returned the vaccine after commercial supplies were available.

School Survey

Since one of the prime objectives of the campaign was to immunize the school children in time for the poliomyelitis season, we conducted a survey to see if the objective was being met. A survey, based on the number of children present on 1 day, was conducted in all the city's 41 grade schools, 11 junior high schools, and 3 high schools.

Good immunization coverage was found in all grade and junior high schools in the upper third economic areas. However, 20 to 35 percent of the children in the poorest economic areas never received a single poliomyelitis injection. Two high schools still had 35 percent of its students without vaccinations.

A clinic was arranged in each school where there were at least 40 students present who had never been vaccinated. Since only the sixth and seventh grades were considered reliable in our survey, the need in the lower grades was estimated proportionately to the response in the upper classes.

Clinics were held during 1 class hour in 31 schools over a 3-day period. During these "mop-up" clinics, 1,980 injections were given, greatly increasing the immunization level. The

\$1 charge was waived for any child who could not afford it.

Final Phase of Clinics

For the conclusion of our program, we set up 17 city and suburban clinics in schools throughout the area. We held only 1 clinic each day, from 1 p.m. to 8 p.m., so that the full staff of city and county health department nurses and all syringes and needles would be available.

Since this period lasted 16 days, persons getting a first shot during the initial July clinics could attend one again in 14 days and receive their second injection. Dr. John G. Bachtold and Dr. Louis P. Gebhart, virologists of the University of Utah, advised the committee on the effectiveness of spacing the various injections. Since the poliomyelitis season was fast approaching, they allowed a minimum 10-week interval between the second and third injections rather than the usual 7 months.

At 9 city clinics, injections were given 17,443 persons, and at 8 suburban clinics 11,963 were vaccinated. More than 4,000 of these received their first shots. At the last clinic, held on July 31, 1957, we vaccinated 3,500 persons.

Operations

The accompanying figure depicts our flow chart when 1,000 persons were expected to be vaccinated within 1 hour's time. This rate of injections required 3 doctors, 6 nurses, 6 clerks, 6 ushers, and 6 women for cleaning and packing syringes.

The best attendance was at 6 p.m., and the worst between 2 p.m. and 4 p.m. Nurses began setting up tables and loading syringes 1 hour in advance of a specified beginning time, for it was our experience that if 1,000 persons were expected to attend, more than 100 persons were in line one-half hour before time. We started our injections ahead of time to create public goodwill.

There was no attempt to keep a registry of persons getting injections other than completing a shot-record card and tabulating the number attending.

The nursing service from the Salt Lake City

Vaccine Shortage

A vaccine shortage in March created a momentary panic in the poliomyelitis committee, for two big clinics of nearly 1,000 each had been scheduled. The *Deseret News* contacted the Public Health Service in Washington, D. C., about the shortage and found it was nationwide. Mass clinics throughout the country had exceeded the manufacturers' estimates.

Telephone calls on this black March 13 to a drug firm brought part of our back order in 4 days. The National Foundation for Infantile Paralysis gave me \$1,000 to purchase any vaccine available in the State. Only twenty 9-cc. vials of Salk vaccine were found in 24 drug-stores in 8 cities.

In the meantime, the National Foundation found 500 vials of vaccine in Reno, Nev., not being used. It was shipped by commercial airline in time for the clinics that night. A 1,200-bottle shipment came through in several days and kept us going for another month.

On April 11, another vaccine shortage occurred because of a delay in shipment. *Deseret News* officials arranged with the Utah Air National Guard to send a jet to Indiana to pick up 1,200 bottles of vaccine. The airplane made the 3,000 mile roundtrip flight in 10 hours, returning the same day with enough vaccine for that night and the next several weeks.

By mid-April, private physicians were short of vaccine. We visited a drug wholesaler and found the problem was at the manufacturers'

Poliomyelitis Vaccination in Bucks County

A Japanese print called "A Chest Full of Goblins" was used as a scary eye-catcher in a poliomyelitis vaccination campaign by the Bucks County (Pa.) Department of Health through county newspapers, beginning in early March 1958.

"Bucks County needs 400,000 more polio shots" were key words used in the opening statement of the campaign by Dr. Jackson Davis, director of the Bucks County Department of Health.

He commended the medical society of the county for its vote in February to encourage physicians to set up office hours periodically for administering poliovirus vaccine at a reduced fee, and urged a call to the family doctor to learn the hours set. Dr. Davis emphasized that "the odds are now 2 to 1 for paralysis if your child under 5 years gets poliomyelitis."

Statistical facts which he gave for the disease disclosed no confirmed cases in Bucks County in 1957, in spite of the fact that only 40 percent of the most vulnerable group, infants and children under 5 years of age, had received even one injection of poliovirus

vaccine. "Will our luck hold in 1958?" he asked.

The approximately 225,000 poliomyelitis shots that were administered in Bucks County, he pointed out, were chiefly in children 5 through 19 years of age.

A method based largely on Bureau of the Census data reveals that since 1910 considerable change has occurred in the timing and duration of the period of childbearing in the United States.

Age of Women at Completion of Childbearing

LINCOLN H. DAY, Ph.D.

MORE than 90 percent of the women in the United States eventually marry (1), and 85 to 95 percent of those who marry before the age of 45 become mothers (2). Hence, changes in the length and timing of the childbearing period may have important social effects on large numbers of American women and, through them, on the other members of society as well.

This paper will discuss an attempt we have made to determine the proportion of women who had completed their childbearing by the time they had reached certain ages. An analysis of the age-specific birth rates for women in various age cohorts could afford some indication of any change which might have occurred in these proportions; but the method is somewhat inadequate because it not only fails to denote the number of women who had completed their childbearing, but because it also gives only a very crude indication of their age distribution. The method devised by us to assemble the data for this article falls prey to neither of these shortcomings. It is, however, not entirely free of certain others of its own.

The census data from which we derived our basic information are available only for the years 1910, 1940, and 1950. For purposes of

this study it was assumed that a mother had completed her childbearing if she had not borne a child for a period of at least 5 years. Although such an assumption is not invariably true, it was necessitated by the character of the relevant data, data in which mothers were subdivided by whether they were with or without children under 5 years of age.

A partial check of the validity of this assumption was made by the use of recent data on child spacing gathered by Schachter and Grabill (3), together with data from the Indianapolis study analyzed by Whelpton and Kiser (4) and a tabulation of the estimated ages of siblings of 565 freshman scholarship candidates at Mount Holyoke College. On the basis of these rather disparate materials, it appears that not more than 20 percent of the mothers had let 5 or more years elapse between births.

Admittedly, this percentage is somewhat higher than could have been hoped for. A figure closer to, say, 10 percent would have been a better validation of the assumption upon which our study is based. However, the women in each of these three studies went through their childbearing periods during the depression and subsequent war period. The only exception, and it is but a partial one, is the group studied by Schachter and Grabill. The percentage of mothers in their group who had not completed childbearing was somewhat less than the percentage for the other groups. On the basis of

Dr. Day is assistant professor of sociology, department of economics and sociology, Mount Holyoke College, South Hadley, Mass.

and County Health Departments was indispensable. After their regular duties, the nurses spent many evening hours setting up and conducting clinics. Hundreds of volunteer nurses assisted them in keeping records, ushering, and cleaning and packing syringes and needles.

Results and Conclusions

Tabulation sheets used at each clinic provided an accurate count of the injections given. In the city, the number was 66,170, while in the county (suburbs) it was 50,540. A more detailed age distribution record, kept in the

city clinics, revealed our poorest attendance was in the group 15-19 years old. Of those over 40 years old, 11,198 were given injections even though publicity was not directed toward them.

To get an idea of the total immunization coverage in our community, we conducted a telephone survey, sampling the 88,000 private family listings in the directory. A total of 391,840 injections were given. Since the public clinics had administered 116,710 injections, the remaining injections must have been given by private physicians in their offices. An obvious conclusion may be drawn: Mass clinics do not take patients away from private physicians.

School Announcements

University of Minnesota. From July 21 through August 1, 1958, the School of Public Health will hold a workshop on radiological health in industry and the community. The course is designed for physicians, nurses, chemists, sanitarians, and others concerned with such health problems.

Topics to be covered in the workshop include: introduction to radiation; sources of radiation exposure; atomic structure; radioactivity; X-rays; interaction of radiation with matter; units of measurement; natural and artificial background; biological and genetic effects of radiation; maximum permissible levels; principles of radiation protection; and public health aspects of radiological health.

For further information, write to the School of Public Health, 1325 Mayo Memorial Building, University of Minnesota, Minneapolis 14.

Massachusetts Institute of Technology. The Institute offers a 2-week special summer program in air pollution from August 11 through August 22, 1958. Intended primarily for industrial, chemical, mechanical, and sanitary engineers who wish a better understanding of the broad concepts of air pollution control, the program will cover the meteorological

problem, toxicology and public health, aerosol technology and air cleaning, and air analysis, along with legislative and regulatory acts. No formal background, however, is required in meteorology or physiology. Academic credit is not offered. Write the Massachusetts Institute of Technology, Cambridge, for further information.

Harvard University. A new division of environmental hygiene has been added to the School of Public Health. Radiation hazards, air pollution, accident prevention, and industrial hygiene will comprise the curriculum and research activities in the new division.

University of Michigan. The department of environmental health of the School of Public Health has expanded its radiological health curriculum from 1 to 7 courses for the 1958-59 school year.

To the current course on radiological health have been added fieldwork in radiological health; radiation biology; techniques used in radioactive air, water, sewage, and stream pollution studies; radiological health seminar; disposal of radioactive wastes; and a second part of radiological health.

A method based largely on Bureau of the Census data reveals that since 1910 considerable change has occurred in the timing and duration of the period of childbearing in the United States.

Age of Women at Completion of Childbearing

LINCOLN H. DAY, Ph.D.

MORE than 90 percent of the women in the United States eventually marry (1), and 85 to 95 percent of those who marry before the age of 45 become mothers (2). Hence, changes in the length and timing of the childbearing period may have important social effects on large numbers of American women and, through them, on the other members of society as well.

This paper will discuss an attempt we have made to determine the proportion of women who had completed their childbearing by the time they had reached certain ages. An analysis of the age-specific birth rates for women in various age cohorts could afford some indication of any change which might have occurred in these proportions; but the method is somewhat inadequate because it not only fails to denote the number of women who had completed their childbearing, but because it also gives only a very crude indication of their age distribution. The method devised by us to assemble the data for this article falls prey to neither of these shortcomings. It is, however, not entirely free of certain others of its own.

The census data from which we derived our basic information are available only for the years 1910, 1940, and 1950. For purposes of

this study it was assumed that a mother had completed her childbearing if she had not borne a child for a period of at least 5 years. Although such an assumption is not invariably true, it was necessitated by the character of the relevant data, data in which mothers were subdivided by whether they were with or without children under 5 years of age.

A partial check of the validity of this assumption was made by the use of recent data on child spacing gathered by Schachter and Grabill (3), together with data from the Indianapolis study analyzed by Whelpton and Kiser (4) and a tabulation of the estimated ages of siblings of 565 freshman scholarship candidates at Mount Holyoke College. On the basis of these rather disparate materials, it appears that not more than 20 percent of the mothers had let 5 or more years elapse between births.

Admittedly, this percentage is somewhat higher than could have been hoped for. A figure closer to, say, 10 percent would have been a better validation of the assumption upon which our study is based. However, the women in each of these three studies went through their childbearing periods during the depression and subsequent war period. The only exception, and it is but a partial one, is the group studied by Schachter and Grabill. The percentage of mothers in their group who had not completed childbearing was somewhat less than the percentage for the other groups. On the basis of

Dr. Day is assistant professor of sociology, department of economics and sociology, Mount Holyoke College, South Hadley, Mass.

Whelpton's recent studies of cohort fertility (5), it is likely that this deviation of about 20 percent from our definition of completed childbearing results from the partial making up, by women born between approximately 1903 and 1915, of births postponed during the depression.

Determining the difference in years between the age by which each cohort had borne 25 percent of its births and the age by which it had borne 90 percent, it was found that the difference was greater for the cohorts of 1903-15 than for those born earlier; and that, if present trends continue, this difference will be smallest of all for cohorts born after 1915. Women born before about 1903 seem not to have "made up" for births postponed during the depression; while women born after about 1915 seem to have been little affected by the depression, so far as any necessity to make up for postponed births is concerned.

This making up of births is probably the main factor in the 20 percent deviation from our definition of completed childbearing, although there is also a certain proportion of women who bore an additional child after a period of more than 5 years in each of the census years for which we have data. On the basis of the three studies mentioned above, it would appear that most of these were women who had allowed only 6 years to elapse between successive births.

Estimation of Error

Before making estimates of the proportions of women who had completed childbearing, adjustments were made on the census data themselves in order to lessen as much as possible the chance of error arising from any source other than the basic assumption. One adjustment was for under-enumeration of births; the other, for infant and child mortality.

The 1950 data published in the census report on fertility (2) had been partially adjusted for under-enumeration; those for 1940 and 1910 had not (6a, 6b). In the appendix to its 1945 report on differential fertility (6a) the Bureau of the Census cites certain findings from a special tabulation of schedules from the 1940 census. Undertaken to obtain information on the fertility of ever-married women who had made no report of the number of children ever born

the tabulation revealed striking differences, both in the number of children ever born and in the proportion who had remained childless, between the women who had failed to report on the number of children ever born to them and the women who had so reported. By a method involving the application of two sets of fertility ratios, that is, number of children 0-4 years old per 1,000 women in a given age category, one set from this special tabulation and the other from the regular census enumeration, we were able to make an estimate of the total number of mothers in each age group who had completed childbearing in 1940. Then, on the assumption of relative equality between the respective ratios in 1940 and 1910, we made a similar estimate for the earlier year.

An example of the difference this adjustment for under-enumeration makes is shown in table 1, which compares the proportions of "completed" childbearing derived from unadjusted and adjusted census data for native whites and Negroes. The main difference is found in the earlier ages, denoting considerable under-enumeration of children born to younger mothers. In some instances this has amounted to a decrease between the adjusted and unadjusted figures of 50 percent for native whites and 30 percent for Negroes. That the proportional changes occasioned by adjustment for the effects of under-enumeration were generally larger for whites than for Negroes is due not to a more complete enumeration of Negroes, but to the relatively greater effect on the Negro data of an additional adjustment for infant and child mortality.

An adjustment for infant and child mortality was necessary because of the importance to our calculations of data on the number of mothers with children under 5 years of age. By our method, were mortality not taken into account, if a child had been born and had died within 5 years of the census the mother would be tabulated as a woman of completed fertility if she had no other children under 5 years of age, whereas if the child had lived, the mother would have been counted as a woman of uncompleted fertility. For this reason an "adjustment factor" derived from life table d_1 values (7-9) was applied to each group of mothers.

In calculating this adjustment factor, an estimation was made of the number of children born to mothers in each 5-year age group within 5 years of the census and dying before the census was taken. In its actual calculation, the adjustment factor was made a function of both the level of infant and child mortality and of the number of children born to women in each age group. The adjustment does not take into account abortions or stillbirths, although these might have been of some consequence in the duration of childbearing.

Table 2 gives a sample comparison of the difference this adjustment for mortality makes in the proportion of "completed" childbearing in each age group. As with the adjustment for under-enumeration, the largest differences are

at the younger ages. This should be expected because of the higher proportions of younger women who have borne but one child and who therefore have no other child under 5 years of age to put them in the "childbearing uncompleted" category.

From the basic findings shown in table 3, three general facts can be noted: (a) there have been changes since 1910 in the ages at which most women complete childbearing; (b) these changes have been in the direction of a greater concentration of childbearing in certain ages, that is, an earlier average age of women at completion of childbearing and a higher proportion who finish childbearing earlier, and (c) certain demographic developments during the depression decade of the 1930's differed markedly

³ Native whites only for 1940 and 1910.

from those which preceded it, and these developments have not been extensively continued since that time.

Among these findings, those for 1940 are somewhat anomalous. On the surface it would seem that the most extensive change in the direction cited was between 1910 and 1940, with a change in the opposite direction between 1940 and 1950. Evidence of a sizable change between 1910 and 1940 can be seen not only in the data under discussion but also in the cohort data collected and analyzed by Whelpton (5).

But whether a change in the opposite direction occurred between 1940 and 1950 is doubtful, in view of the information we have developed from Whelpton's data. By updating his table A for the years through 1954 and then estimating the additional parity-order births which would occur before the end of the period of childbearing, it was possible to make various calculations for cohorts born as recently as 1925. These calculations were used to estimate the ages of the cohorts at the time various proportions of their children either had been born or, for cohorts whose fertility had to be estimated, will have been born.

Obviously, these estimates are subject to error. But since they were made solely for the years near the end of the childbearing period, when but a small proportion of all births occur, even substantial errors should have only a minor effect on the total for cohorts of women born before about 1918. For those born after that date, however, the risk of error in calculations of fertility rates is greater, varying directly with the year of birth.

Despite these limitations, the pattern set by the cohorts for which more data had to be estimated follows quite closely the pattern set by those cohorts for which it was necessary to estimate few or no data. These two sets of data show that, for the cohorts in the childbearing ages in 1940, there had been a generally wider distribution of childbearing in the preceding decade than there had been for cohorts in the childbearing ages in 1950. That is, the period between, for instance, the 25th and 90th percentile births was longer for the cohorts in the childbearing ages in 1940 than for those in the childbearing ages in 1950. This was partly the result of a higher incidence of delayed marriage in the depression years of the 1930's.

If to the fact of delayed marriage we add the fact that our own data are based on the assumption that a mother has completed her childbearing if she has not borne a child for 5 years, it becomes clear that what between 1940 and 1950 appears to be a reversal in the trend toward earlier completion of childbearing may actually be something quite different. Possibly the higher percentages of women who had seemingly completed childbearing by certain ages in 1940 are largely the result of an unusually high proportion of women who, because of conditions during the 1930's, allowed five or even more years to elapse between certain of their births. The increased birth rates for women above age 35 in the late 1930's and early 1940's (10) would lend credence to this view. In short, if anything, the childbearing patterns of women tabulated in the 1940 census represent not so much an advanced stage in the trend toward a shorter period of childbearing as they do a temporary plateau or even reversal of that trend. The important comparisons, then, are those which are to be made between 1910 and 1950, rather than between either of those years and 1940.

Socioeconomic Factors

In considering the relation between childbearing and various socioeconomic classifications we are limited to three variables: race, rural-urban residence, and number of years of schooling.

In comparison with whites, there is a higher proportion of Negro women at either extreme of the childbearing process: on the basis of our definition, a higher proportion of Negro women than of white women complete their childbearing before age 35, while at the same time, a higher proportion also continue to bear children in the later years of the fecund period. Among women of both races, childbearing in the upper ages is most common among those who do not know how to prevent unwanted pregnancies or who are unwilling to accept planning in such a highly personal area of life. This condition, related as it is to low income and scant educational opportunity, is much more common among Negroes than among whites.

On the other hand, the social conditions in which many Negroes have been found to live are likely to lower fertility either through the separation of spouses, which lessens the chance of conception, or for other reasons, such as the contraction of venereal disease, which frequently leads to sterility and pregnancy wastage (11). Many persons who have lived under these conditions may eventually form stable marital relationships; but since fecundity in women declines gradually after about age 25 and more rapidly after about age 30, they may achieve this stability too late for them to bear any, or more than 1 or 2, children.

We have, then, a situation among Negroes in which the ignorance and poverty of a large number has tended to produce a generally longer period of childbearing while at the same time, a considerable amount of personal and social disorganization among others has tended to produce a generally shorter period of childbearing. Our data bear this out by showing, in comparison with whites, a higher proportion of childless Negro women, a higher proportion completing their childbearing in the younger ages, and a higher proportion continuing to bear children in the upper ages. What is unusual about childbearing among Negroes is not the fact that a certain number of women continue to bear children throughout the whole fecund period, whereas others bear only a few or none at all. The unusual character of Negro childbearing derives from the fact that it is dispersed over a wider age range than that of whites.

With respect to rural-urban differences in the proportion of completed fertility, the general trend among white women has been toward less diversity among the three available residential groupings (urban, rural nonfarm, and rural farm) in the proportion of women who have completed childbearing at any given age. The sources of this greater homogeneity are two: (a) a greater proportion of rural women are finishing their childbearing earlier than in the past; and (b) a greater proportion of urban women are finishing their childbearing later.

With the rural areas showing the greater change, the result has been a decrease in the considerable urban-rural differential which

formerly existed. The rural trend is part of a general decline in fertility; the trend in urban areas, however, seems to derive in large part from an increase in births during the "baby boom" after World War II. Were we able to compute the proportions of "completed fertility" on the basis of data for years more recent than 1950, we should probably find among urban women a partial return to the higher percentages of the pre-war years. But it is still likely that the urban-rural differentials will decline further in the future.

Although similar changes for urban and rural groups have occurred among nonwhites, there is not the degree of homogeneity that we find among whites. The differences between residential groupings of nonwhites were smaller in 1950 than in 1910, just as they were among whites. But the changes were considerably smaller among nonwhites than among whites.

Because there is in the United States considerable evidence of a close association between number of years of schooling and socioeconomic status, an analysis of data on childbearing, subdivided according to years of schooling, affords an indication of the differences in timing and duration of childbearing among the various social strata. Such an analysis must be limited to 1940, however, because data for 1910 do not exist, while those for 1950 are in a form unsuited to this kind of analysis.

Our studies show that, among both whites and Negroes, there is greater similarity between rates of completion of childbearing for mothers with the most schooling and for mothers with the least schooling than between the rates for either group and those for women with a grammar or high school education.

The reasons for the similarity in fertility rates between mothers with the most and mothers with the least schooling were quite different, however. Among women with few years of schooling the dominant pattern was one of continual childbearing, even into the upper ages; among women with some college education the pattern was generally one of later marriage. The result, at least in 1940, was a higher proportion of completed fertility at each age among women with some high school education than among the groups with either

less or more than a high school education. But because of generally smaller families, the actual number of years spent in childbearing was less for the groups with more schooling. On the average, the more years of schooling, the fewer years devoted to childbearing.

Demographic Factors

In the present study the causal factors, however numerous and diverse, and however complex their interrelationship, affect the timing and duration of childbearing through only three demographic factors: (a) average size of family; (b) age of mother at birth of first child; and (c) lapse of time between successive births. To the extent that the paucity of data permits any analysis, we have found that not all of these factors have operated in the same direction.

Despite certain tendencies which lengthen the period of childbearing, women today are finishing their childbearing at earlier ages than formerly, first, because of a decline in family size, and second, because of a generally younger age of the mother at birth of the first child.

Median family size has declined considerably since the earlier part of the century, approximately 50 percent for native whites and 60 percent for Negroes (2, 5). In the 1930's this meant a high proportion of childless and one-child families. Today it means a general increase in the proportion of families with 2, 3, and 4 children. In both instances, the change has been characterized by a continual decrease in the proportion of large families, that is, those with six or more children.

With the exception of the depression decade, the average age of the mother at birth of the first child has also decreased considerably since the earlier part of the century, about $1\frac{3}{4}$ years between 1890 and 1950 (12, 13). This is largely the result of an earlier age at first marriage, particularly since 1930.

Although the childbearing period in the United States has been shortened, the available evidence suggests that there has been a tendency in recent years for women to bear children at somewhat longer intervals. This is in keeping with the recommendations of modern obstetricians and is doubtless made possible

largely through the more widespread practice of birth control.

The increased incidence of divorce and the separation of husband and wife because of universal military conscription also apparently act more to lengthen the average period of childbearing than to decrease it through effecting any general decline in the number of children per family. This is partially compensated for to the extent that widowhood in the childbearing ages has declined. But it is our conclusion that the gain in time for childbearing which has resulted from less widowhood has not counteracted the losses occasioned by more divorce, together with separation of spouses in response to universal military conscription. The relative shortness of the 2-year term for draftees and the high remarriage rate for divorcees (14, 15) have apparently resulted, not in a smaller family size, with the attendant possibility of completing childbearing at an earlier age, but simply in postponement or prolongation of the period of childbearing among these groups.

Discussion

In this brief summary it is not our purpose to discuss the implications of a shortening of the childbearing period among American women or of a change in its timing. Such a fundamental alteration of the basic institution of the family can, of course, have far-reaching effects on various other aspects of the society and its culture. What effects these changes have will depend on the uses to which women put the added years of relative freedom from housework and child care activities.

There is some evidence of an increase in the participation of women in both politics and the labor force. This is particularly true of women from the middle and upper social strata, which may help to explain the publicity it has received in the mass media. To what extent this participation is accounted for by changes in the pattern of childbearing we cannot presently determine. Nor can we at this time do more than speculate concerning the further effects of this participation on such social phenomena as the status of women, patterns of childrearing, and the system of social stratification. But there can be little question that each of these phenomena is at least partially influenced by

the behavior of woman in her fundamental role of wife and mother, and that such behavior is to a considerable extent a function of the timing and duration of her childbearing.

Pengamats, Mantris, and Controllers

Because Indonesia's malaria control program needed intermediate supervisors, the new position of "pengamat malaria," between the ranks of "mantri" and "controller" was created. Pengamat rank gives technicians, called mantris, an additional opportunity for advancement, as well as providing middle-echelon supervision. The first class for potential pengamats has been started.

The top-ranking supervisors, controllers, are secondary school graduates who are trained in public health and malaria control for 3 years. They then spend 9 months in India, Thailand, or the Philippines in field training and observation of malaria control programs.

Before beginning their work in Indonesia, controllers are given a month's course in public administration to bridge the abrupt psychological change from student to supervisor. The concentrated course covers recordkeeping, personnel practices, job analyses, essentials of supervision, and similar subjects.

—HAROLD A. WOOD, M.D., *chief, Public Health Division, U. S. Operations Mission, Indonesia.*

Filipino Five-Year Plan

Less than a third of the 31 engineers now employed in public health and only a small percentage of the present 2,013 inspectors in the Philippine Department of Health have had specialized training in sanitation. At least 3,400 inspectors are needed. The Philippine government presently has only one sanitary engineer per 700,000 population. The needed engineers may be graduated by the Institute of Hygiene of the University of the Philippines, which granted a master's degree in public health engineering for the first time in 1957.

To prepare inspectors, pilot projects will be launched in two areas selected for both rural and urban characteristics. The projects, demonstrating good sanitary practices in water supply, sewage and

garbage disposal, and rodent control, will be carried out by the training centers where local sanitary engineers and inspectors can gain needed experience.

Three similar pilot projects, requiring a minimum of 5 years to complete, will be set up at other centers. The broad plan for environmental sanitation culminates 2 years of work by local, ICA, and WHO personnel.

—ALBERT P. TALBOYS, *sanitary engineer, U. S. Operations Mission, Philippines.*

Flowers and Privies

In Pedro Pablo Gómez, a village of 232 houses in the coastal area of Ecuador, 217 families paid for their own sanitary pit privies. Privies were installed at the rate of 14 per day.

In nearby Jipijapa, spring floods destroyed the dam which impounded the water for the public supply system. To relieve the emergency, several wells were dug by hand under the supervision of health servicio technicians. School children fenced in small areas around the wells and planted flowers and shrubs to show their appreciation.

—JAMES D. CALDWELL, *chief, health, welfare, and housing field party, U. S. Operations Mission, Ecuador.*

A Phoenix in Reyes

Three years of effort vanished when a vandal lit the fire which destroyed Reyes' newly completed hospital-health center. Fortunately, although servicio's engineering division had finished the two-story cement and wood building in the little Bolivian town, the center's equipment was not yet installed. Only the damaged walls, the sanitary system, and the tiled first floor remained.

Since building the center was the final phase of health facilities construction, Servicio Cooperativo Interamericano de Salud Pública could not assure the town of funds to reconstruct the health center. But Reyes' 2,000 people collected enough money and material to rebuild it on a more modest scale. SCISP is providing technical engineering and administrative assistance.

Previously undiagnosed illness among adults discovered through a survey in East Harlem indicates the need for expanded health education.

Multiphasic Screening Program in a Low Income Area

FANNIE I. TOMSON, M.D., M.P.H.

THE East Harlem Health District, covering an area of 1.6 square miles, lies in the northeastern corner of Manhattan Island. Of its 195,000 inhabitants, about two-thirds have low incomes. About one-half of the population are Puerto Ricans; a small percentage are Negroes.

Within the district are 3 large teaching hospitals with a total capacity of 2,289 beds and extensive outpatient services. All 3 are affiliated with medical schools and all 3 have schools of nursing. Of 408 physicians who have offices in this area, by far the majority are specialists serving the city as a whole, but 105 of them indicated that they are engaged in general practice.

In spite of the accessibility and availability of excellent medical care resources within the district and in the adjacent areas, it has been the impression of the staff at the East Harlem Health Center that the population avails itself of these resources only for emergency care and for acute illness. Unless hospitalization is indicated and made available, treatment is begun in the outpatient service and may never be completed because the patient is too ill to travel to the hospital for continued observation.

It is our impression that the home rarely provides for any medical care. This impression

is based on the broad experience of the health center's staff, gained from more than 128,000 visits by patients each year to our service facilities and the more than 8,000 field visits annually that our nurses make. For example, out of a register of 437 East Harlem residents with active tuberculosis, only 9 are under the care of a private physician.

Lack of care in the home is also evident in the large percentage of the elementary school population of 30,436 for whom the health center provides a school health service. Of 5,560 examinations of these children during the 1955-56 school year, 89.9 percent were done by school physicians of the New York City Department of Health. Except for some service provided by the city's department of welfare for its clients, no agency in the district provides free at-home medical care.

On the basis of the available rates, the East Harlem District falls into the quartile having the highest morbidity and mortality in the city. Measures for early case finding, highly desirable in any area, seem, therefore, to be particularly needed in this district. Children from infancy through high school age get a large measure, if not all, of the preventive services they receive from the child health stations and in the school health program. For adults, preventive services at the health center are limited to its chest, social hygiene, and cancer detection clinics. The hospitals provide little, if any, of this type of service.

Dr. Tomson is district health officer at East Harlem Health Center, New York City Department of Health.

In order to assay the situation to some degree, the East Harlem Health Center conducted a series of three multiphasic screening programs on three evenings in the spring of 1956. On the basis of an estimated capacity for 200 screenings an evening, we set a goal of 600 patients. Our health education campaign for 3½ months preceding the first screening night included letters to all suitable community agencies and organizations, press releases in English and Spanish, and, on request, speakers for scheduled meetings. Posters were distributed throughout the area. The staff of the center was asked to refer East Harlem adults who were not already patients at one of the three clinics

It is noteworthy that 306 of the 435 patients (70 percent) were referred to the center by a parent-teacher association from a single school in the area. This parents' group from a school with 1,633 students, 95 percent of them Puerto Rican, was active in spreading information about the survey and in urging members to participate. This group received a good orientation on what to expect on the screening nights and on the course of the subsequent followup.

Methods and Criteria

At the screening sessions a total of 435 persons were examined. A maximum number of nine diagnostic procedures were available to a patient. Only 16 persons had all 9 tests, and only 10 persons had fewer than 5. The average number per patient was 6.

The patients were weighed and measured, and a panel of physicians checked their skin, mouth, eyes, and mucous membranes, and gave them a quick nutrition evaluation.

Chest X-rays were taken on 70-mm. film, following the standard procedure set up by the New York City Health Department's bureau of tuberculosis. Persons with unsatisfactory or suspicious X-rays were recalled for a standard 14" by 17" X-ray and followup in the chest clinic. Cardiac pathology was picked up by the same service.

Blood specimens were drawn for serologic and blood sugar tests. The Mazzini test was used to screen for syphilis in accordance with the standard procedure of the health department's bureau of preventable diseases. The Kolmer and VDRL tests were done on positive

reactors. If these tests were positive, the person was recalled to the social hygiene clinic for a history and a physical examination as well as a repeat serologic test.

Tubes containing potassium fluoride were used in the blood sugar test. The time of the last meal was obtained. Since the screenings were held in the evening, the tubes were refrigerated overnight and analyzed the following morning in the laboratory of the diabetes detection clinic of the Brownsville Health Center. These criteria, used by the diabetes detection clinic, were followed:

<i>Hours since last meal</i>	<i>Screening level for blood sugar (mg.)</i>
Less than 2-----	130
2 to 3-----	110
More than 3-----	100
Not known-----	130

Self-obtained Papanicolaou smears were submitted by the women. These were stained and examined in the cancer detection clinic according to the standard procedure set up by the city's Adult Hygiene Bureau.

Physicians took the blood pressures. We set up this guide for recalls:

<i>Age of patient</i>	<i>Systolic mm. Hg.</i>	<i>Diastolic mm. Hg.</i>
Under 30-----	130	90
30-39-----	140	90
40-49-----	150	90
50 or over-----	150	100

On recall, persons were retested by physicians in the center's clinics or by the district health officer. When high readings persisted for those with suggestive history or symptoms, the patients were referred to treatment agencies.

For the eye tests, an ophthalmologist was provided to the survey by the glaucoma research division of the New York Association for the Blind. The ophthalmologist used the Berens-Tolman hypertension indicator, which picks up tension of 25 mm. Hg. or more. Individuals with this reading were recalled for a history and referred to a treatment agency. In addition to glaucoma, the ophthalmologist reported a number of other eye conditions which he incidentally diagnosed.

The National Society for Prevention of

Blindness supplied technicians to conduct near vision tests. They used the Lebohnson chart at a distance of 14 inches. Patients with a visual acuity of less than 14/21 with or without their glasses were referred for followup. The technicians also carried out field vision tests using the Harrington-Flocks multiple pattern field screener.

Since our regular health department services supplied most of the staff, all of the supplies, the laboratory work, and the followup and voluntary agencies provided the staff for the eye examinations without charge, the cost of the screening evenings is impossible to estimate with any degree of accuracy.

Survey Findings and Followup

All but 33 of those screened were East Harlem residents. Although the survey was especially scheduled in the evening for the convenience of working people, only 114 of the participants were men. Nearly 70 percent (303) were Puerto Ricans; 7 percent (31) were Negroes.

There was a wide age range, but 354 persons were 20-49 years of age because such a large percentage of the screened population came from the parents' group. Five were under 20, and 10 were 70 or older. During the followup we learned that of the 286 persons who gave data on their incomes, 250 claimed a weekly per capita income of less than \$20. The median, excluding 37 cases on welfare, was \$12.24. The average family had 4 or 5 members.

A relatively high percentage of positive findings were expected in this population, but the results far exceeded expectations (table 1). The survey found 525 defects in 312 of the persons examined. Only 123 were completely negative, and this fact was reported to the screenee's private physician, if he had named one, or the screenee was notified by mail (table 2). Relatively serious defects, previously unknown to the participants, were found in 131 (30 percent) of the screened group (table 3).

None of the 312 found to have one or more defects received this information by mail. The findings were reported to a private physician, if his name had been given, or the person was given an appointment at the health center. If any of the defects fell in the area of any one of the health center services, which include chest,

social hygiene, and cancer detection, the patient was recalled by the clinic, advised about all of the positive findings, and referred for treatment.

¹ This does not include persons who needed referral for further treatment for a known pathologic condition such as cancer of the cervix, and who needed further persuasion to accept supervision and care.

² Indicates conditions in which the diagnosis was confirmed on followup. For all other conditions the persons were referred directly to treatment agencies.

Patients whose defects fell in a category for which the health center had no clinic service received an interview with the health officer and conference nurse. Previous knowledge of the condition and treatment status was determined and referral for further followup was made on the basis of need.

On the screening night, only 58 persons gave the name of a private physician to whom we could report the findings. In subsequent interviews of 358 persons during clinic followups or home visits, sometimes both, 117, or one-third, indicated that they had a doctor to whom the family at least occasionally went for treatment. Forty-four percent (156) used 1 of the 3 hospitals in the district, the majority, 117, the municipal hospital; 26 gave the name of a hospital outside of the district; and 59 said the family knew no treatment agency.

Some of the district's difficulties in followup can be gauged from the fact that the mail was returned "not found" for 24 patients. Most of these were traced by 2 medical students who

made home visits in July and August, but 9 were never located. What seems especially remarkable is that, although the patients spent several hours undergoing examination on the survey nights, not more than a handful came in or called up to inquire about the results.

During the summer of 1956, two 3d-year medical students visited the homes of 226 of the individuals who had participated in the program. Thus further information was obtained about the patients' previous awareness of pathology, current treatment status, other illnesses, treatment agencies used, family income, and number in the family. Language difficulties, evasiveness, and sometimes the obvious fact that the person interviewed did not know the answer to a question made some visits unsatisfactory, and we felt that statistical evaluation could not be applied to the answers. Only 125 visits were satisfactory and gave us valuable information otherwise not obtainable.

Summary and Conclusions

In the spring of 1956, three evening multiphasic screening sessions with nine tests available were held in the East Harlem Health Center. Of 435 individuals participating, all but 33 were residents of the district. Only 123 persons did not require recall. A total of 525 defects were found in 312 persons; 131 of these had relatively significant pathology of which they had no prior knowledge.

The findings of this survey suggest the incidence of a high degree of undiagnosed illness in the low-income, adult population of the district. Further investigation is needed to determine the size of the problem in this and other population groups. This type of investigation should be particularly rewarding because so many of the illnesses and defects found in the survey lend themselves to amelioration and cure.

Consideration should be given to the extent and manner in which the community should make available expanded facilities for diagnosis and followup. Perhaps of greatest importance is the need for health education designed to increase the individual's awareness of the existing services and facilities and to raise his standards for positive health.

In a recently established research program, the National Office of Vital Statistics is developing sampling survey methods and conducting studies to collect supplementary data "anchored to vital records."

Expanding and Improving Vital Statistics

MONROE G. SIRKEN, Ph.D., and HALBERT L. DUNN, M.D.

VITAL STATISTICIANS generally think of their program as consisting of two related parts, registration and statistics. Traditionally, "statistics" has meant tabulation of data derived routinely from registration certificates. These tabulations may be considered basic vital statistics. To meet a growing demand for additional data, the concept of vital statistics is being expanded to cover supplementary statistics anchored to the vital records.

The increasing demand for supplementary vital statistics is not difficult to understand. Vital events are crucial in people's lives, and consequently they are central to many other events. Economists, demographers, and social scientists are among the host of nonhealth users of basic and supplementary vital statistics. In public health, the demand for supplementary vital data has been stimulated by the growing concern with chronic diseases, which has created interest in studies that relate the person to his total environment.

The demands for more vital and related statistics presently exceed our ability to supply them. With a few notable exceptions, such as

tabulations of multiple causes of deaths, we have pretty well exploited the items on the vital records. We do not mean to imply that all possible applications are being made of our tabulations of basic vital statistics; this is not the case. We mean merely that there is little possibility of developing tabulations of vital statistics involving new variables from the data now provided on the vital records.

How, then, should we proceed in developing new vital statistics as needs materialize? It is natural to think first of the possibility of adding new items to the vital records, but the prospects here are not encouraging. The records are legal as well as statistical documents; they cannot be encumbered with what the legal mind regards as extraneous. In fact, vital statisticians themselves would be reluctant to add too many new items or certain items. If we should ask the physician, the hospital staff, or the funeral director to provide routinely a lot of supplementary information, the request might endanger the quality of the basic data they are now providing. Furthermore, the possibility of getting more vital data by revising the vital records is not good because our system binds us to infrequent revisions.

Even if we could overcome these difficulties, we would find it inefficient routinely to collect supplementary information on the vital record itself because it is rarely necessary to obtain such information for every vital event, be it birth, death, marriage, or divorce. Because of the sampling errors that can be tolerated,

Dr. Sirken is chief of the Actuarial Analysis and Survey Methods Section, National Office of Vital Statistics, Public Health Service. Dr. Dunn is chief of the National Office of Vital Statistics. This paper is adapted from a talk Dr. Sirken gave at the 1957 meeting of the Southern Branch of the American Public Health Association and the North Carolina Public Health Association.

the collection of supplementary information can usually be confined to a relatively small subsample of the appropriate events occurring in a specified time period. In most studies, supplementary information is applicable only to a subset of events such as deaths due to selected causes or births of specified weights. Moreover, the information is needed for a single year or less or on a cyclical basis less frequently than annually.

The kinds of supplementary vital statistics that are being requested can be grouped according to their uses into three main categories. One, supplementary vital statistics are of administrative value in planning or evaluating a program, say statistics on the circumstances of fatal accidents in planning an accident prevention program. Two, such data are used in epidemiological studies to search for the etiological determinants of disease; for example, to relate cancer to cigarette smoking or fetal deaths to radiation exposure of the parents. Three, in population studies they are used in combination with information collected from other sources to get an accurate picture of what is going on in the general population. Thus, data on hospital utilization by persons who die during the study period are combined with comparable information collected from household surveys to get unbiased estimates of total hospital utilization for the exposed population.

The foregoing exemplify types of supplementary statistics related primarily to expanding the scope of vital statistics. Another important use of supplementary data is to evaluate and improve the quality of vital statistics. For example, inquiries are being made into the diagnostic evidence on which medical certification of death is based. In another study, the concept of usual place of residence as applied to tabulations of mortality statistics is being evaluated on the basis of supplementary information covering the lifetime residences of the decedent.

Since the lack of knowledge concerning methods of collecting supplementary data is probably the chief deterrent to expansion and improvement of vital statistics, the National Office of Vital Statistics of the Public Health Service has recently initiated research on

sampling survey methods as applied to this field. It is hoped that the continuity of research assured by this new activity will contribute to the development of appropriate methods and stimulate interest in others to do likewise.

Record-Anchored Studies

NOVS feels that studies anchored to the vital records hold the most promise of success in getting the needed supplementary data.

What is meant by "studies anchored to vital records"? These are studies in which the universe is defined by registered vital events. The records of appropriate vital events are the basic units, and supplementary information is collected for a sample of these units. Three main types of studies anchored to vital records are (a) the retrospective, or followback, study, (b) the cohort study, and (c) the record-matching study. In followback and cohort studies, supplementary data are collected by conducting surveys. The followback study is based on information collected in a single survey, whereas the cohort study entails collecting information for an identical set of persons on two or more occasions. In the record-matching study, the death certificate or other vital record of a person is matched with his other records, such as the census enumeration or OASI record.

The record-anchored method of collecting supplementary vital statistics has several good features. First, complete files of vital records are available for the Nation, for each State, and for communities; from these, all cases of rare vital events and probability samples of less unusual events can be readily selected. Second, basic facts concerning the vital event are contained in the vital record and therefore need not be collected again. Third, the established vital statistics system provides an operating organization for conducting these studies.

According to NOVS experience, studies anchored to the vital records are generally problem oriented. The data are usually collected for specific purposes such as estimating the amount and kind of hospital care given to persons during the year before death or testing hypotheses associating respiratory cancer with cigarette smoking. Consequently, the survey design is tailormade, as are the decisions regard-

ing the size of the sample, the type of questionnaire and kinds of questions, and the sources queried for information. As has been indicated, each of these surveys is usually of short duration. However, the possibility of establishing a continuous sampling procedure for conducting retrospective and cohort studies to collect certain kinds of supplementary information routinely and other kinds on a one-time or cyclical basis deserves consideration.

This brings us to consideration of the question, what are the most efficient ways of conducting the record-anchored studies to collect the needed data? An answer to this question requires consideration of costs and of sampling and response errors associated with collection of the information.

During the past year, NOVS has been developing optimum procedures for conducting retrospective studies anchored to the death certificate. The first methodological study, the Pennsylvania mortality study, tested procedures for collecting supplementary information about decedents by the retrospective method (1).

Data Collection Procedures

The Pennsylvania mortality study was sponsored by NOVS and the National Cancer Institute, Public Health Service, in cooperation with the Pennsylvania Department of Health. Undertaken primarily to determine procedures for conducting retrospective studies of decedents, it also served as a pilot test for an epidemiological lung cancer study in which smoking and residence histories were to be collected retrospectively for a nationwide sample of deaths. Physicians were requested to supply information about the diagnostic procedures on which they had based their certification of the causes of death. Relatives or close friends were asked to supply information about the smoking habits, residence, and job histories of the deceased.

More than 1,700 deaths were selected from those registered with the Pennsylvania Department of Health during May, June, and July 1956. Included were all lung cancer deaths, about 600, occurring during the 3-month period; for these the Pennsylvania Department of

Health provided copies of the death records. The remainder were a sample of the deaths from other causes selected at NOVS from Pennsylvania's monthly shipment of death certificates in the 10 percent current mortality sample. (The current mortality sample is a 10 percent systematic sample of death certificates received each month in the vital statistics offices of the 48 States, the District of Columbia, and 3 independent registration cities—Baltimore, New Orleans, and New York. Each month, the vital statistics offices send copies of the death certificates in the sample to NOVS.)

Collection of data for each death began with a mail query to the funeral director requesting the name and address of the certifying physician or for identification of the family informant if this information was missing, incomplete, or illegible on the death certificate. Next, the medical certifier of each death was sent a query by regular mail. Followup letters by regular and then by certified mail and telephone reminders for nonresponding physicians were the subsequent steps.

The original query to the certifying physician stated that the family informant would be asked for supplementary information about the decedent unless the certifier advised against it. Such advice was given rarely, and relatives or friends of virtually all decedents were queried. The survey of informants was initiated with a regular mail query, and followup actions included both regular and certified mailings. Personal interviews were conducted on a subsample of nonrespondents who lived in standard metropolitan areas.

Unusually high response rates in the Pennsylvania mortality study indicate the feasibility of collecting data by means of retrospective studies anchored to the death records. More than 95 percent of the certifying physicians eventually answered the queries. More than 85 percent of the family informants answered the mail queries, and the response rate was increased to 95 percent by means of the personal interview.

Another phase of the study, not yet completed, consisted of personal interviews with a random subsample of about 300 family informants living in standard metropolitan areas who had answered the mail queries. The purpose of these interviews was to measure the quality of infor-

mation reported by mail by comparing it with responses given in the personal interviews.

Other NOVS Objectives

In addition to the activities related directly to basic methodological research, two other objectives of special interest are included in NOVS's program for supplementing vital statistics. First, NOVS hopes to establish a service to provide technical consulting assistance on these matters to other agencies, including State and local health departments. Second, a survey-operations unit has been established for conducting survey studies to supplement and improve vital statistics. NOVS, in collaboration with other agencies, is currently undertaking one such survey and is planning another for 1958. The first, a joint project with the National Health Survey Program, is an illness study of deceased persons in the Middle Atlantic States. The second, which NOVS is undertaking for the National Cancer Institute, is a national lung cancer mortality study based on lessons learned from the Pennsylvania mortality study.

The national lung cancer study will use for the first time a procedure that may be called *dual sampling*. Corresponding data will be collected for a sample of vital events and for a sample of the exposed population in order to obtain estimates of vital rates. The national lung cancer mortality study will comprise one phase of a national lung cancer study that includes collecting information on smoking habits and residence history for both a national sample of lung cancer deaths and a sample of the national population. The information for a sample of the national population will be collected by the Bureau of the Census as a supplement to its current population survey. National estimates of lung cancer mortality rates in association with smoking habits and places of lifetime residence will be derived from ratios of the two sets of data.

NOVS will need the assistance and cooperation of State health departments in conducting national studies anchored to the vital records. What we have in mind is the kind of relationship that NOVS had with the Pennsylvania Department of Health in the Pennsylvania mor-

talidity study. Most important was the fact that the State health officer endorsed the study. Also important was his assistance and that of his associates in the health department in obtaining the endorsement of the State medical society.

The national lung cancer mortality study will entail following back on a relatively small number of lung cancer deaths selected from the death records sent to NOVS in the 10 percent mortality sample. The study has been endorsed by the Association of State and Territorial Health Officers. However, it cannot be completely successful without the approval of health departments in the 52 independent registration areas in the continental United States. We feel confident of Federal-State cooperation in this study in view of the long-standing cooperative relationships between NOVS and State offices of vital statistics.

Conclusions

At the beginning of this paper, we spoke of three activities of vital statistics programs: registration, production of basic vital statistics, and production of supplementary vital statistics. We believe that there will be a considerable increase in the research use of vital records at the local, State, and national levels, particularly as the records serve as focal points in sample surveys to collect supplementary vital statistics. Consequently, the activities of vital statisticians in this area will increase. It will be important, however, to continue to pay close attention to the other activities as well. Survey studies anchored to vital records may be visualized as the superstructure of the vital statistics system. Registration practices and the compilation of basic statistics are the foundation. Of necessity, the foundation must be kept in good repair in order to serve the needs for continuous series of the basic statistics and to support the supplementary statistics.

KB cells, easy to obtain and inexpensive to grow in tissue cultures, were used as successfully as monkey kidney cells for the isolation and identification of polioviruses.

Tissue Cultures of KB Epithelial Cells for Poliomyelitis Virus Tests

LAURI LUOTO, D.V.M., M.P.H., and EDGAR G. PICKENS

PUBLIC HEALTH laboratories are often called upon to test various human specimens for polioviruses. A variety of human and monkey cell cultures are employed (1) for this purpose, but their use presents certain limitations for small laboratories operating on limited budgets or those at some distance from biologic supply firms. The use of such cells requires ready access to a source of materials and may prove expensive. The cultivation of certain cells, such as the HeLa cell, by serial passage, has proved troublesome at the Rocky Mountain Laboratory and other laboratories. Utilization of a cell line that can be more easily grown by serial passage, such as the epidermoid carcinoma, strain KB (2), which is susceptible to poliovirus (3), offers advantages of availability, economy, and convenience.

This paper describes a method for growing KB cells serially in tissue cultures and the results obtained in tests for the isolation and identification of polioviruses.

Material and Methods

KB cells grown and maintained as stock cultures in square 16-ounce bottles were transplanted to smaller containers for test purposes. Stock bottles seeded with 3 ml. of a cell suspension (approximately 3,600,000 cells) and 14 ml. of growth medium yielded confluent sheets of closely packed cells suitable for transplant-

ing after 7 days' incubation at 36° C. These cells were trypsinized, centrifuged at 600 rpm for 10 minutes, and resuspended in a volume of medium 8 times that of the original cell inoculum. Thus, each stock bottle yielded 24 ml. (8 x 3 ml.) of transferable cell suspension. For use in tests, 2-ounce prescription bottles were inoculated with 0.5 ml. (600,000 cells) of the cell suspension and 10 ml. of medium. When test tube cultures were prepared, each tube received 1 ml. of the suspension diluted 1:20 in medium (60,000 cells).

Growth medium, 90L, for the KB cells consisted of Scherer's maintenance solution (4) containing 0.5 percent lactalbumin hydrolysate, 10 percent horse serum, and 125 units each of penicillin and streptomycin per milliliter. Cultures were ready for use after 3 days of incubation when bottles contained scattered islands of proliferating cells and tubes contained nearly confluent sheets of cells. Prior to inoculation with test specimens, the growth medium was replaced with medium 95M which consisted of 90L diluted with an equal volume of maintenance solution. To avoid heavy growth and

An adviser to WHO for Q fever surveillance, Dr. Luoto is chief of the Tissue Culture Section, and Mr. Pickens is a research technician, National Institute of Allergy and Infectious Diseases, Rocky Mountain Laboratory, Hamilton, Mont. Joe C. Ayers provided technical assistance in these studies.

consequent overcrowding of cells, test cultures were used within a few days. Stock cultures of KB cells could be stored for several weeks at 28° C.

Cultures also were prepared from trypsinized rhesus monkey kidneys (5). MK cells were planted in 2-ounce or 16-ounce bottles, or in test tubes, in Hanks' solution (6) containing 0.5 percent lactalbumin and 5 percent horse serum. This medium was replaced after 5 days incubation with a similar one containing 5 percent calf serum instead of horse serum, and an additional 20 ml. 4.4 percent NaHCO_3 per liter of medium. Before using the cultures, when grown to yield confluent sheets of cells after 7 to 10 days of incubation, the latter medium was replaced with a similar one containing only 2 percent calf serum but an additional 20 ml. NaHCO_3 .

Prototype and types 1, 2, and 3 polioviruses were titrated in tube cultures of KB and of monkey kidney cells. One-tenth milliliter aliquots of tenfold dilutions of virus were inoculated into 6 tubes per dilution and the cultures were observed for 7 days for virus-induced cytopathogenic changes. Titers of virus obtained with the respective cells were calculated (7) from the highest dilutions which produced cellular changes.

Neutralization tests for identification and typing of polioviruses were performed (5) in both cell cultures with poliomyelitis antisera from hyperimmunized monkeys. Neutralization of virus activity by pooled or by type-specific antiserum within the 4-day observation period was the basis upon which agents were identified as poliovirus or a type thereof.

Isolation of polioviruses from human specimens was attempted with both KB and monkey kidney cell cultures. Human fecal specimens were prepared as 20 percent suspensions in saline and centrifuged at 8,000 rpm for 30 minutes. Supernates, to which 125 units each of penicillin and streptomycin per milliliter had been added, were inoculated in 0.4-ml. amounts onto cultures. Throat washings, collected in 20 ml. of 1 percent bovine albumin in Hanks' solution with antibiotics, were inoculated in 1 ml. amounts. Daily for 7 days, cultures were examined microscopically for cytopathogenic changes; changes observed in

second passage cultures were considered specific. Viruses in such culture fluids were then differentiated in poliomyelitis-neutralization tests. If a discrepancy occurred in the test results between the MK and KB cultures, the test specimens were retested in cultures of both cells. Data on original tests of most specimens on monkey kidney cells were obtained through Dr. Carl L. Larson and William Wicht, Rocky Mountain Laboratory.

Results

Results of titrations of 9 suspensions, representative of 3 types of virus, indicated that both tissue-culture systems were of approximately equal sensitivity for the detection of polioviruses (see table). In tests of virus dilutions

near the end point, changes were sometimes noted earlier in monkey kidney cells than in KB cells, possibly because the irregular shape of the former cell permitted easier detection of changes. Differences noted were not significant, however, since cellular changes were essentially identical within several days. Alterations induced in KB cultures were similar to the progressive changes observed in monkey kidney cultures. Individual cells rounded into refrac-

tile spheres which detached from the glass surface until the entire culture was destroyed.

Eighteen known polioviruses, 3 prototype and 15 recent isolates, previously identified in monkey kidney cultures as types 1, 2, or 3, were retested in KB cells with type-specific and pooled antisera. In every instance type-specific and pooled antisera caused clear-cut neutralization of virus. Results of these tests were identical with those previously obtained with monkey kidney cultures.

Identification of 80 recently isolated viruses of mixed species was attempted by neutralization tests in which only pooled poliomyelitis antisera were used. Thirteen agents were identified as polioviruses with both MK and KB cells. The remaining 67 viruses were not inactivated by the antisera when tested in either cell type. Apparently KB cells are as effective as monkey kidney cells for identification of polioviruses inasmuch as all 13 known polioviruses and 67 nonpolioviruses, subjected to tests in both cells, were accurately differentiated with KB cultures.

Approximately 300 suspensions of feces or throat washings were tested for the presence of cytopathogenic agents. Viruses were detected in 29 specimens when monkey kidney cells were used and in 62 specimens when KB cells were employed. Of the agents isolated, 22 in monkey kidney cultures and 24 in KB cells were polioviruses. These isolations were made from the same specimens except in the two instances where cytopathogenic effects appeared only in KB cells.

Agents other than polioviruses were detected in 38 specimens tested with KB cultures and in 7 of the same specimens with monkey kidney cells. Thus, the KB cells detected all polioviruses or other viruses that were isolated from human specimens with MK cultures.

Discussion

KB cell cultures used for the isolation or propagation of viruses should consist of a dispersed cell pattern so that cellular changes caused by virus can be detected readily. Cultures containing heavier growth or confluent cells can be used with polioviruses, which produce rapid and complete degeneration of cells.

When viruses that are slow growing or that produce minimal cytopathogenic changes are cultured, the use of confluent cells may result in overcrowding and loss of cell detail, interfering with the detection of changes if tests are to be held longer than a week. Suitable cultures are easily prepared and quickly available if containers are inoculated with appropriate numbers of cells.

The sensitivity of KB cells to polioviruses, as demonstrated in titrations, in neutralization tests, and in isolation of the virus from naturally infected specimens, indicates that this cell may be substituted for or used to supplement MK cultures now used for these purposes. Also, KB cells appear more susceptible than monkey kidney cells to many nonpolioviruses. This observation will be considered fully in another paper.

Summary

Cultures of KB cells were as sensitive as cultures of monkey kidney cells in titrations of 9 suspensions of polioviruses representative of the 3 antigenic types. Eighteen known polioviruses were accurately identified by neutralization tests with KB cells. When 80 unidentified viruses were subjected to neutralization tests with poliomyelitis antisera, 13 polioviruses detected by monkey kidney cells were also identified by KB cells. In tests of 300 human-fecal suspensions or throat washings, 22 polioviruses detected in cultures of MK cells were also isolated in KB cells. Since cultures of KB cells can be propagated serially, they are less expensive and more readily available than monkey kidney cells commonly used for the isolation and identification of polioviruses.

State Mental Health Legislation in 1957

Broad expansion of community mental health services took place during 1957 as a result of the large volume of State legislation aimed at stimulating mental health programs in the communities and at improving conditions for the mentally ill.

During that year, according to reports received by the National Institute of Mental Health, Public Health Service, California, Minnesota, New Jersey, and Vermont passed laws providing grants-in-aid for community mental health services. Such legislation had been passed by Connecticut, New York, Pennsylvania, Indiana, Tennessee, and Florida in previous years.

Laws authorizing counties to levy taxes or to appropriate funds to support local mental health centers were passed by Iowa, Kansas, and South Dakota in 1957.

States and Territories which took steps to modernize laws governing commitment, detention, care, and treatment of the mentally ill were California, Colorado, Kansas, Minnesota, Montana, North Dakota, Texas, and Alaska.

Legislative action in Connecticut, Maine, Minnesota, New Hampshire, Oregon, Rhode Island, and West Virginia ratified the Interstate Compact on Mental Health, already subscribed to by Massachusetts, New York, and New Jersey. For care and treatment of the mentally retarded, Arkansas, Nebraska, and Texas authorized the construction of new institutions, the State of Washington set up a diagnostic and training center, and New York is planning a research institution. Idaho and Minnesota made it mandatory for local school districts to provide instruction for such handicapped children.

In Washington, a resident treatment center for emotionally disturbed children is being set up for research and treatment and a center for such children has also been authorized in Minnesota.

For juvenile delinquents, a special program of intensive treatment in California is being initiated in two institutions of that State. Among the States taking action to expand research and training were Texas, North Dakota, Iowa, and Ohio, where a research program in alcoholism was set up at the College of Medicine of the Ohio State University.

National Food Conference

Neglect of breakfast was observed to be the main cause of poor nutrition by several speakers at the National Food Conference in Washington, D. C., on February 24, 1958. Fears and discomfort were also discussed as major causes of poor feeding habits.

Almost every age group and both sexes consume inadequate amounts of nutrients, several of the speakers stated. High on the list of ill-fed, however, were teen-age girls and women 30 years of age or older, including many who fear the cosmetic effects of fat.

Adelia M. Beeuwkes, associate professor of public health nutrition at the University of Michigan, pointed out that teen-agers in every section of the country are failing to eat all the nutrients recommended for good health. She said there is a vital need for a nutrition education foundation in order that industry can present to the public a coordinated effort relating to all the foods necessary for normal nutrition.

Elmo Roper, market research consultant, observing the same conditions as Professor Beeuwkes, said that a large number of teen-age girls, apparently emulating their mothers, either skip breakfast or fail to eat a balanced one. "Part of the answer," Roper said, "lies in fear of weight. Part seems to lie in circumstances surrounding the eating of breakfast. Eating alone, eating in a hurry, a poor night's sleep, for example, all work against eating a good breakfast."

The older females get, the more they lean to poor diets, observed James H. Hilton, president of Iowa State College. Only 27 percent of girls 6-8 years old do not have a proper diet, but 89 percent of women 30 years old and older are not eating well.

Referring to a study of 681,000 women in Iowa who were 30 years old or older, Hilton said that "the diets of one-half to two-thirds of the

women were lacking in calcium, ascorbic acid, or vitamin A. About one-third of the diets were deficient in protein."

Deficiencies of this kind in the diet, Hilton added, might account, at least in part, for such things as fatigue and emotional instability of which the women in the study complained.

Roper provided additional information on women between 21 and 30 years of age. In a survey, a sample of these young women were asked to list everything they had eaten in one day. Their answers were classified according to the Department of Agriculture's basic 7 groupings. Only 3 percent of the women met the recommended requirements.

Hilton and Roper were in accord that the public must be educated in good eating habits rather than in the nutritive values of food. The failure in this country, Roper said, is not the supply of proper foods or the money to buy them. Nor is the public "unsympathetic to the objectives of proper eating." The public has simply failed to act upon its knowledge.

Hilton and Roper also emphasized the importance of continuing nutritional research. The effects of the working mother on the family diet, the uncongeniality and hastiness of meal-times, and the rapid changes in the preparation of food must be taken into account, Hilton said, along with the "ethnic, environmental, economic, and social origin of the people," in nutritional research.

Miriam E. Lowenberg, head of the foods and nutrition department of Pennsylvania State University, observed that children can be fed better and more wisely if they are viewed as individuals with certain capacities and preferences.

Practical considerations, she said, should guide us in the proper feeding of children. Some of the considerations she discussed were:

A 2-year-old child is able to eat approximately two tablespoonfuls of most vegetables and meat and twice that amount of soup or dessert. One should therefore avoid giving him adult portions.

If a child is served less food than he can actually eat, he feels successful when he has eaten everything set before him and he may even ask for more.

Mothers should select food that youngsters can pick up. They should allow children to eat with their fingers, she said, so that the child need not feel insecure because of awkwardness with fork and spoon.

Children prefer simple dishes and mild flavors, Dr. Lowenberg added. They have no desire to try new foods or strong seasonings.

Children 2 to 6 years old are sensitive to the texture of foods, prefer crispy foods, such as raw vegetables. They seem to enjoy the noise of chewing, she said. They dislike gummy textures or very dry food. Children under 7 do not particularly enjoy food that they have to slice, for they cannot easily use the knife.

If practical considerations are followed, Lowenberg concluded, satisfying eating habits can be instilled in the healthy child.

films

Aedes aegypti Survey Techniques

35-mm. slide film, color, silent, 82 frames, 1957.

Audience: State, county, and local mosquito control personnel.

This film documents techniques and procedures used in a population survey of *Aedes aegypti*, vector of yellow fever and dengue.

The frames show (a) orientation and briefing of mosquito control personnel before the survey; (b) selec-

tion of areas to be sampled; (c) types of equipment used; (d) various habitats of the mosquito; and (e) larvae sampling and methods of collecting adult mosquitoes.

The print may be obtained on short-term loan (United States only) from the Communicable Disease Center, Public Health Service, 50 7th Street NE., Atlanta 5, Ga., or by purchase from United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

Collection and Shipment Of Insects

35-mm. filmstrip, color, sound, 9½ minutes, 70 frames, 1957.

Audience: Students of biology, sanitarians, and pest control operators.

This filmstrip shows the correct methods of collecting, preserving, and shipping insects and certain other arthropods to be identified by specialists. These techniques include methods of pinning and labeling, with pertinent data, and packing for shipment.

The film is available on short-term loan, United States only, from the

Communicable Disease Center, Public Health Service, 50 7th Street, NE., Atlanta 5, Ga., and by purchase from United World Films, Inc., 1445 Park Avenue, New York 29, N. Y.

Engineering Your Health

16-mm. film, color, sound, 13½ minutes, 1958.

Audience: Freshman and sophomore college students, junior and senior high school students, science teachers, vocational guidance counselors, PTA groups, civic clubs, and television viewers.

Looking forward to emerging and expanding responsibilities, this film describes the problems, the needs, and the research and operational aspects of the Division of Sanitary Engineering Services programs in water pollution control and water resources, atmospheric pollution research, and radiological health. Also included are references to the various pursuits in sanitary engineering—teaching, travel, research, operations, and so forth.

The film is available from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.; the Film Library, Communicable Disease Center, Public Health Service, 50 7th Street NE., Atlanta 5, Ga.; or engineers in the Department of Health, Education, and Welfare regional offices.

Systematic collection of epidemiological data on suicides may help in understanding the causes of suicide. The study also concludes that the family physician is in a key position to recognize the potential suicide and refer him to psychiatric resources as a hygienic precaution.

Study of Suicide in Philadelphia

JACOB TUCKMAN, Ph.D., and MARTHA LAVELL, M.S.S.

SUICIDE is an important and pressing problem. The figure of 141 suicides reported in Philadelphia in 1955 is not substantially lower than the 176 automobile fatalities in the same period. The importance is not lessened by the fact that there has been a downward trend in suicide since 1900, when the rate of suicide in Philadelphia was 11.3 per 100,000. In 1955 it was 7.2 per 100,000. In general, the 1900-55 trend in Philadelphia parallels that for the United States during the same timespan.

In cooperation with the office of the medical examiner, the division of mental health of the Philadelphia Department of Public Health conducted a study of suicides that occurred in Philadelphia during the 5-year period 1951-55. The purposes of the study were (a) to learn more about the characteristics of individuals who commit suicide, (b) to determine what data should be gathered routinely to obtain a better understanding of the suicide, and (c) to determine ways in which a public health agency might be instrumental in the prevention of suicide.

Data on the suicides were obtained from the records in the office of the medical examiner. The records included information obtained by police who questioned immediate members of

the family, relatives, neighbors, landlords, and occasionally the family doctor at the time of the suicide. Additional facts had been obtained from the person who identified the body at the morgue. When members of the immediate family were too upset to perform this task, a more distant relative or friend less emotionally involved was substituted. In some cases information had been obtained at a formal inquest. Since the data were gathered from many different sources, it is understandable why the records showed considerable variation in the amount of information. When the suicide was a single person without relatives the information was sketchy.

Very little knowledge of the dynamics in the suicide was obtainable from the records, but some inferences about contributory factors and motivation can be drawn. Extreme caution, however, should be exercised in the interpretation of such data because the information may be unreliable and because factors found to be associated with suicide may not be causally connected.

Classification of Suicides

In Philadelphia, during the 5-year period 1951-55, 742 deaths were classified as suicides by the office of the medical examiner. Of these, 555, or 75 percent, were men and 187, or 25 percent, were women. For whites, the sex ratio was 74 percent men and 26 percent women; for

Dr. Tuckman is chief, section on psychological services, education, and standards, and Miss Lavell is statistician, division of mental health, Department of Public Health, Philadelphia, Pa.

the nonwhites, it was 83 percent men and 17 percent women. Because of the small number, the 12 nonwhite women in this study are not analyzed separately.

Ten percent of the suicides were nonwhite, whereas in the Philadelphia general population aged 15 years and older in 1950, 17 percent were nonwhite. The under-representation of nonwhites among suicides in Philadelphia follows the national pattern (1).

Of the total group, 90 percent were residents of Philadelphia, 9 percent were nonresidents, and about 1 percent were persons whose residence was not determinable.

Using the average estimated health district population during the 1951-55 period as a base, and the residential address of each suicide, rates were calculated for the 10 health districts into which the city is divided. The rates varied from 5.1 to 9.0 per 100,000 population in the various health districts. The highest rate was found for the center-city district, which includes cheap hotels, rooming houses, and "skid row." This finding agrees with those in studies in Chicago (2, 3), in Minneapolis (4), in Seattle (5), and in Providence (6) that suicide is more prevalent in socially disorganized parts of the city.

The data, however, do not support the conclusion of the Minneapolis study that the suicide rate decreases in direct proportion to the number of miles from the center of the city. Actually, it is most difficult to make any generalizations about the distribution of suicides among the health districts because of (a) the lack of accurate population statistics within each health district, (b) the shifting of population from one health district to another, and (c) the number of factors associated with suicide, such as sex, race, age, and marital status. At best the data suggest that the suicide rate varies less than the incidence of mental disorder from one health district to another (7).

Philadelphia's suicide rate of 7.2 is lower than the national rate, which was 10.1 in 1953, the latest year for which statistics are available (1).

The Philadelphia rate is also lower than that of other large cities. For example, in Detroit (8) and in Baltimore (9) the suicide rates in 1955 were 9.8 and 10.0. In Cleveland (10) the

Table 1. Suicide rate¹ per 100,000 population, by age, sex, and race, Philadelphia, 1951-55

15-24.....	2.9	0.7	1.6	1.9	1.8
Total rate ² ..	12.1	4.0	6.6	1.2	7.2

¹ Rates calculated by dividing the total number of suicides in each age group in the 5-year period by the appropriate 1950 census figures multiplied by 5.

² Does not take into account the age-specific rate for each group.

suicide rate for 1953-54 was 12.8. For Cleveland and Baltimore, rates were 14.4 and 11.8 for whites, and 5.7 and 5.3 for nonwhites. The Philadelphia rates for the 1951-55 period were 7.9 for whites and 3.7 for nonwhites.

The lower rates in Philadelphia are difficult to explain. Presumably, the pressures of day-to-day living are no less in Philadelphia. It may be that the differences between the local rate and rates elsewhere in the country are a function of the adequacy of the reporting of suicides in Philadelphia. The medical examiner indicates a possibility that Philadelphia's suicide rate during the years in question may have been spuriously low. With the present improved laboratory facilities and more thorough investigation, the number of deaths classified as suicides may be expected to increase.

Age and Marital Status

The age of the suicides ranged from 15 to 94. There were significant (.01 level) sex and race differences. Among whites, 76 percent of the men were over 45 years of age compared with 63 percent of the women. Among males, the majority of nonwhites were under the age of 45; while the majority of whites were above the age of 45. The median age was 37.5 for white males, 51.1 for white females, and 38.0 for nonwhite males.

Age-specific rates, given in table 1, show a clear tendency for suicide rate to increase with age. There are, however, important differences between whites and nonwhites and between men and women. For whites, the increase of suicide rate with age is clear and is somewhat more pronounced for men than for women. These age differences generally agree with suicide rates for the country as a whole although the national rate for white women most frequently reaches a peak between the ages 55-64 and then decreases (1).

For nonwhite men, the suicide rate does not increase consistently with age. This may be a function of the small number of cases in the sample. It is clear, however, that the rate is highest for nonwhite males in the 65 years of age and older category.

Information on marital status, presented in table 2, was available in nearly all cases. It can be seen that nonwhites had a higher proportion of separated or divorced (23 percent) than the whites (13 percent), fewer widowed (4 percent) than the whites (17 percent), and more single persons (27 percent) than the whites (19 percent). The significant difference in marital status between whites and nonwhites may be, in part, due to differences in age. Since the nonwhites were a younger group, one would expect a lower incidence of widowed among them than among the whites. However, the differences between the two groups in the proportion of separated or divorced cannot be attributed to differences in age.

The marital status of the suicides was different from that of the general population in

Table 2. Marital status of suicides, by race and sex (in percentages), Philadelphia, 1951-55

Marital status	White		Nonwhite		Total group (N=742)
	Males (N=496)	Fe- males (N=175)	Males (N=59)	Fe- males (N=12)	
Single.....	20	17	27	25	20
Married.....	49	47	42	67	48
Widowed.....	16	22	3	8	16
Divorced or sep- arated.....	14	13	27	0	14
Not stated.....	2	1	0	0	2

Philadelphia (1950 census). Comparisons were made between the suicides and the general population for those between the ages of 25 and 44 and those 45 years of age and older. No comparisons were made for the group under 25 years of age because there were only 26 suicides in this age category.

Among the suicides, there was a higher incidence of single, widowed, and separated or divorced persons than in the general population. The difference between the suicides and the general population was evident for both men and women and for whites and nonwhites in the two age groups. Of the white men aged 25 to 44, 30 percent of the suicides were single compared with 20 percent of the general population; 23 percent of the suicides were separated or divorced compared with 4 percent of the general population. For white women and nonwhite men, the differences between the suicides and the general population were similar.

For the age group 45 and over, the differences between the suicides and the general population were less marked with respect to single, and separated and divorced persons, but were in the same direction. As may be expected, a larger proportion of people in this age category were widowed than in younger age groups. For white men and women, but not for nonwhite men, the incidence of widowed was greater for the suicides than for the general population.

Nativity and Employment

Data on nativity indicated that 25 percent of the entire group was foreign born: 7 percent of the nonwhites and 27 percent of the whites. This is considerably higher than the 1950 census figures for Philadelphia, which show only 11 percent foreign born. This difference is more apparent than real and is due to the higher incidence of older people among the suicides than in the general population. When corrections are made for age, the difference between the incidence of foreign born among the suicides and in the general population disappears (table 3).

Data with respect to employment, physical and mental health, medical supervision, history of alcoholism, history of previous attempts or

¹ Excluding housewives and students.

threats, and reported causes, are given for the total group only. Because of the high proportion of cases in which no information was available for these factors, it was not possible to make valid comparisons by race and sex.

Twenty-six percent of the suicides (table 4) were reported to have been unemployed. In half of the unemployed cases, poor physical or mental health was given as the reason for unemployment; in only 3 percent of the cases, seasonal opportunities for work or poor performances on the job were given as reasons, and in the balance of the cases the reason was not stated.

A breakdown by age groups shows very little variation in the percentage of individuals unemployed. The percentages vary from 23 percent of those in the age group 25-44 years to 28 percent of those in the age group 45-64 years. Of those in the 65 and older age category, 23 percent were reported to have been unemployed

and 39 percent retired. For those below the age of 65, the incidence of unemployment is considerably greater than that found in the general population of Philadelphia, and even this is an underestimation since no information was available on employment for about 30 percent of the cases. For those 65 and older, the percentage unemployed or retired is about the same as in the general population in this age category, but information was lacking in 23 percent of these cases.

Physical and Mental Health

Reports of physical health (table 5) had been obtained from a number of different sources, usually from immediate members of the family and other relatives, from friends and neighbors, and occasionally from the family physician. Of the entire group 43 percent were reported to have been in poor health. Good health was reported in only 8 percent of the cases. In 48 percent of the cases no information was available about health status.

Information varied regarding mental illness (table 6). In some cases, the record referred to the fact that the deceased had been suffering from a nervous or mental condition without specifying symptoms. In others a nervous or mental condition was mentioned, together with specific symptoms indicating disturbance in mood, feelings, or behavior. These were primarily described as depressed states, but also as morose, brooding, agitated, upset, worried, confused, queer, acting odd, or remote. In still others the record made no mention of nervous or mental condition but did contain a de-

Mood or behavioral symptoms---	39	29	24	17	35
Not stated-----	30	13	57	50	28

scription of mood, feelings, or behavior. For two-thirds of those suffering from a nervous or mental condition, but for only 3 percent of those with disturbances of mood and/or behavior, a history of nervous or mental condition was also reported.

Of the total group, 10 percent were reported to have had a history of alcoholism. This incidence may be an underestimation since information was not available for 90 percent of the cases. Nevertheless, the incidence of alcoholism among the suicides is considerably greater than that found among the general population, which has been calculated to be 4 percent by the alcoholism unit of Philadelphia General Hospital on the basis of the Jellinek formula.

Receiving Medical Care

In the case of persons who had been under medical care (table 7), the majority of the records gave the name of the physician and usually indicated whether the suicide had been under general medical supervision or under psychiatric care. When there was any doubt, the name of the physician was checked in the county medical society directory. In the other cases, the record merely stated that the deceased had been going to a doctor. In these cases it was not possible to determine the kind of medical care the deceased had received. As would be expected, there was a higher proportion under medical care (77 percent) among those for whom poor physical or mental health was reported.

Of the entire group, 13 percent were reported to have threatened suicide and an additional 9 percent had made one or more attempts. For 3 percent of the cases both previous attempts and threats were reported. Twenty-five percent incidence of either threats or attempts is probably an underestimation, since three-fourths of the records had no information on this point and in some cases threats were implied: "said he would be better off dead," "several times had said she wanted to die," "told wife he had nothing to live for and would be better off dead."

Causes of Suicide

The reported causes for the suicide, or unusual circumstances preceding the death, varied considerably. The causes, and the percent reporting these causes, are presented in table 8.

It is interesting to note that, although two-fifths of the suicides had been reported by relatives and friends to have been in poor physical health, it was given as the cause for suicide by only 18 percent. A similar discrepancy exists for mental disorders. However, it is possible that mental disorders may have been implicit in reasons classified under other categories: disturbed over the death of a relative, depressed, or very much upset when the spouse left him.

Although it is not valid to treat the data statistically because no information is available in nearly half of the cases, the findings suggest that age may be a factor in the causes or un-

¹ In about 5 percent of the suicides, more than one reason was given.

usual circumstances preceding the suicide. For those 45 years and older physical illness was reported as the cause in 25 percent of the cases compared with 3 percent for those under 45; while mental illness was mentioned as the cause in 9 percent of those 45 and older compared with 19 percent of those under 45. Disturbed family relationships were given as the cause for 13 percent of those under 45 compared with 2 percent of those 45 and older. Violence also seemed to be operating more in the younger group (10 percent compared with 2 percent of those 45 and older).

Method of Suicide

The method of suicide most frequently used was hanging, usually by rope (table 9). Firearms was second, and poison was third. Poisons included household drugs and chemicals such as barbiturates, aspirin, and morphine, and lye, ammonia, phenol, turpentine, and arsenic.

There was a significant sex difference with respect to the methods employed. Women were more likely to use poison and gas and less likely to use firearms than men. No significant race differences were found in method of suicide but age was a factor for men. Forty-two percent

of the men aged 45 and older used hanging compared with 32 percent of those under 45; while 22 percent of those under 45 used poison and gas compared with 13 percent over 45.

Place of Suicide

The majority of the suicides took place in the home of the deceased (table 10). Twenty percent occurred on the street and in other public places. Women were more likely to commit suicide in their own homes and less likely to do so on the street and other public places. Of those suicides that occurred in the home, the bedroom and cellar were the preferred places. Each of these was chosen in about one-third of the cases. The kitchen and bathroom were each used by about 10 percent of the cases.

Twenty-four percent of the entire group left one or more suicide notes. A comparison of those who left notes with those who did not shows no significant differences with respect to sex, age, race, or marital status.

There was a significant difference, however, in regard to the method of suicide. Poison was used by 18 percent of those who left notes, but by 8 percent of those who did not leave notes. Firearms were used by 29 percent of those who left notes, but by 19 percent of those who did not. By contrast, hanging was the method used by 40 percent of those who did not leave notes, but by 31 percent of those who did.

No relationship was found between suicide

and day of the week, month of the year, day of the lunar month, or season of the year. Certain times of the day are preferred to others, but the findings should be interpreted with considerable caution since information was available for only 38 percent of the cases. Of these, one-fifth occurred between 9 a. m. and 12 noon, one-sixth between noon and 3 p. m., and another one-sixth between 6 a. m. and 9 a. m. Only one-tenth occurred between midnight and 6 in the morning.

Discussion

This study, like other epidemiological studies of suicide, is limited because of the inadequacies of medicolegal records. Coroners, of necessity, gather information to establish the cause of death rather than to understand the suicide. If more significant insights and knowledge about suicide are to be developed, systematic information needs to be gathered at the time of death. Such information about the suicide should include his developmental background, extent of education, stability of employment, income, health, history of previous psychiatric hospitalization including diagnosis of mental disorder, interpersonal relationships, pattern of adjustment, temperament, interests, stress situations, and whatever other factors that may be deemed important. Such information should

be obtained not only from members of the family, relatives, and friends but also from more objective collateral sources, such as the family doctor and employer, and through search of court, hospital, and social agency records.

The important finding of this study was that the majority of the suicides had been under medical supervision prior to their death, usually by the family doctor. This suggests that the family doctor is in a key position to recognize psychiatric problems in his patients at the earliest possible time and to refer them to appropriate psychiatric resources for special care and treatment. It would be helpful if material on the problem of suicide, with emphasis on methods of detecting individuals with suicidal tendencies, were introduced in the medical school curriculum.

Durations of Illness Among Personnel of the Air Force

HENRIK M. C. LUYKX, D.Sc., and BETTY L. MURRAY, B.A.

MILITARY medical records maintained for the care of the patient are a unique source of data relative to durations of illness. In the Armed Forces, excusal from duty because of illness and subsequent return to duty require the approval of a physician and the preparation of a medical record. Each record shows the diagnosis made by the physician and the total time lost from duty, whether the person was treated in a hospital or in an infirmary, and whether he was in quarters or on sick leave. These data, therefore, are more extensive than those in which only the hospital phase of an illness is recorded, and at the same time they are more reliable than those in which an individual reports his own illness.

A medical record is prepared for each admission, which constitutes enrolling as a patient, a military person whose treatment requires that he be excused from duty beyond midnight of the day on which he reported for treatment. The day of admission is a day of illness; the day of discharge is a day of duty. By definition, therefore, a minimum of 1 day is counted for each admission. Convalescent leave is included in time lost for those patients who must return from such leave for further care and treatment. Convalescent leave granted patients who will return to duty upon expiration of such leave is not included.

The duration of illness, for purposes of this

discussion, refers to total time in an excused-from-duty status during one continuous episode of illness. Included in this study are only those cases returned to duty in 1954, regardless of when admitted. Excluded are fatal cases and those terminated by separation from the service for physical disability. (Return to duty is effected for 98 percent of the patients admitted.)

Table 1 shows selected measures related to the distribution of days lost by 24,508 cases of illness. The mean duration per illness was 12 days. This measure is, of course, influenced by the prolonged duration of relatively few cases. The fact that 75 percent of the cases returned to duty within 10 days (conversely, 25 percent remained 10 days or longer) shows that most Air Force illnesses are of a very short duration. This is to be expected since illnesses of a chronic or prolonged nature are likely to result in disability separation, infrequent in the Air Force population, and not included in this study.

Illnesses of a minor nature may be recorded as excused-from-duty cases for some military persons because domiciliary care (provision of meals in barracks) is normally not available. Also, the same individual may be included more than once either for separate initial occurrences of a given condition or for a recurrent attack of the same condition. A balancing factor, however, is that short-term illnesses treated on an outpatient basis are not included in this study.

Time lost because of a given condition can be discussed adequately only when that condi-

The authors are with the Biometrics Division of the Office of the Surgeon General of the Air Force, where Dr. Luykx is chief of the Division and Miss Murray, analytical statistician.

tion is reported as the sole cause of admission. A single diagnosis is rendered for most illnesses (90 percent) reported among Air Force personnel. Durations of illnesses for multiple diagnosis cases are difficult to interpret because of the different accompanying diagnosis which may or may not prolong the time assigned to the primary cause of illness. Consequently, consideration is focused here on those cases in

which only one diagnosis was reported and which occurred in large enough numbers for meaningful analysis.

Table 2 and figures 1 through 14 pertain to single diagnosis illnesses which resulted in return to duty in 1954. In comparing the shapes of these distributions, it should be observed that two different scales have been used along the abscissa—a 1-day interval or a 10-day interval,

Table 1. Duration of illness among patients returned to duty, U. S. Air Force, 1954

Cases	Number of illnesses ¹	Mean days lost	Range of reliability of mean days lost ²	Day after admission on which specified percentage of cases remained

SOURCE: DD Form 481; DA Form 8-24; NAVMED-F Card.

NOTE: Numbers in parentheses after diagnoses are from the International Lists (sixth revision) with U. S. Air Force expansion.

Durations of illness among Air Force personnel in 1954 showing, of those who subsequently returned to duty, the percent of patients remaining on specified day after admission.

for convenience in presentation. The selected diagnostic conditions have been arrayed in table 2 in order of magnitude of median duration; the graphs, however, have been grouped according to the scale of the abscissa, for easier comparison.

The mean duration, even though influenced by extreme values, has its use as a descriptive parameter. For example, to compute total days lost or accumulated patient loads, for a given diagnosis or for a group of conditions, their mean durations must be known. On the other

hand, percentiles often provide more meaningful measures of a distribution of durations. The most commonly used percentile in vital statistics is the median (50 percent mark). This measure indicates the "middle" duration value. Furthermore, position of this measure in relation to the mean indicates the direction of skewness in an asymmetrical frequency distribution. Frequency distributions according to days lost are not plotted here. The graphs shown are inverse cumulative distributions, thus constituting "cases remaining" curves.

Durations of illness among Air Force personnel in 1954 showing, of those who subsequently returned to duty, the percent of patients remaining on specified day after admission.

Most of the distributions of the illnesses in this study are highly skewed to the right (or even J-shaped). In all instances the mean duration is greater than the median duration. Although any point or points on the percentile scale may be selected for the purpose at hand, the 25 percent and 10 percent marks have been chosen as additional informative measures because of common usage. They represent the number of days of illness elapsed before 75 percent and 90 percent of the cases, respectively, were returned to duty.

Table 2 and the 14 charts show, for each diagnosis, the number of illnesses observed, the mean duration, and the proportion of admissions remaining, by days after admission, with notation of the three percentile points mentioned. Any point on a particular curve indicates the elapsed days of illness (bottom scale) before a given proportion of the cases was returned to duty (complement of the scale at the left). Also, the range of days lost may generally be read directly from the horizontal scale, and, in addition, the modal day of discharge

(the duration most frequently encountered) is at the point showing the steepest drop of the curve.

Noting, for specific illnesses, the difference between the mean and the median gives a measure of the skewness of the distribution. Since skewness is almost invariably to the right, the greatest asymmetry occurs for those illnesses having some unusually prolonged cases. The reason for such skewness is the same as that for a greater range in the distribution, namely that certain diagnostic entities include a large variety of cases with heterogeneous characteristics, as opposed to other diagnoses which include a more homogeneous group of cases. The latter show a smaller range of durations and at the same time greater symmetry in the distribution.

For example, cases of acute uncomplicated appendicitis (fig. 4) of longer than 20 days'

duration were largely accounted for by persons discharged from the hospital who were required to return there at the end of convalescent leave. The type of operation or surgical procedure (not tabulated from these records) in treatment of pilonidal cysts (fig. 12) and duodenal ulcers (fig. 13) has a direct bearing on the duration of illness. The nature of a fracture (figs. 9 and 11) strongly affects the duration; in one case, a compound, comminuted fracture of the radius and ulna with nerve involvement lost 318 days. Other diseases such as the common cold (fig. 1) and streptococcal sore throat (fig. 2), showing a smaller spread of the distribution of durations and concurrent symmetry, suggest a greater homogeneity of characteristics. The means and medians here have approximately the same value.

CDC Laboratory Refresher Training Courses

Refresher training in laboratory methods of diagnoses will be offered at the Communicable Disease Center, Chamblee, Ga., during the period September 1958 through April 1959. Two courses in the following schedule will be presented in two parts, and three will be repeated.

Parasitic diseases:

Part 1. Intestinal parasites. Sept. 15-Oct. 10.

Part 2. Blood parasites. Oct. 13-31.

Rabies. Oct. 6-10; Jan. 12-16.

Viral and rickettsial diseases. Oct. 13-24; Mar. 9-20.

Tuberculosis. Oct. 20-31; Jan. 26-Feb. 6.

Medical mycology: Cutaneous, subcutaneous, and systemic fungi. Jan. 5-30.

Study of pulmonary mycoses. Feb. 9-20.

Veterinary mycology. Mar. 2-6.

Bacterial diseases:

Part 1. General bacteriology. Mar. 2-13.

Part 2. General bacteriology. Mar. 16-27.

Serologic methods in microbiology. Mar. 16-Apr. 3.

Bacterial diseases: Enteric bacteriology. Mar. 30-Apr. 10.

Courses in the following will be offered by special appointment only:

Laboratory methods in the diagnosis of malaria.

Special training in virus techniques.

Typing of *Corynebacterium diphtheriae*.

Special problems in enteric bacteriology.

Phage typing of *Salmonella typhosa*.

Laboratory methods in the diagnosis of leptospirosis.

Serologic differentiation of streptococci.

Bacteriophage typing of staphylococci.

Information and application forms should be requested from the Laboratory Branch, Communicable Disease Center, Public Health Service, P. O. Box 185, Chamblee, Ga.

Commissioned Officer

STUDENT TRAINING AND EXTERN PROGRAM

WILLIAM L. ROSS, M.D.

DURING the 1957 summer months, 120 students from 67 approved professional schools of medicine, dentistry, engineering, and science spent their vacations as Public Health Service Reserve Officers on active duty under the Commissioned Officer Student Training and Extern Program, a career development program known as COSTEP.

COSTEP offers second-year and third-year medical, dental, and engineering students, and science students at the graduate level, on-the-job training in Public Health Service assignments commensurate with their education. These young men and women are thus able to further their professional knowledge and gain experience while earning a salary during breaks in the academic year.

A program must have a purpose, and COSTEP has four:

1. To interest promising students in careers in the Public Health Service.
2. To assist students in furthering their professional knowledge while earning a salary.
3. To give students an opportunity to learn about the functions of governmental health agencies at the National, State, and local levels.
4. To provide the Service with competent personnel during vacation periods.

Last summer's group of 120 students was the largest in the training program's brief history and the first group to participate in the program since it went on a 12-month schedule. The Service has been employing students during the summer months since 1948, when 49 medical students were appointed Reserve Officers in the

Service's Commissioned Corps and called to active duty during school vacations. The commissions were terminated, however, when the students returned to school in the fall. This procedure was repeated in 1949 and 1950.

During the 1951-54 period, dental, engineering, and graduate science students, in addition to medical students, were employed during the summer months under the civil service system. In 1955, students accepted for the Summer Student Program—as it was then known—were appointed to the Commissioned Reserve (the inactive duty reserve component of the Commissioned Corps) and called to active duty when the spring semester ended.

Last year, the program was officially designated as COSTEP, and on July 1, 1957, went on a 12-month basis. This permits students attending schools on the quarter system, with vacations at times other than the summer months, to receive Service assignments during their free periods. As an added inducement, students still in school who have satisfactorily completed a COSTEP assignment are eligible to apply for reassignment the following year.

Assignments

Research assignments under COSTEP are available at the National Institutes of Health in Bethesda, Md., the Communicable Disease Center in Atlanta, Ga., the Sanitary Engineering Center in Cincinnati, Ohio, or in Public Health

Dr. Ross is chief, Recruitment Branch, Division of Personnel, Public Health Service.

Service field activities elsewhere in the country.

Clinical assignments are available in several of the Service's 16 general and specialty hospitals and many of its 55 hospitals maintained for American Indians and Alaska natives.

Students interested in preventive medicine may be assigned to a wide variety of public health programs in many parts of the country. They participate in communicable disease control, sanitary engineering activities, general epidemiology, accident prevention, air pollution control, chronic disease control, occupational health programs, tuberculosis control, venereal disease control, and other related activities.

Second-year students, as a rule, are assigned to research activities. Third-year medical and dental students are usually given preference for clinical clerkships or preventive medicine assignments, but are not excluded from research work. Assignments to clinical clerkships in Alaska are given only to students who are able to serve at least 90 days on active duty.

By category, assignments are generally as follows:

Medical students are assigned to the Service's general and specialty hospitals (up to 1,250-bed capacity) and to its Indian hospitals in the United States and Alaska. They may engage in employee health programs or become research assistants in preventive medicine activities. Some are assigned to mental health studies, and others become research assistants in pharmacology, biochemistry, psychology, metabolic studies, neuropsychology, neurochemistry, and related fields of medical-biological research.

Dental students perform essential duties as research assistants in genetics, biochemistry, and bacteriology. They serve in the dental clinics of the Service's general and specialty hospitals and Indian hospitals. They assist regional dental consultants, work on fluoride analysis, and do field X-ray work.

Engineering students are employed in water pollution control programs, radiological health research, and field engineering for water and sewerage facilities on Indian reservations. Engineering students also work on field survey teams and assist in planning and engineering construction, and in air-conditioning design, construction, and maintenance. Assignments

are also made in insectborne and rodentborne disease control activities.

Science students are offered a variety of assignments. These include cell production and tissue culture, chemistry laboratory work, medical entomology, rabies or psittacosis studies, biological control of mosquitoes, animal psychology, sociology and anthropology, psychiatric aide assistants, social psychology aides, and mental health surveys.

Last summer, one medical student served as assistant to the anesthesiologists in the Clinical Center, National Institutes of Health. Five medical and four dental students took medical histories, performed physical examinations, and conducted hematological studies among 5,000 inhabitants of an in-married population group in an intensive genetic field study of the prevalence of hereditary disease. A science student interested in immunology received instruction in the testing of diagnostic reagents and blood-banking procedures. A psychology student participated in studies of the treatment of children with primary behavioral disturbances.

One of the engineering students reviewed construction plans of oceangoing vessels to determine if they conformed to Public Health Service sanitation standards for water supply and distribution, food preparation, storage, and serving areas, and ratproofing. Other engineering students assisted Service engineers in survey work for water and sewerage improvements on an Indian reservation in the southwest.

Requirements and Remuneration

To be eligible for the Commissioned Officer Student Training and Extern Program, a student must:

1. Be a United States citizen.
2. Be physically qualified for appointment as a Public Health Service Reserve Officer.
3. Have completed at least 2 years of approved professional schooling by the end of the current academic year or, in the case of science students, be at the graduate school level.
4. Submit official transcripts covering undergraduate study.
5. Be recommended by a dean or department head.

Dental student (left) watches trial of a new drill on a hamster at the National Institute of Dental Research.

Students who are commissioned in the Public Health Service and called to active duty under COSTEP receive the pay and allowances of a junior assistant sanitarian, the Service officer grade equivalent to Army 2d lieutenant and Navy ensign. In addition, they are reimbursed for travel from the points at which they receive their calls to active duty to their assignments, and back to the points of origin. The monthly pay and allowances for a junior assistant sanitarian with less than 2 years cumulative service are:

	With depend- ents	Without depend- ents
Base pay.....	\$222 30	\$222. 30
Quarters.....	85 50	68 40
Subsistence.....	47 88	17. 88
Total.....	\$355 68	\$338 58

The Federal income tax, computed on base pay only, is withheld from each month's pay. Previous active and inactive duty with the Armed Forces, the Public Health Service, or the Coast Guard is counted toward longevity for pay purposes.

Students selected for COSTEP are appointed to the Commissioned Reserve and called to active duty for 60 to 90 days. Although leave is accumulated during the tour of duty, COSTEP students are not granted leave except for emergencies. At the end of the duty period, however, they are paid a lump sum for all accumulated leave.

After COSTEP

Students who perform satisfactorily may remain in the Commissioned Reserve pending

completion of professional education. Medical students retain their inactive duty status until they either apply for and are selected for Public Health Service internships or until they complete their intern training outside the Service. Those interning outside the Service, who have military obligations, are called to active duty at the completion of their internships or their commissions are terminated.

Dental students, at the completion of their professional education, may apply for either a Service dental internship or active duty as a staff dental officer.

Draft-eligible students who have satisfactorily completed COSTEP assignments may retain their reserve commissions until they receive their appropriate medical, dental, engineering, or science degrees. Once the degree is earned, the student's commission is terminated unless he applies for and receives an active duty assignment in the Public Health Service in order to fulfill Selective Service obligations. Engineer and science students who have satisfactorily completed a COSTEP assignment, and are still in school, are eligible to apply again for employment under the program.

Because the Commissioned Corps is one of the uniformed services of our country, the serving of specified amounts of time (up to 2 years) in the Corps satisfies military obligations under the Universal Military Training and Service Act. Service under COSTEP or as a Public Health Service intern, however, is not counted toward the satisfaction of military obligations.

Applications and Reserve Commissions

Students interested in COSTEP assignments during the summer months must submit their applications each year before February 1 to the Surgeon General, U. S. Public Health Service (P), Washington 25, D. C. Applications for assignment at other times of the year must be submitted at least 120 days beforehand.

It is not necessary for medical students to apply for COSTEP assignments in order to receive appointment to the Commissioned Reserve. Medical students interested in intern-

ships, active duty to fulfill Selective Service obligations, or careers in the Public Health Service may apply for appointment to the Commissioned Reserve any time after completing their first year of medical school. Dental, engineering, and science students, however, can receive reserve appointments only through COSTEP. Medical or dental students who have satisfactorily completed a Public Health Service internship are continued on active duty unless they request termination of their commissions. The Service imposes no mandatory period of duty upon its Commissioned Reserve officers.

COSTEP Survey

A survey of students who were employed under COSTEP during the summer months of 1957 disclosed that they found their assignments interesting and professionally valuable. Eighty-six percent indicated that they planned to apply for active duty in the Commissioned Corps after graduation. More than half of the group of 120—nearly all of whom are eligible for participation in 1958—are planning to apply again for COSTEP assignments. Most of the group felt that their assignments provided professional experience that would be helpful in school. Fifty-nine percent reported that they found their work "very interesting" and 71 percent found their professional education useful in their COSTEP assignments.

Features that many students named as advantages of the program were professional experience; working with congenial people; opportunity to learn new developments and exercise initiative; the ability, helpfulness, and interest of supervisors; and the opportunity to work with patients.

When asked what special efforts were made to aid in their professional development, the students mentioned the opportunity to attend hospital rounds outside their departments, outside reading and reporting to a group, attending clinical and pathology conferences, seminars, time for literature research, and the availability of experienced professional personnel to answer questions and discuss work.

Coxsackie virus group B, type 5, widely distributed in the midwest during the summer of 1956, was highly prevalent in Iowa, with lower frequencies observed in Kansas, Missouri, and Nebraska. Concurrently in Iowa, the incidence of poliovirus infection was found to be extremely low.

Infections With Coxsackie Virus B5 in Six Midwestern States

TOM D. Y. CHIN, M.D., JOHN C. GREENE, D.M.D., and HERBERT A. WENNER, M.D.

THE RECOGNIZED viral agents responsible for the syndrome defined as benign aseptic meningitis include mumps, ECHO (enteric cytopathogenic human orphan), Coxsackie, poliomyelitis, and the arthropod-borne encephalitis viruses. Observations made during the summer and autumn months of 1956 indicated an unusually high incidence of cases of aseptic meningitis in certain midwestern communities. Fecal specimens submitted for poliomyelitis surveillance studies yielded a large number of isolates identified as Coxsackie virus, type B5.

The evidence that the B5 virus was etiologically related to many of the cases observed was reinforced by a singular study of a localized outbreak of aseptic meningitis caused by Coxsackie B5 virus in Cerro Gordo County, Iowa, during the same summer (1). The present report summarizes our experiences encountered with this virus with particular reference to differences in the distribution in the six midwestern States.

Materials and Methods

During the summer and autumn months of 1956, fecal specimens obtained from 694 individuals were studied in connection with the poliomyelitis surveillance program. Of this

number, 365 were obtained from patients believed to have poliomyelitis; the remaining 329 specimens were collected from patients and family contacts during an investigation of an outbreak of aseptic meningitis. These specimens were from residents in the midwestern States of Arkansas, Iowa, Kansas, Missouri, Nebraska, and Oklahoma. In addition to the 694 fecal samples studied in the virus laboratory at the University of Kansas, the distribution study included 664 individual specimens also obtained from poliomyelitis patients, bringing the total of fecal samples to 1,358. The 664 specimens were studied in the State health department laboratories in Kansas and Missouri and in the virus laboratory of the University of Nebraska College of Medicine, results of isolations in these laboratories having been supplied by Dr. Charles A. Hunter, Irma C. Adams, and Helen W. Reihart.

Dr. Chin is assistant chief of the Kansas City Field Station, Communicable Disease Center, Public Health Service, where Dr. Greene serves as dental surgeon on temporary duty. Dr. Wenner is research professor of pediatrics at the University of Kansas Medical Center, Kansas City, Kans. Assisting in the study were Clifton R. Gravelle of the Kansas City Field Station and Vernon E. Scholes of the University of Kansas Medical Center.

completion of professional education. Medical students retain their inactive duty status until they either apply for and are selected for Public Health Service internships or until they complete their intern training outside the Service. Those interning outside the Service, who have military obligations, are called to active duty at the completion of their internships or their commissions are terminated.

Dental students, at the completion of their professional education, may apply for either a Service dental internship or active duty as a staff dental officer.

Draft-eligible students who have satisfactorily completed COSTEP assignments may retain their reserve commissions until they receive their appropriate medical, dental, engineering, or science degrees. Once the degree is earned, the student's commission is terminated unless he applies for and receives an active duty assignment in the Public Health Service in order to fulfill Selective Service obligations. Engineer and science students who have satisfactorily completed a COSTEP assignment, and are still in school, are eligible to apply again for employment under the program.

Because the Commissioned Corps is one of the uniformed services of our country, the serving of specified amounts of time (up to 2 years) in the Corps satisfies military obligations under the Universal Military Training and Service Act. Service under COSTEP or as a Public Health Service intern, however, is not counted toward the satisfaction of military obligations.

Applications and Reserve Commissions

Students interested in COSTEP assignments during the summer months must submit their applications each year before February 1 to the Surgeon General, U. S. Public Health Service (P), Washington 25, D. C. Applications for assignment at other times of the year must be submitted at least 120 days beforehand.

It is not necessary for medical students to apply for COSTEP assignments in order to receive appointment to the Commissioned Reserve. Medical students interested in intern-

ships, active duty to fulfill Selective Service obligations, or careers in the Public Health Service may apply for appointment to the Commissioned Reserve any time after completing their first year of medical school. Dental, engineering, and science students, however, can receive reserve appointments only through COSTEP. Medical or dental students who have satisfactorily completed a Public Health Service internship are continued on active duty unless they request termination of their commissions. The Service imposes no mandatory period of duty upon its Commissioned Reserve officers.

COSTEP Survey

A survey of students who were employed under COSTEP during the summer months of 1957 disclosed that they found their assignments interesting and professionally valuable. Eighty-six percent indicated that they planned to apply for active duty in the Commissioned Corps after graduation. More than half of the group of 120—nearly all of whom are eligible for participation in 1958—are planning to apply again for COSTEP assignments. Most of the group felt that their assignments provided professional experience that would be helpful in school. Fifty-nine percent reported that they found their work "very interesting" and 71 percent found their professional education useful in their COSTEP assignments.

Features that many students named as advantages of the program were professional experience; working with congenial people; opportunity to learn new developments and exercise initiative; the ability, helpfulness, and interest of supervisors; and the opportunity to work with patients.

When asked what special efforts were made to aid in their professional development, the students mentioned the opportunity to attend hospital rounds outside their departments, outside reading and reporting to a group, attending clinical and pathology conferences, seminars, time for literature research, and the availability of experienced professional personnel to answer questions and discuss work.

Table 2. Coxsackie virus B5 isolations from fecal specimens, by county, Iowa, 1956

¹ Comprising 249 patients and 80 well persons.

gitis appeared in epidemic proportions in several localities in Iowa. The occurrence of this illness was first noted in Polk County during early July. In the middle of July similar illnesses were observed in Mason City, the county seat of Cerro Gordo County. Because the clinical features suggested that these illnesses were not caused by polioviruses, a detailed study was made in Cerro Gordo County in order to define the etiology and the clinical and epidemiological characteristics. Etiological studies indicated that these illnesses were caused primarily by Coxsackie virus, type B5.

The frequency with which Coxsackie B5 virus was encountered in different localities in Iowa appears in table 2. In Cerro Gordo County the virus was recovered from 82 of the 135 individuals examined. Of the 82 Coxsackie B5 strains recovered, 61 were isolated from 83 individuals with illness, while 21 were recovered from 52 well individuals, the majority being household contacts. A high frequency of virus recovery was obtained in the counties of Black Hawk, Polk, and Dubuque, whereas lower frequencies were observed in Webster and Calhoun Counties. Although extensive epidemiological investigation was conducted only in Cerro Gordo County, these data seem to indicate that a similar type of illness was also occurring in epidemic proportions in Black Hawk, Polk, and Dubuque counties.

The distribution of Coxsackie B5 viruses isolated from 144 Iowa patients by week of onset of illness appears in figure 2. The major number of isolations were made from patients who

were ill during the months of August and September with the highest frequency occurring during the middle of August. A similar distribution was obtained for patients in Cerro Gordo County alone. In the State as a whole the seasonal distribution of Coxsackie B5 virus corresponded to that observed for poliomyelitis.

The distribution of Coxsackie virus B5 isolated from stool specimens of 329 Iowa residents analyzed according to age and health status is shown in table 3. Approximately 58 percent of the individuals who had an illness manifested as either aseptic meningitis or minor illness yielded the B5 virus, while about 36 percent of those with a history of no illness excreted B5 virus. In both ill and well groups the frequency of excretion was higher among those under 20 years than in those over 20 years of age.

Discussion

The first Coxsackie viruses were recovered by Dalldorf and Sickles in 1947 (5). During the past 10 years these viruses, now constituting a family of 24 members, have been encountered with an increasing frequency in association with a variety of illnesses. As a result of recent wide application of tissue culture techniques, Coxsackie viruses of types A9, B1, B2, B3, and B4 have been commonly recovered from patients with aseptic meningitis, pleurodynia, and myalgia, and occasionally

Figure 2. Coxsackie virus B5 isolations from feces of patients, by week of onset, 1956.

Stool specimens were collected by practicing physicians or by the staff members in local hospitals. Usually single specimens were obtained. Fecal specimens were collected from household contacts only in connection with special investigation of localized outbreaks. The specimens were mailed unfrozen to the laboratory, where they were stored at -20°C . and held at this temperature until used.

The methods used for preparation of stools and for virus isolation and identification were those described by Wenner and Miller (2). Roller tube cultures of trypsin-dispersed monkey kidney cells prepared according to the methods described by Youngner (3) were routinely employed. Each specimen was tested in three culture tubes, using 0.1 ml. of stool extract per tube. The cultures were maintained for a 7-day period. Fluids of those cultures showing cytopathic changes were harvested for identification, using initially type-specific hyperimmune poliomyelitis antisera (4). When the harvested fluid was not neutralized by each of the typing serums or by a combination of the serums, further identification was carried out with Cocksackie antisera types 99, B1, B2, B3, B4, and B5, and with 14 types of ECHO antisera. Neutralization was considered to have occurred if the culture tubes containing the virus-serum mixtures showed no cytopathic changes while cytolysis was present in the virus control tubes, and if this effect persisted for at least 2 additional days.

Virus Distribution in the Six States

Data on the frequency with which polioviruses and Cocksackie viruses were encountered in the specimens from 1,358 individuals submitted for study are summarized in table 1. The geographic distribution of individuals providing Cocksackie B5 viruses appears in figure 1.

The B5 virus was recovered from the stools of 270 individuals, and polioviruses, predominantly type 1, were recovered from the stools of 275. A stool from one individual yielded both poliovirus and Cocksackie B5 virus. Patients from Iowa provided a larger number of B5 viruses than those from the other five States studied. The recovery rates among 329 fecal

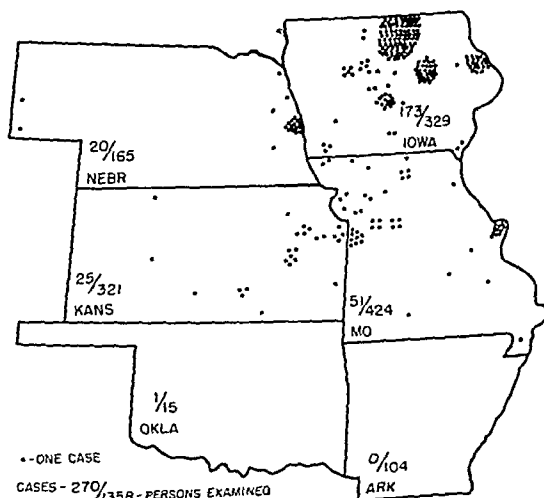

Table 1. Cocksackie virus B5 and poliovirus isolations from fecal specimens, by State, 1956

State	Number of persons	Cocksackie virus B5		Polioviruses	
		Number	Percent	Number	Percent
Arkansas.....	104	0	0.0	37	35.6
Iowa.....	329	173	52.6	8	2.4
Kansas.....	321	25	7.8	56	17.4
Missouri.....	424	51	12.0	141	33.2
Nebraska.....	165	20	12.1	29	17.6
Oklahoma.....	15	1	6.7	4	26.7
Total.....	1,358	270	19.9	275	20.2

samples from Iowa were about 53 percent for Cocksackie virus and 2.4 percent for polioviruses. In Kansas, Missouri, and Nebraska, the recovery rate for Cocksackie virus was approximately 11 percent and for polioviruses approximately 25 percent. In contrast with the experience in Iowa, Cocksackie B5 virus was not detected in fecal specimens from 104 individuals in Arkansas, although polioviruses were recovered from approximately one-third. The number of specimens originating in Oklahoma was too small for reliable comparison; nevertheless, one strain of Cocksackie B5 virus was recovered in the 15 fecal samples examined.

During the summer of 1956 aseptic menin-

Figure 1. Distribution of Cocksackie virus B5 in six midwestern States, 1956.

the introduction and continued use of the Salk vaccine.

As for age distribution of those infected with the B5 virus, rates of infection were approximately the same for persons under 20 years of age in both ill and well categories. These rates were significantly higher than those of the older group. This difference in age-specific incidence indicates that the older population was more resistant to Cocksackie B5 virus infection, possibly because of infection some years ago with an agent similar or antigenically related to Cocksackie virus B5. The uniform infection rates among persons in younger age groups further suggest that Cocksackie virus B5 probably had not been active in Iowa during recent years.

Summary

During the summer of 1956 Cocksackie virus was found widely distributed in several mid-western States. Infections due to this virus appeared in epidemic proportions in several localities in Iowa; about 53 percent of the stools examined yielded Cocksackie virus B5, while about 2 percent contained polioviruses. The frequency of isolating the B5 virus in Kansas, Missouri, and Nebraska ranged from 8 to 12 percent. In Arkansas, none of 104 individuals examined yielded Cocksackie viruses, while 36 percent had polioviruses. One strain of Cocksackie virus B5 was isolated from 15 individuals examined in Oklahoma.

Studies in Iowa also showed that the seasonal incidence of Cocksackie B5 infection was similar to that of poliomyelitis. The frequency of detecting this virus was higher among persons under 20 years than in those over 20 years of age.

from those with myocarditis. Until the summer of 1956, the type B5 Coxsackie virus, which was first isolated by Steigman in 1952 (6), had been found only occasionally. The data reported here and those recently reported by Syverton and associates (7) represent the first recognition of a widespread occurrence of this virus in association with human illness.

The variation in the geographic distribution of this virus in the six midwestern States is worthy of comment. Obviously, this virus appeared in epidemic proportions in Iowa. Of the 329 Iowans studied, about 53 percent yielded the B5 virus, while only about 2 percent yielded polioviruses. In contrast, none of the stools from 104 patients in Arkansas yielded Coxsackie viruses, while 36 percent were shown to contain polioviruses. In Kansas and Missouri, polioviruses were more commonly encountered than the B5 virus, while both viruses appeared in about equal frequency in Nebraska. The number of specimens obtained from Oklahoma was too small for reliable comparison.

Suggested as a factor producing variations in geographic distribution of Coxsackie B5 virus is the apparent incompatibility of Coxsackie B and poliovirus infections. In the laboratory Coxsackie B infections appear to exert an interfering effect on poliovirus infections in mice (8, 9) as well as in tissue cultures (10). Field observations also suggest that such interference may occur in man, and the evidence in favor of this hypothesis has recently been reviewed by Dalldorf (11). A high incidence of Coxsackie B infection is usually accompanied by a low incidence of polio-

myelitis, and furthermore, when Coxsackie B and poliovirus infections occur simultaneously in the same area, the peak incidence of Coxsackie infection usually precedes that of poliovirus infection by 1 or 2 months (12).

Besides the possibility that it represents the effect of interference, the high incidence of Coxsackie B5 virus infection associated with a low incidence of poliovirus infection can also be explained by certain ecologic and immunological factors. They might be the impact of past infections, resistance acquired through vaccinations, balance of immune and susceptible persons, and the introduction of a new virus into a population. The observations made in Mason City (1) as well as those reported here for other parts of Iowa indicate that the residents of that State were highly susceptible to Coxsackie B5 virus infection. Hence, introduction of this virus into the State, under favorable conditions, would result in an epidemic. On the other hand, the population of Iowa was relatively resistant to poliomyelitis as a result of past infections, and their immune status had been reinforced by the recent use of the Salk vaccine.

A review of the Iowa data for the past 3 years shows that when the Salk vaccine was first introduced in 1954 there were 1,445 reported cases of poliomyelitis, 525 (36.3 percent) of which were paralytic. In 1955, the number dropped to 556, with 114, or 20.5 percent, paralytic. During the following year there were 580 cases, but only about 8 percent were paralytic. This decline in incidence and in the ratio of paralytic cases coincides with

the introduction and continued use of the Salk vaccine.

As for age distribution of those infected with the B5 virus, rates of infection were approximately the same for persons under 20 years of age in both ill and well categories. These rates were significantly higher than those of the older group. This difference in age-specific incidence indicates that the older population was more resistant to Coxsackie B5 virus infection, possibly because of infection some years ago with an agent similar or antigenically related to Coxsackie virus B5. The uniform infection rates among persons in younger age groups further suggest that Coxsackie virus B5 probably had not been active in Iowa during recent years.

Summary

During the summer of 1956 Coxsackie virus was found widely distributed in several mid-western States. Infections due to this virus appeared in epidemic proportions in several localities in Iowa; about 53 percent of the stools examined yielded Coxsackie virus B5, while about 2 percent contained polioviruses. A Manual on Recordkeeping and Statistical Reporting for Mental Health Clinics

*PHS Publication No. 539. 1957.
72 pages; illustrated. 45 cents.*

Methods and record forms evolved by clinics, States, and the National Institute of Mental Health, Public Health Service, for routine recording, collection, and compilation of selected items of information about patients and the services they receive in outpatient psychiatric clinics are presented in this manual.

The procedures are designed to provide the minimum of essential data included in the Annual Statistical Report of Outpatient Psychiatric Clinics, which is the report used in a national reporting program developed by the National Institute of Mental Health. The suggested procedures also take into account some variation in need by clinics and States for data beyond those collected nationally as well as differences in availability of clerical and statistical personnel and equipment.

Evaluation of Obstetric and Related Data Recorded on Vital Records and Hospital Records: District of Columbia, 1952

Vital Statistics—Special Reports. Selected Studies. Vol. 45, No. 13. Nov. 20, 1957. By Ella Oppenheimer, Samuel Schwartz, Alexander L. Russell, Matthew Tayback, and Eleanor P. Hunt. Pages 359-416; tables. 40 cents.

This study concerns the collection, development, and use of medical information reported on birth certificates. A sample group of 1,000

births in the District of Columbia's major hospitals is used to evaluate the accuracy and completeness of reporting such items as birth weight, period of gestation, conditions of pregnancy and labor, and method of delivery. The medical information on the birth certificates is compared with matched hospital record data. The method and the findings are given in detail.

A second phase of the study demonstrates the use of medical information from birth and stillbirth certificates and hospital records in showing significant relationships between obstetric factors and the outcome of pregnancy.

The report concludes with a summary of actions taken in the District of Columbia to develop and improve medical information derived from birth certificates.

Health Statistics From the U. S. National Health Survey

Preliminary report on volume of physician visits, United States, July-September 1957

*PHS Publication No. 584-B1. 1958.
25 pages; tables. 25 cents.*

Preliminary report on volume of dental care, United States, July-September 1957

*PHS Publication No. 584-B2. 1958.
22 pages; tables. 25 cents.*

First and second of a new series (Series B), these reports present data from household interviews conducted by the U. S. Bureau of the Census for the Public Health Service. The first report estimates the number of physician visits per person, by age, sex, and rural-urban residence. It gives the distribution by type of service and by place of visit (home, physician's office, hos-

pital clinic, or other) and shows the time interval since the last physician visit.

The second report estimates the volume of dental visits classified according to sex, age, urban-rural residence, and type of service (fillings, extractions, cleaning teeth, examination, denture work, straightening, gum treatment, and other). It also shows distribution of the population according to interval since last dental visit, by age, sex, and urban-rural residence.

Notes on methods and definitions of terms are given in the appendixes in each publication.

An Outline of Venereal Disease Management

PHS Publication No. 573. Revised 1957. 14 pages. 15 cents.

Information on diagnosis and management of venereal diseases is brought up to date in this revised booklet. Suggested epidemiological techniques and followup procedures are included, as well as detailed schedules of treatment for syphilis, gonorrhea, nonspecific urethritis, saprophytic spirochetal balanitis, chancroid, granuloma inguinale, and lymphogranuloma venereum.

The schedules are based on experiences of a large number of clinics and clinicians, as assembled by the Venereal Disease Branch, Communicable Disease Center, Public Health Service.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared by other Federal agencies.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. More people are attaining advanced age. Will social science help them to enjoy it? What roles are the aged to perform for their satisfaction? And how are cultural values to be adjusted to provide proper appreciation for such roles?

Sociological Aspects of Aging

HOWARD E. JENSEN, Ph.D.

THE biological and sociological problems of aging, although complementary, are quite disparate. Biological research on the progressive changes taking place in the aging organism deals with objective anatomical and physiological phenomena directly measurable by physically standardized instruments. Sociological investigation of the interrelationships of the aging organism and the sociocultural environment, on the other hand, is concerned with covert or subjective attitudes and values that are only indirectly measurable by instruments. These, in turn, involve various culturally conditioned judgments in their construction, and require constant revision and restandardization with advances in theory and changes in cultural value systems, if they are commensurable at all.

Furthermore, as we pass from the biological to the sociological investigation of aging, the locus of research shifts from the more static conditions of the laboratory and clinic to the more dynamic settings of fieldwork where scientific controls are at best crude, and often

impossible. In no field is it more difficult to transmute the particularities of individual case study into the generalities of statistical analysis.

Again, unlike biological systems, human social systems are structured not by the genetically determined reaction patterns of the biological units that compose them, but by behavior patterns invented and acquired in social interaction. These socially derived patterns constitute the systems of cultural values which determine the social structure of human groups. Such structures do not age and die. They either commit suicide by man's inability to devise new patterns capable of dealing with the problems generated from within, or they are murdered by his inability to repel conquest from without. A social system is simply the blueprint according to which interpersonal and social functions have occurred in the past, are occurring in the present, and may be predicted to recur in the future.

Therefore, the aging of an individual, as a sociocultural phenomenon, is defined not by physical deterioration or by time but by the value system of his society. A person is sociologically old when he is so regarded and treated by his socii. The problems of personal and social adjustment confronting the aged are the resultants of the role and status accorded them by the group, the social provisions for their continuing prestige and security, and the opportunities afforded them to achieve these ends by their own initiative.

*Dr. Jensen was chairman of the department of sociology and anthropology, Duke University, Durham, N. C., when his paper, on which this one is based, was delivered before the Duke University Council on Gerontology at a seminar on April 2, 1957. He is now professor emeritus of sociology. The full paper was published in *Proceedings of Seminars, 1956-57*, edited by F. C. Jeffers, A. H. Edens, and E. W. Busse, November 1957.*

There is neither time nor need to survey the widely divergent perspective of aging in various social milieus. Those interested in pursuing this subject further may well begin with Simmons (1) and Eisenstadt (2). Suffice it to say that universally these varying perspectives are the result of the interplay of automatic and impersonal physical, biological, and social forces on the one hand and conscious and purposive personal and social efforts on the other. Sociological interest focuses upon this interplay in all cultures.

The aging populations of all cultures experience similar physiological changes that manifest themselves overtly in deterioration of physical and ultimately of mental capacities. Universal, too, are the probabilities of bereavement by the death of one's mate, especially for women. For the greater longevity of women, insofar as comparative data are available, seems to be a phenomenon common to all cultures.

Changes in physical activities are everywhere precipitated by these overt manifestations. But sociological interest in the problem of aging does not focus, as does the biological interest, upon the objective measurement of these changes. Instead, it focuses upon the investigation of the cultural value systems that define these changes in role and status, and upon the meaning of these changes to the aging persons themselves and to their contemporaries.

Problems of Aging

Sociologically considered, the problem of aging in contemporary western culture is a new phenomenon in human history in at least four ways. Two of these, the increasing number of the aged and the extension of the time during which they enjoy (or suffer) that status, are too well known to require more than passing mention.

Two other circumstances have so completely changed the sociological character of the problem that it is hardly an exaggeration to say that prior to their emergence the problem did not exist. These are the abruptness of the social transition from productivity to retirement and the loss of role and status that accompanies it.

In the simpler cultures, as well as in our own until the last 2 or 3 generations, the gradualness of the physiological changes was paralleled by

a corresponding gradualness in the change of social functions, which permitted a smooth transition and a gradual adjustment to the new functions by both the aged and their younger contemporaries.

Again, in the simpler societies and in traditionally oriented cultures like our own until recently, the aged, as a general rule, usually suffered no such loss of role and depreciation of status as is the fate of the majority in our highly developed technological civilization.

In every society, aging is accompanied by changes in the active roles played by the aged and in the functional categories to which they belong. In the simpler societies and in cultures oriented to tradition, role and status are usually ascribed rather than achieved. That is, the functions to be performed by the person are determined by characteristics over which he has no control, among the more important of which are family lineage, sex, and age. When roles are age-graded the person acquires the status assigned to his role. One knows precisely what changes of role will be expected of him and what rank will be accorded him as he passes from one age grade to another. This transition is so gradual, and the social conditions under which it takes place so stable, as to permit the value systems of the culture to be effectively internalized in the character of the person. Thus, a fair degree of harmony between the expectations of the person and the requirements of the group is maintained.

But in a society based on applied science and technology, both role and status are achieved rather than ascribed. The role is determined by the individual's capacity to perform the functions required, and status by the evaluation placed by the group upon the role performed. In such a society role and status are conjoined. Status is thus linked with the role rather than with the person performing it, so that when the role is no longer performed, the status tends to deteriorate.

Tradition and Status

In societies with ascribed status there are at least six distinct roles ascribed to the aged that give them a recognized and assured social position:

First, the aged are the preservers and disseminators of the knowledge of the group. They are its library as well as its teachers, for the sacred lore is stored only in their memories. As a Yoruba proverb states it, "A man may be born to fortune, but wisdom comes only with length of days."

Second, by virtue of this monopoly the aged hold a strategic position in deciding the policies of the group. The maxim, "Old men for council, young men for war," is practically universal in traditionally oriented societies.

Third, and closely associated with the foregoing, are the rights and privileges associated with parental authority and the ownership and management of family property. These prerogatives may persist long after death through the sacred and binding character often accorded by the culture to the dying wishes of family heads with regard to property and other matters within their jurisdiction.

Fourth, the aged are often the magicians, witch doctors, priests, and seers as well as the sages of the group. This role also frequently survives death through the prevalence of ancestor worship and fear of ghosts.

Fifth, they possess the experience and skill required to supervise the industrial and decorative arts.

All these are roles that require little physical strength or stamina. They can be performed as long as accurate memory, sound judgment, and social skill in managing interpersonal relationships continue. They are also highly honorific roles whose prestige usually outlives the person's capacity to perform them and gives to age as such a respect and dignity that redounds to the benefit of less competent contemporaries.

For the latter there remains a sixth role. The lighter auxiliary tasks of field and herd, of hearth and household fall to their hands. By these activities they release mature adults of both sexes for more strenuous work and so maintain their status as participants in the common life.

Technology and Status

All of these roles have played a significant part in the history of our own culture. Some

of them have been abolished by the processes of social change, and those that survive have been greatly reduced in significance. The monopoly of wisdom and knowledge began to weaken with the invention of writing, and has finally been wiped out by universal mass education. The ceremonial role ceased with the passing of magic and the rise of professionally trained religious leaders. The policy-forming role survives only for the higher professional, administrative, and bureaucratic classes, most notably in politics. Finally, the rise of technology has greatly reduced the role of the handcraftsman and the need for auxiliary services.

Prescribed roles have dwindled as technology has advanced and such functions as remain to the aged are no longer the prerogative of age. In a technological civilization, roles are won in strenuous competition requiring youth and stamina. Status is achieved chiefly through the performance of role, and, for the majority of the aged, status does not long survive its passing.

Older persons of the upper classes of business and professional people who have been successful may continue to be in active demand on a part-time basis or as consultants, and to enjoy an ascribed status after they have relinquished the roles through which status was achieved. But for those of the lower classes, especially the unskilled workers, the loss of their economically productive roles is usually less gradual, less voluntary and reversible, and they enjoy no such halo effects of past achievement. They are suddenly precipitated into a situation where they lose their financial independence, their capacity to make their own decisions, and, what is worse, the esteem of their fellows and their own self-respect.

But new technological changes now in process may have some effect in reversing this trend, as an increasing percentage of the gainfully employed is now being absorbed into professional, technical, clerical, and other more honorific pursuits and a decreasing percentage into the more arduous and unskilled occupations.

For humanistically inclined researchers, the biological objective of gerontology is to make old age attainable; the sociological objective is to make it satisfying. Medical progress has increased the proportion of the aged; technological progress has reduced the proportion of

meaningful roles available to them, and the cultural lag in the social sciences leaves us as yet inadequately equipped to deal with the resultant problems of personal and social adjustment.

For social research, the fundamental problem is to discover and investigate the social—not the physical—barriers that limit the aged in the pursuit of satisfying goals. For applied sociology, the problem is to devise techniques to remove or reduce these barriers, or, at least, to compensate for them. Techniques must also be developed to help aging people to gain insight into and to adjust to the changing biological, social, and cultural conditions that confront them.

Although these social barriers are generally considered to be a product of urbanization and industrialization, both of the latter are the results of technological changes which began to revolutionize urban life in the 19th century and have now been extended to rural life as well. While it is still true that a rural environment is more suited than an urban one for satisfactory living in the older years, technological changes on the farm are also making successful adjustments more difficult there. In fact, in at least one respect the reaction of the aged to role changes may perhaps be less severe in metropolitan than in less highly urbanized areas, because of a greater degree of anonymity and compartmentalization of roles among urban dwellers, and a consequent lessened effect that the reduction in any one role has upon participation in others.

Social Adjustment

The criterion of social adjustment, for the purpose of this discussion, is the degree to which an individual is able to satisfy his personal needs and to accept the role and status accorded him by the value system of his community.

There are two types of adjustments confronting the individual in relation to his social roles: (a) that normally required by the social category to which the individual belongs, and (b) that resulting from a shift in role from one social category to another, which usually aggravates the attendant problems of adjustment.

The two problems are quite distinct. If, in the course of his life, a man remains in the same role, while other roles which were formerly subjectively rated on a parity with or beneath his own increase in prestige, he suffers a reduction in status, notwithstanding the fact that his role may have remained stationary or actually improved. Studies of role and status that do not penetrate beneath the objective facts to the changing evaluation of the culture and the subjective attitudes felt by those who participate in it have little to contribute to our understanding of human relations in general or aging in particular.

Space does not permit a review of the way in which these problems vary with regional, rural, rural nonfarm, suburban, urban, and metropolitan distribution or with position in the class structure, racial and ethnic origins, voluntary and involuntary retirement, financial ability, occupation, education, religious affiliation, family integration, self-identification with aging, and many other sociocultural factors.

Suffice it to say that there has been little investigation of the more fundamental sociological problems of these categories as evaluated by the community or by the aging persons themselves. Such an objective factor as decline in socioeconomic status, for example, is relatively easy to measure. It is valuable so far as it goes, but it is an inadequate index of the sociological problem of aging. It can only be interpreted in the light of the subjective attitudes of satisfaction or dissatisfaction of the person with his new role and status, and of the equally subjective cultural value system that conditions these changes.

As the research of Burgess has disclosed, even so objective a measure as a count of the activities participated in by the aged correlates but moderately with personal adjustment to aging, from which he concludes that "it is just as important, or even more so [to] get at the subjective reactions" and "self-conceptions of older persons" through their introspective reports of their attitudes and states of feeling as it is to study their objective situations (3).

Furthermore, these questions of attitude have as their correlates corresponding questions of value. To what extent, for example, do conceptions of the self as culturally derived affect

the adjustment of the aged? The available data indicate a significantly higher degree of maladjustment among those who identify themselves as old than among those who are in fact 70 or older. It has also been noted that those under 70 who identify themselves as old show a slightly higher ratio of maladjustment than those 70 and over who identify themselves as middle aged. It would seem, then, that although age identification is a factor in maladjustment, the importance of this factor cannot at present be assessed. The degree to which age identification is influenced by psychological factors resulting from such physiological and social changes as loss of mate or loss of role and status due to physical and mental deterioration is unknown. But one thing is certain, under the prevailing value system of our culture, to identify oneself with the aged is to accept a negative social evaluation of the self.

The simplest part of the sociological problem of aging, then, is to ascertain the objectively determinable physical needs of the aged (chiefly economic security, housing and medical care, and recreational and other leisure-time facilities), and to provide for them.

But knowledge about and suitable provision for the less tangible and more subjective socio-cultural needs present far more difficult problems for both social research and social action. Chief among these are needs associated with the more subjective values of religion, emotional security, personal independence, and social status and role. Among these the religious needs should be the easiest both to determine and to satisfy.

Retirement

The needs for independence and for social role and status present far different and more difficult problems. It is in these questions of social role and status that the sociological problems of gerontology chiefly consist.

Preliminary research, for example, indicates that it is involuntary retirement rather than financial ability per se that is associated with initial adverse reaction to retirement (4). Cavan and associates report that, other social categories being equal, old people who have had a hard life keep their faculties much better and

make a more realistic adjustment than those who have had an easier one (5). Nevertheless, voluntary and enforced retirement show a high correlation respectively with positive and negative attitudes toward that status. Voluntary retirement presents few problems of personal maladjustment in making the transition. But most of those forced into involuntary retirement undergo at least temporary maladjustment. Although financial ability or inability to retire seems to make little difference in the immediate adjustment to retirement, the financially able adjust more quickly than those who are compelled to find or to accept new sources of financial support (6a). The burden of retirement therefore rests most heavily on the lower classes, few of whom are able to retire voluntarily. Lack of regular activity is several times as prevalent here as in the middle and upper classes, and most of them desire to return to work. This is confirmed by the tendency of able-bodied retired workers to return to full employment when the opportunity to do so becomes available. Those who are physically unable to continue at their former occupations would rather transfer to less strenuous jobs with less loss of income than retirement would impose, bitterly as they may resent the loss of status involved. Prevailing cultural evaluations make it difficult for the worker to adjust to a lowering of status within the established hierarchy of employment roles.

There is no substitute for gainful employment for this group, both because of economic need and because their limited range of interests provides little motivation to engage in other forms of satisfying and creative activity. Such persons have little to retire to except retirement, owing to the difficulty of developing new interests and changing old habits. It is for these groups that the day care centers, such as the center sponsored by the New York City Welfare Department, fill an urgent need. Most of the clients of these centers are public welfare recipients, many of whom live alone or are left to themselves while other members of the families with whom they reside are at work. The department reports a notable reduction in the medical care needs of their participating clients, and not one case of hospitalized mental illness among the participants (7).

Three-Generation Family

During the depression, responsible citizens first realized that changes in the social structure of family and community life and in public opinion had been so great as to render the older conceptions of family care inadequate and difficult, if not impossible, to enforce legally. For in the traditional three-generation family the rights of the elders within the family circle stemmed less from the legal obligation of their offspring than from the force of custom and strong feelings of filial obligation. These feelings survive in European culture somewhat more strongly than in our own and are still recognized in the peasant concept of *Ausgedinge* or *Altenteil* (6b). As Mumford has said, "probably at no period and in no culture have the old ever been so completely rejected as in America during the past generation" (8).

It is this loss of role and status within the three-generation family that constitutes the sociological problem of aging. Any program for the aged that does not provide a community substitute for the range of vital interests and socially valuable functions provided by the traditional three-generation family is sociologically unsound. Many current developments in community planning for older people merely aggravate this problem. They provide a segregated community of beauty, order, and convenience, with excellent housing and recreational facilities and physical and medical services. But by congregating their clients (or should I say, their victims) in segregated communities, they further isolate them from normal interests and responsibilities.

No amount of amusements and hobbies, invaluable as they are in individual cases, can provide the savor of reality and the zest for life of normal participation in the activities of a mixed community, and restore to the aged the role and status, the social acceptance and self-respect they formerly enjoyed in the three-generation family at its best. Without these, the finest provisions for housing and physical care can furnish nothing more than a first-class ghetto. As the resident of one such model project complained bitterly, "All we do here is to wait for each other to die. And each time we say, 'Who will be next?' What we want is a

touch of life. I wish we were near shops and the bus station where we could see things" (8). Man is a social being with many nonphysical needs that can be satisfied only by active participation in the common life of his fellows.

We shall not have attained a healthy and socially mature society until we have developed roles for every age category in the community and a social status commensurate with the role performed. Nothing can provide the satisfactions of gainful employment for those able and willing to continue it.

In the increased leisure of those who have successfully adjusted to retirement or semi-retirement there exists a vast potential for public and social service which we have hardly begun to tap. But such voluntary services are little more than busy work unless they are integrated as essential parts of community life. They can provide their participants with a realistic sense of doing something that is important and valuable only if they are regarded by the community as having importance and value. For this group, it is especially important to lift the barriers to employment based on chronological age and to substitute capacity to function.

Prevailing Values as Barriers

An adequate and comprehensive program of social action on behalf of the aging must await the development of a new social philosophy and its incorporation into a new set of folkways and mores with regard to their capacities and needs. Even the limited research now available in these fields is not generally known. Consequently, public opinion and policy lag considerably behind even what we know. This lag is primarily due to the resistance of the prevailing value system with its emphasis on youth, speed, initiative, and inventiveness at the expense of such qualities associated with age as maturity of experience, judgment, skill, and reliability.

Unfortunately, this lag has been in part institutionalized in plans which implement the conviction that it is desirable to retire the older to make room for the younger workers with new ideas and eager for advancement. The accent on youth has found reenforcement in such sentimental slogans as Ellen Key's, "The twentieth century as the century of the child," and more

recently by such sociological fallacies as the famous definition of the family as a group of interacting personalities built up about the child, or the emphasis of child guidance workers upon the parent-child relationship as the most fundamental of human relationships, rather than the husband-wife relationship. For not only is the husband-wife relationship prior in time to the parent-child relationship, and more enduring, but it is a major factor in determining what quality of the parent-child relationship can exist.

Perhaps we are in danger of a corresponding distortion in our philosophy of aging by such verbal legerdemain as "the golden years," and "the best is yet to be." But to those who are experiencing the realities of the departure of children, loss of spouse and friends, impairment of health and vigor, reduction of income, and loss of role and status, there is nothing either golden or good. As one resourceful lady of 72 put it, "When one has given her life to serve others, first children and later other members of the family, and when they are gone and one is all alone—there is no longer any use to live, life has lost its meaning, there is no substitute" (9).

Indeed, such expressions may become occasions of further frustration. For as Cottrell has shown, the degree of adjustment to social roles which society assigns to its categories, including age, varies directly with the clarity with which such roles are defined. Lack of clarity and consequent maladjustment result from any "discrepancies between what is given verbally and what is demonstrated in practice" (10).

A fundamental reorientation in the prevailing value system is required, since the degree of adjustment to any role varies with the consistency with which others respond to one in that role (10).

Fundamental Philosophy

It is entirely proper to take a more optimistic attitude toward old age in general than is now current, but a realistic philosophy will pander to no hopes or sentiments that are incapable of practical realization. It will recognize four basic facts:

First, that there is an irreducible number of

the aged incapacitated for participation in any active program.

Second, that there are large numbers who are capable of sufficient rehabilitation to resume activities outside their homes.

Third, that some of these lack abilities or motivation for participation in activities beyond recreation and entertainment.

Fourth, that for many others there exists an urgent need for discovering and developing economically and socially productive roles offering opportunity for continuing, even if decreasing, individual satisfaction and status in the later years. One of the most distressing aspects of aging is maladjustment from frustration due to a culture that denies roles and status to which the aged are still entitled as a matter of right by their potential contributions to the common life. But the physiological changes of advancing years make changes in social roles ultimately inescapable.

Actions designed to facilitate shifts in roles will require much more extensive and detailed sociological research than is now extant. These must include:

1. The determination of roles appropriate to the disabilities involved.

2. Technical case and group procedures to assist the aging in the process of transition. A realistic understanding of the social worth of the new role must be developed, and the aging must have opportunities to identify themselves with these roles through intimate individual contacts, imaginative practice or dramatization, or actual participation.

3. And most difficult of all, a transvaluation of the prevailing system of values in our culture so that the new roles assumed by the aging may be appreciated. This is an essential basis for any program which the aged themselves can accept as realistic and satisfying.

PHS Staff Appointments

Dr. James V. Lowry is the new chief of the Bureau of Medical Services, Public Health Service, with the rank of Assistant Surgeon General. Deputy chief of the Bureau since 1957, he succeeds Dr. John W. Cronin, who died in March 1958.

On June 1, 1958, Dr. Arnold B. Kurlander was appointed deputy chief of the Bureau; and on July 1, Dr. John C. Cutler became Assistant Surgeon General (Program Operations) in the Office of the Surgeon General, the post previously held by Dr. Kurlander. Dr. Cutler has been assistant director of the National Institute of Allergy and Infectious Diseases, Public Health Service, since the beginning of 1958.

Dr. Lowry's assignments in the Public Health Service, which he entered in 1937, have covered clinical medicine, research, and medical administration. After serving with the National Institute of Mental Health from 1947 to 1954 with the responsibility for the development of community mental health services, he spent 3 years as medical officer in charge of the Public Health Service Hospital in Lexington, Ky.

Dr. Kurlander, a member of the commissioned corps since 1940, served as tuberculosis control officer in the Arizona and Ohio State Health Departments and was assistant professor of preventive medicine at Ohio State University. He came to Washington, D. C., in 1950 as chief of the State Aid Branch, Division of Tuberculosis, Public Health Service, later becoming assistant chief of the Divi-

sion of Chronic Disease and Tuberculosis, and then chief of the Chronic Disease Program.

Dr. John C. Cutler entered the commissioned corps in 1942. Two early assignments were with the Public Health Service Venereal Disease Research Laboratory at Staten Island, N. Y., and the Pan American Sanitary Bureau for venereal disease research studies in Guatemala.

Subsequently, Dr. Cutler was detailed to the World Health Organization to direct a venereal disease control demonstration team in India.

In 1951 Dr. Cutler became chief of the Technical Aids and Services Branch of the Public Health Service Venereal Disease Division, and in 1954, program officer working in planning and evaluation of specific disease control programs in the Office of the Chief, Bureau of State Services. Three years later he was named chief program officer for the Bureau.

M. Allen Pond, who has been on detail from the Public Health Service to the Office of the Secretary of Health, Education, and Welfare since 1953, was given the rank of Assistant Surgeon General on June 15, 1958. Mr. Pond is staff assistant to the special assistant for health and medical affairs in the Office of the Secretary.

Harry G. Hanson, director of the Robert A. Taft Sanitary Engineering Center, Public Health Service, Cincinnati, Ohio, was promoted to the rank of Assistant Surgeon General on June 1, 1958.

Priorities

in

Public Health Nursing

MARGARET G. ARNSTEIN, R.N., M.P.H.

THE PROGRAM of the health department seems more complex today than ever before, though a study of history might reveal that this is not a phenomenon of our age alone but a normal attribute of a changing, growing service, a situation to be welcomed rather than deplored. Indeed we would welcome new demands for services, new heights to conquer, if we only had enough staff to send up to each new mountain top. Shortage of people in the "service" occupations exists, however, and there is every prospect that it will continue to exist in the foreseeable future. We must therefore plan to use the available staffs wisely, wisely both in terms of the community's needs and

the staff's ability to meet those needs. Health workers, like all other people, need a feeling of satisfaction in a job well done; they should not perpetually feel frustrated by their inability to do all that they see needs to be done. This requires building priorities into our program plans.

The whole subject of deciding on priorities and acting on our decision has wide ramifications into all aspects of our lives. The differences in certain philosophies and religions is primarily a difference in what has priority. Psychiatry regards a person's inability to make a decision as a definite sign of mental illness. This indecisiveness is, in other words, the inability to give priority to one activity over another at any given instant. The person who suffers from this extreme of indecision often has to be hospitalized. But I wonder whether there are many of us at large who do not suffer from some degree of the same complaint. Be-

The paper is based on a talk given by Miss Arnstein at the June 1957 meeting of the New York State Public Health Conference, while she was chief of the Division of Nursing Resources, Public Health Service. Miss Arnstein is now the Service's chief of Public Health Nursing Services.

cause of it we say we are run ragged or exhausted by all the things we have been doing. How many of us have said at one time or another, "My workload is impossible!" "I can't do everything."

If I were a cartoonist I think I might draw the public health nurse as a beast of burden surrounded by people loading packages on her back, and more people in the distance coming with more packages. The labels on the packages are so familiar that I am not going to list all of them. We would see maternal and child health, tuberculosis, and school programs already securely tied in place, and heart, diabetes, and many others being added to the load. The caption on the cartoon would be "The public health nurse as she sees herself." In order to rescue this burdened, willing worker, we must decide what size load she can carry and then choose which bundles should go on her back on the first trip, and which on subsequent ones.

In this article, I would like to discuss the process of choosing which activities should have priority rather than discussing the activities themselves and trying to put them in rank order. Putting activities in order of rank carries the implication for me that there are times when some at the bottom of the list may not be reached.

The Selection Process

First we must consider what is involved in deciding which activity should have priority; then we must act on our decisions; and finally, we must feel satisfied with our actions—that is, we must not have guilty feelings that we have neglected something we should have done. Because each of these steps is progressively more difficult, most of us use escape hatches to save ourselves in the hope that somebody else will take the helm and spare us the trouble of plotting a course through the channel. One escape hatch is blaming someone else—the health officer, for instance, or the specialized consultant; in private life, our families or even our friends. Another is unwillingness to admit that there can be any priority: everything is of equal importance and must be done. The last method of dodging the priorities issue

often comes to the fore if one tries to help a friend or co-worker cut down on his workload.

Let us review the steps we go through sometimes unconsciously when we decide on priorities.

First, we must have knowledge: knowledge of the need for the activity; knowledge of what each action entails, why it is done, what the probable results will be if it is carried out, and what will happen if it is not; knowledge as to whether we are the only ones, or the proper ones to do it.

Second, we must have analysis: that is, seeing the separate facts we have gathered as a whole and in relationship to each other.

Third, we must have acceptance of the conclusions reached in the analysis. We have to believe emotionally as well as intellectually that the decisions are right. This is particularly difficult if someone else did the analysis, for example, if the health officer, or someone in the State health department passes on the results of his analyses to the local nurse who has to carry them out.

Fourth, we must feel as competent to carry out the programs given top priority as those given low priority. This is a crucial requirement when a major change in priorities occurs. If we don't feel equally competent in both areas we have to take steps to become so. If all these steps have been taken then the ultimate goal—action—will result.

Finally, we have to feel satisfied with the activities performed according to the priorities decided upon, and satisfied with those not performed because time did not allow us to get that far down the list. This feeling of satisfaction depends not only on our acceptance of the decisions we have made, but also on our own personalities.

Everyone has a need to be loved and some people need constant reaffirmation that they are loved. For many, this means that they are approved, that all their actions are approved by everyone, that they live up to the ideal they have set for themselves, and that they think others have set for them. We call these people perfectionists. Obviously when we use these terms to describe a perfectionist his goals become ridiculous. No one can please everyone all the time. In terms of the subject of this

article, no matter which actions we give priority to there will be some who think our analysis was wrong, or our judgment was poor, or if we had just applied ourselves more diligently we could have completed the whole list. As nurses we are particularly sensitive to this type of criticism. We—the majority of us—entered nursing to help people. All the studies to date have shown this to be the outstanding motivation. Society thinks of us as helping people and a helping person should help. She should not say “no” or suggest that someone else can do the service needed.

An example from our out-of-office lives illustrates these steps though we are not, as I said, usually conscious of going through them. The following activities have been proposed for a Saturday by someone, ourselves or others: (a) pay bills; (b) clean the house; (c) go swimming; (d) write a paper for *Nursing Outlook*. (There would be other activities on the normal Saturday list but this will do for purpose of illustration.)

What are the facts? That is, what is the need for the action, and what are the results if the activities are done or left undone?

pay bills?

Facts: There are 8 bills to be paid, received almost 1 month ago. Our credit rating is now A.

Results: If the bills are paid, credit rating stays high; if not paid, credit rating might drop but this is unlikely on the basis of 1 month's lapse.

clean the house?

Facts: It is dusty, the wastepaper baskets are half-full, it is in disorder. We have a rule that the house should be cleaned at least once a week.

Results: If the house is cleaned, dust and dirt will not be ground into fabrics and they will last longer; our aesthetic senses will be gratified. If the house is not cleaned, some day in the future we will have to replace the fabrics X number of years sooner; we will have less pleasure in looking at the house; the wastepaper may overflow, which is a nuisance.

go swimming?

Facts: This is a healthful exercise. The weather is hot. We have just read an article by Dr. Paul Dudley White—who is an authority—that exercise is important in maintaining health.

Results: If we swim we will feel fine, refreshed, and enjoy ourselves, but we may feel guilty or stay up half the night doing the other things on the list. If we don't swim, we will not get refreshed, may not do other things well, will resent our decision (or when younger, our mother's decision).

write the paper?

Facts: We promised the paper by July 1. Only 1 week is left; we have 1 free half day in the office next week.

Results: If the paper is completed, we will have great sense of accomplishment, appreciation from editors for promptness; when the paper is printed, our ideas will have an influence on others and also get recognition from co-workers. If we don't write the paper, we can do some of it in the office, can get it in late and be criticized by the editors, or can risk later publication.

Then comes the complicated analysis of the relationships of all of these facts to each other, and judgment enters in because there are no statistical measures. There is no one index marked “Satisfactory Saturday.”

This is the action which might be taken on the basis of the analysis of the facts. We decide to empty the wastepaper baskets but let the rest of the house cleaning go. The facts about the relationship of dirt to length of life of the material are not clearly proved; many other factors enter in. Aesthetics are not so important as we will either be swimming or writing the paper or paying bills. We decide we can pay some bills, then we will have time to pay the rest next week. We will swim, and start the paper in the office and finish it next weekend if necessary.

We can follow this same process in making a home visit. We are all familiar with the admonition to start our health supervision visits with the family's interest, meet their needs first. We have a harder time when it comes to teaching them the procedures we learned in our

schools of nursing. There are no priorities here; every step is equally important, or at least that is the way we often were taught.

It is not easy to decide which single thing one would teach a family if only one thing could be absorbed by them. It is a very good exercise to think about priorities in this way. After deciding what should come first, think what should be taught second if only two things can be taught, and so on.

For example, the public health nurse visits a household where she finds this situation: Mike, age 12, has a streptococcal sore throat. John, age 10, has previously had rheumatic fever. The boys sleep in the same room. In her background of knowledge, the nurse has specific facts about rheumatic fever and streptococcal infections. She analyzes these and forms a judgment. Priority 1 is to keep the boys apart. Priority 2 is to keep John taking prophylactic penicillin. By the time she has helped the family work out alternate sleeping arrangements for John, various ways of making sure he doesn't go into the room to play or to get something, the family's time and concentration powers have run out. So she does not teach anything further in this visit about the isolation technique, she says nothing about boiling dishes and burning paper handkerchiefs, for she has decided these have lower priority at this time. Nor does she mention anything regarding diet and care for Mike. Obviously we could go into much greater detail and discuss why she chose these priorities and whether or not we can agree with her. But stated in brief, this case is just one illustration of the omissions which must occur at times when one plays the priority game seriously.

This analysis of what is most essential in any given situation or procedure and why it is priority 1, 2, or 10 could be an important part of our teaching in the basic professional schools of nursing. It would help sharpen our thinking to consider why we do the things we do and their relative importance under varying conditions.

The Community Program

When we apply these steps in planning a public health program for the community, we

again get the facts first. We are on familiar ground in this first step. We know we must find out what the most important health problems of a community are before we develop a specific plan of action. We are accustomed to looking at mortality data and morbidity data when the latter is available. Today in most communities in this country we would find diseases of the cardiovascular system at the top of the list, with cancer and accidental deaths among the top five. Maternal and infant mortality would be at the bottom along with deaths from the acute communicable diseases. This is one set of facts about needs of the community, but there are others which may be in conflict just as there were in the activities for a Saturday in summer which I mentioned earlier.

There are facts about the interests and demands of various groups in the community. The school principals want a health program for the school children. The physicians want nurses to give injections in the homes—to their patients with anemia, allergies, or infections. The parents want poliomyelitis "shots" for their children and perhaps themselves.

The special consultants from the State health department are each pressing us to put our efforts into such different programs as positive health guidance for mothers and children, care of the posthospitalized tuberculosis patient, care of the posthospitalized mental patient, heart disease and cancer control programs, supervision of the health of the aged, especially in nursing homes, reemphasis on immunization against diphtheria and smallpox.

There is another set of facts we gather, and that is information about the community resources available to meet some of the needs revealed by the facts already listed. We are not alone; we need not try to do the whole job ourselves.

We find the Junior Chamber of Commerce has started a hospital program of recreation for older citizens; the tuberculosis and public health association used to be very active but has not done much recently; the local heart association has just been organized; the Junior League is working in the hospital outpatient department; there are a number of inactive nurses living in the community.

Although the above listing presents a com-

plicated picture, it is not nearly as complex as a real community would be. Obviously the analysis of these facts and their relationship to each other in order to arrive at priorities in our program will require time, thought, and judgment. When all factors had been taken into consideration we would probably find that no program activity would be completely ruled out. We would do part of each, giving more time—more priority—to some than to others just as we did when planning our Saturday's activities.

Our priority plan would help us in meeting pressures for more of any given service. If it had a low priority, the group exerting the pressure would have to show why this service should be moved higher in the list, thus automatically depressing other services.

This does not mean that the plan made at the beginning of the year, the beginning of the week, or even the day's plans can always be followed. In health work there are always emergencies; there are always unexpected demands. It may be poliomyelitis vaccination

clinics, or an influenza epidemic, or a special study of new drugs for home treatment of some disease which claims our attention. These may have to take priority for short periods over all other activities in our program plan. When this happens the decision has often been made by someone else, but if we understand the reason for the decision we can accept it and give it first consideration in our own minds.

In summary, in order to establish priorities we first must have knowledge based on facts and experience; we must make an analysis of the relationships of the various facts; then, because there are no mathematical formulas to show us which activity should have priority, we must use judgment in the interpretation of our analysis. The action we take, the program we carry out, is the result of the above procedures. We can then go home—if we have dealt with our personal need to please everyone—at the end of each day, at the end of each year, satisfied that, according to our best knowledge and judgment, what has been left undone was less important than what has been done.

U. S. Injury Estimates, July–December 1957

During the last half of 1957 about 25 million Americans were injured seriously enough to require medical attention or to limit their activities for at least a day, according to a preliminary report by the Public Health Service's U. S. National Health Survey.

Injuries during this period resulted in almost 214 million days of restricted activity, including 55.5 million days spent in bed at home or in a hospital. The report also shows:

- Home accidents injured 10,065,000 people, or 40.3 percent of all injured.
- Work accidents injured 4,173,000, or 16.7 percent.
- Motor vehicle accidents injured 2,444,000, or 9.8 percent.
- Other kinds of accidents and injuries resulting from violence involved 8,267,000, or 33.1 percent.
- Of the total injured, 14.1 million were males and 10.8 million, females; 14.9 million were urban residents; 7.1 million lived in rural nonfarm areas; and 3 million lived on farms.

The Preliminary Report on Number of Persons Injured, United States, July–December 1957 is the third in a series based on continuing nationwide household interviews, conducted for the Public Health Service by the U. S. Bureau of the Census.

Budgeting a Combined Health Department

A. D. SIDIO, M.S., and JOHN S. ANDERSON, M.D.

MERGING separate city and county health departments into one organization results in certain advantages, but specific obstacles must be overcome before the combined unit can be considered successful.

The foremost problem confronting any such combined department is that of obtaining an adequate budget. This is sometimes complicated by the city and county governments' differing on the amount each should contribute to the health department budget. Theoretically, the amount should be worked out between the two governments without any help or hindrance from the health department. When agreement is lacking, however, the department may find itself in the unwanted but necessary position of arbitrator, especially if lack of agreement threatens dissolution of a combined unit before there has been sufficient opportunity to demonstrate the advantages of combination.

The Pueblo City-County Health Department in Colorado was organized in July 1952. By written agreement, the city and county of Pueblo gave the new department the balance of the funds unexpended from the budgets of the former health departments, with which the new department was to operate until January 1953. Unfortunately, the written agreement between the city and county of Pueblo, permitting the formation of the department, contained nothing concerning the future financing of the de-

partment. This was a serious oversight, for the city and county governments had diametrically opposite viewpoints on the matter.

Pueblo County has a population of about 120,000. Approximately 80 percent of the population is in the city of Pueblo. There are only two, very small, incorporated communities in the county besides Pueblo. Most of the remaining population is in the fringe around the city of Pueblo.

City and County Debates

Before 1952, the county health department consisted of two nurses, a sanitarian, and a part-time health officer. Compared with the city health department, the operation was small. After the merger, the county government reasoned that its share would be proportionate to the population of the county excluding the city of Pueblo.

The city government postulated that since the residents of the city paid county taxes, they should expect to get health services from the county. In the city's opinion, it would be logical for the city to withdraw all its contributions and let the county assume the entire operation of the health department. The county countered by explaining that since the people of the city lived in a congested area, they had more public health problems, would need more health department services, and should expect to contribute more to the budget.

This debate continued each time the health department budget was presented from 1952 to 1956. Much time was wasted by all concerned. In 1955, the health officer went to 10 meetings in which the proportionate share of the budget was the only item discussed. Each year, some

Mr. Sidio is sanitation chief for two districts in the Allegheny County Health Department, Pittsburgh, Pa. He was formerly director of environmental sanitation for the Pueblo City-County Health Department, Colo. Dr. Anderson is director, Pueblo City-County Health Department.

Public Health Reports

kind of compromise was reached; yet neither government felt that the arrangement was equitable.

In 1956, a complete impasse was reached in what had now become the routine annual health department budget conferences. Everyone had grown weary of hearing the same arguments over and over again without resolution. The inability of the two governments to reach agreement had nullified the otherwise increased efficiency of the health department. The dissolution of the combined department was imminent.

Devising a Formula

At this crucial moment, the department found it necessary either to assume the undesirable position of arbitrator or to see several years of hard work and progress go for naught. An attempt was made to express in mathematical terms population, taxes, and services within the city and county area outside the city. Population was eliminated as a necessary ingredient in the formula since for several reasons the services were not given on a proportionate basis. For example, the department provided the school nursing program in the county area, while the city schools had continued their own nursing program at the time. The idea was that, if the formula could correlate the extent that the city population was taxed with the amount of health services they received, the city's share of the budget could be determined equitably.

The formula, as originally presented to simplify explanations, was as follows:

$$C + E_c (B - C) = S_c B$$

where

C = The city's share of the health department's budget.

E_c = The assessed valuation of the city, expressed as a percentage of the total county valuation.

B = The net budget to be divided between the city and the county. (State contributions, income on vital statistics, and other funds would be subtracted from the gross budget to obtain the net budget.)

$(B - C)$ = That part of the budget paid by the county.

S_c = The percentage of the health department services provided inside the city.

The left side of the formula is the entire amount paid by the city, the funds coming

from the city's separate contribution and from the county for the county taxpayers living in the city. The contribution by the city subtracted from the total net budget represents the amount paid by the county. When the amount paid by the county is multiplied by the percentage of the county valuation inside the city, the portion of county taxes collected from the city residents is accounted for.

The right side of the formula represents what the city receives for the moneys paid. If the city receives a certain percentage of the services of the health department, then it is obligated to pay that percentage of the budget. This also holds true for the county. The formula is based upon each paying for the services received.

A similar formula could be worked out to determine the county's share, but this would be unnecessary. The formula is set up to determine the city's share of the budget, and the county's share can be determined by computing $(B - C)$.

Calculating the City's Share

Except for S_c , all factors in the formula were known. The percentages of services provided in the city (S_c) could be determined from the daily activity reports in the Pueblo City-County Health Department. Statistically, this figure can be determined within reasonable accuracy without adding appreciably to the time required to prepare daily activity reports. The department personnel had been preparing activity reports for several years, although no differentiation between city and county work was made prior to January 1, 1956.

The manner in which the services given to the city is calculated seems complicated, but actually it is very simple administratively. Each person in the field codes the number of hours spent for the city and county. Office time and time spent on activities that cannot be conveniently broken down into city and county components are ignored, since they should be proportionate to the time spent on the various activities in the field.

General expenses, such as the health officer's salary and commodities used by the entire department are assumed to be proportionate to the division of the field services. Since field services were coded in the past, it did not add to the

department's administrative effort to code for the city and county breakdown.

For example, during the month of June, sanitarian "A" spent 87 hours for the city and 30 hours for the county in the field, thus 74 percent of his services were allotted to the city and 26 percent to the county. The entire division of sanitation field services were coded and tabulated in a similar manner. For the month of June, the department spent \$1,599.81 for salaries and retirement for the sanitarians doing work in the city. This was 69 percent of the total. In addition to the sanitarians, the sanitation section has other expenses such as the supervisor's salary, the secretary's salary, automobile expenses, vacation and sick leave, and laboratory expenses. All the above expenses are prorated by 69 percent and charged to the city. The sanitation section expended \$2,402.26 (69 percent) for the city and \$1,079.28 (31 percent) for the county during the month of June 1956.

The same procedure is used for the nursing, meat inspection, and vital statistics sections. These are the services that can be accurately divided into city and county components. The expenditures of each of these sections, according to the city and county divisions, are then totaled. In June, this amounted to \$6,505.11 (66 percent) for the city and \$3,327.20 (34 percent) for the county.

With the calculations for S_c completed, all factors in the formula were known.

Explaining the Formula

Our first problem, after we had established the validity of the formula through several critical reviews, including a legal review, was to explain the formula to officials unaccustomed to thinking in algebraic terms. The first step was to transpose the formula in order to show the city's share of the health department's budget. Thus:

$$C = \frac{B(S_c - E_c)}{1 - E_c}$$

Hypothetical values were then substituted for

the symbols in our explanation. For if the city had 50 percent of the assessment and the health department was given city 50 percent of its services, then the government should not be required to supply additional money to the department. As that the budget is \$100,000, then

$$C = \frac{\$100,000 (0.5 - 0.5)}{1 - 0.5} = \frac{\$100,000 \times (0)}{0.5} =$$

If, however, the assessed valuation remained at 50 percent, but the city receives more services, then the city would be required to provide additional funds. Assuming that the net budget remained at \$100,000 and the city received 75 percent of the health department's services, the city's additional obligation can be determined:

$$C = \frac{\$100,000 (0.75 - 0.5)}{1 - 0.5} = \frac{\$100,000 (0.25)}{0.5} = \$50,000$$

As the result of our efforts to devise a formula and our success in explaining it, both city and county governments agreed that the formula provided a fair and equitable means of determining their share of the budget. A contract incorporating the formula was prepared and signed by both parties.

Conclusion

It is felt that this formula can be used successfully by other departments. The type of service will vary with each department, but the coding procedure can be adapted to meet the individual situations with ease.

The formula would be particularly applicable to combined departments where more than one governmental unit contributes to the budget. This would be true where several counties were combined into a district health department or where several cities within the jurisdiction of a county health department are expected to contribute to the department budget. The use of the formula should tend to eliminate much unnecessary work for those seeking approval for combined health department budgets.

Hospital records show that accidental injury is the chief cause of hospitalization, followed by hernia, heart disease, and tuberculosis. Leading causes of deaths are malignant neoplasms and heart disease.

Health Problems of American Seamen as Measured by Hospital Statistics

ROBERT W. BARCLAY, A.B., and EDYTHE A. GRAY, A.B.

THE HEALTH of seamen has long been a matter of concern to major maritime powers. In the United States, Congress authorized the President "to provide for the temporary relief and maintenance of sick or disabled seamen" in 1798, making merchant seamen the first group in this country eligible for medical care through Federal legislation. This action by Congress gave support to an industry that was an integral part of our national defense forces and vital to our foreign trade. At the same time, it provided the means for coping with a public health problem.

To a considerable degree, the public health problem of itinerant seamen without community ties has diminished. Living conditions on ships at sea and in boarding houses ashore have improved dramatically over those chronicled at the turn of the century. But seamen today continue to constitute a unique group whose occupation warrants special consideration of their health problems.

The merchant marine, long recognized as the "fourth arm of defense" and essential to foreign trade, is also an industry that requires a

high degree of risk to the health and physical well-being of its labor force. Seamen must undergo exposure to diseases through foreign travel as well as the health hazards of shipboard life. Close confinement and lack of professional medical attention for long periods when vessels are at sea are factors which can have far-reaching influence on health. In port, the seaman is frequently in need of medical care in a location many hundreds of miles from his home. For these reasons the United States and other maritime nations have seen fit to make special provision for the health needs of seamen.

Since seamen crews of merchant vessels are world travelers, national interest in the health of seamen has led to international recognition of the problem. In the early 1800's the United States Congress authorized the care of seamen from foreign-flag vessels in our marine hospitals, as they were then known, at the expense of the shipping operator. With the development of wireless communication, a program of medical advice to ships at sea was adopted that is today virtually worldwide. Lists of international venereal disease treatment facilities have been published for many years. More recently, a Joint International Labor Organization-World Health Organization Committee on the Hygiene of Seafarers has been formed.

In the United States, medical care is pro-

Mr. Barclay is program analysis and reports officer of the Bureau of Medical Services, and Mrs. Gray is chief of the Biometrics Section, Statistics and Reports Branch of the Bureau's Division of Hospitals, Public Health Service.

vided for all seamen actively engaged in their occupation on American-flag vessels. Seamen with 60 days of continuous sea service are eligible for medical care while actively engaged in this work and for a 90-day period following their last sea service. We estimate that the number eligible for health services who were employed on vessels navigating the deep seas, the Great Lakes, and coastal and inland waterways averaged 162,500 in 1956 and 166,000 in 1957. (The year here and elsewhere in this paper refers to the Federal fiscal year, July 1-June 30. The estimate of employees is based on data in the Maritime Manpower Report and other information from the Maritime Administration in the Department of Commerce, the Fish and Wildlife Service in the Department of the Interior, and the American Waterways Operators, Inc.)

Seamen on American-flag vessels receive inpatient and outpatient medical and dental care through a network of Public Health Service facilities that also minister to the health needs of Coast Guard personnel, Federal employees with a job-related, compensable injury or illness, and several other categories of beneficiaries. The facilities used by seamen include 12 general medical and surgical hospitals, a tuberculosis hospital, and 2 neuropsychiatric hospitals. In addition, 26 outpatient clinics staffed with full-time personnel are operated in ports along the seacoasts and waterways in this country and its possessions. In another 98 locations, where the caseload does not warrant a full-time activity, care is supplied through contracts with private physicians for part-time service. Outpatient facilities are authorized to use local hospitals in emergency situations until patients can be transferred to the nearest Public Health Service hospital. Seamen receive about 40 percent of the total volume of care provided by these facilities. The following data indicate the level of utilization for seamen:

	1956	1957
Inpatient admissions.....	24, 184	25, 104
Average daily census.....	2, 359	2, 360
Inpatient discharges.....	23, 967	24, 658
Outpatient visits.....	438, 000	454, 973

It would be difficult to compare these gross measures of health services with standard or

average hospital utilization rates for the general population. The precise age-sex composition of the seaman labor force cannot be ascertained, and little is known about the extent to which seamen use health services outside Public Health Service auspices. These factors, however, do not preclude the development of a considerable quantity of informative material through analysis of hospital morbidity and mortality statistics. The causes of hospital admission and of hospital deaths are valid indicators of the major health problems of seamen. These data are reported to Washington for each patient discharged by Public Health Service hospitals and contract facilities. Information for seamen discharged in 1956 and 1957 forms the primary source of the data which follow. Ninety-nine percent of the patients were men. More than four-fifths were white; Negroes accounted for 10 percent, and another 3 percent were of other ethnic groups.

Causes of Hospitalization

Injuries due to accidents head the list of causes for admission of seamen to hospitals. Other most frequently named causes are hernia, heart disease, tuberculosis, ulcers, and malignant neoplasms (table 1). These conditions

Table 1. Leading causes for hospital admission among seamen discharged from Public Health Service and contract hospitals, 1956 and 1957

Cause for hospitalization	1956		1957	
	Number	Rate per 100 discharges	Number	Rate per 100 discharges
All causes.....	23, 967	100. 0	24, 658	100. 0
Accidents (800-999).....	3, 173	13. 2	3, 385	13. 7
Hernia (560-561).....	1, 465	6. 1	1, 614	6. 5
Heart disease (410-443).....	1, 424	5. 9	1, 376	5. 6
Tuberculosis (001-019).....	1, 173	4. 9	1, 204	4. 9
Ulcers of stomach (540-542).....	768	3. 2	752	3. 0
Malignant neoplasms (140-205).....	756	3. 2	739	3. 0

NOTE: Figures in parentheses are category numbers of the International Statistical Classification, 1948.

Figure 1. Hospitalization of seamen for venereal disease, Public Health Service and contract hospitals, selected years.

represent the cause for about one-third of the hospitalizations of seamen, and they account for slightly less than one-half of their total days of hospitalization each year.

Injuries due to accidents were the cause of hospitalization for more than 13 percent of the discharged patients in 1956 and 1957. The high standing of this category among the conditions leading to hospital admission is a reflection of the hazardous nature of the seaman occupation. In its Accident Facts for 1957 the National Safety Council reports that the marine transportation industry had the highest rate of disabling injuries (number of injuries per million man-hours) among 40 major industry groups. The 3,173 seamen discharged in 1956 following hospitalization for treatment of injuries included 989 patients with fractures (excluding those of skull and face bones and fracture residuals); 812 with open wounds, contusions, and the like; 614 with dislocations, sprains, and strains; 371 with intracranial injuries; and 387 with other injuries.

There has been little change in the relative frequency of injuries due to accidents as a cause of hospital admission among seamen during the past 10 years. This condition has ranked first since the late 1940's. Before then, however, venereal disease was the most frequently named cause of hospital admission. There were entire

wards set aside in Public Health Service hospitals for long-term treatment of syphilis. With the introduction of penicillin, hospitalization of seamen with venereal diseases was sharply curtailed. Although approximately the same number of seamen were discharged from hospitals in 1930 and in 1957, admissions for venereal disease amounted to more than 5,000 in 1930 as compared with 265 in 1957. As recently as 1948, venereal diseases have accounted for a substantial share of the hospitalizations of seamen (fig. 1).

The list of leading causes for hospitalization of seamen reflects some conditions traditionally associated with the maritime industry, such as accidents and tuberculosis. It also includes two relative newcomers, heart disease and malignant neoplasms. The number of seamen with these latter conditions indicates that the average age of the seamen labor force is increasing. This indication is borne out by analysis of the age distribution of the seaman discharged from hospitals. Between 1948 and 1957 the median age increased from 37.9 to 47.0 years; in 1957, seamen 65 years of age and older outnumbered those under 25 years of age (fig. 2).

The frequency rates for the leading causes of hospital admission vary considerably according to the age of the patients. Accidents represent a relatively small share of the conditions treated among older patients, who tend to have

Figure 2. Age at time of hospital admission of seamen discharged from Public Health Service and contract hospitals, 1957.

substantially more heart disease and malignant neoplasms (table 2).

Seamen treated only for accidental injuries during a period of hospitalization had an average length of stay of 17 days in 1956. This compares with 15 days for seamen with a diagnosis of hernia, 23 days for those with heart disease, 111 days for those with tuberculosis, 20 days for those with ulcers, and 35 days for those with malignant neoplasms. These figures are based on single-diagnosis cases not requiring further immediate hospitalization. Transfer cases are excluded.

These differences in length of stay for the leading causes of hospital admission and the variation with age in types of conditions treated help to explain why older seamen tend to be hospitalized for longer periods than younger ones. Other factors are contributory, however. Older patients tend to be treated for more conditions per hospital admission than younger seamen and to remain hospitalized longer even for the same conditions. The variation in length of stay by age group is shown below:

Age (years)	Median stay (days)
All ages.....	17
Under 25.....	10
25-34.....	13
35-44.....	15
45-54.....	18
55-64.....	22
65 and older.....	23

Causes of Hospital Deaths

A total of 518 hospital deaths were reported for seamen in 1956 by Public Health Service hospitals and contract facilities. Of this number, 208, or 40 percent, were attributed to malignant neoplasms. The next most frequently named cause was heart disease, which accounted for 109, or 21 percent, of the hospital deaths (table 3).

For all males in the general population, heart disease is the leading cause of death, both in and out of hospitals. Heart disease deaths far outnumber the deaths attributed to malignant neoplasms. This same relationship is observed among male patients dying while hospitalized under the Saskatchewan Hospital Service Plan.

Table 2. Leading causes of hospitalization for seamen, by age: rate per 100 discharged patients, Public Health Service and contract hospitals, 1956

Cause for hospitalization	Age at time of admission (years)		
	Under 45	45-64	65 and older
Accidents.....	17.6	10.1	5.8
Hernia.....	4.6	7.7	5.2
Heart disease.....	1.6	8.5	17.6
Tuberculosis.....	4.2	5.5	4.0
Ulcers of stomach.....	3.2	3.5	1.3
Malignant neoplasms.....	1.0	4.3	10.0

NOTE: For International Statistical Classification numbers for cause categories, see table 1.

Of 1,853 male deaths reported by general hospitals of Saskatchewan in 1951, 447 were the result of malignant neoplasms as compared with 532 caused by heart disease. Among the seamen included in our study, however, the number of deaths from malignant neoplasms is almost twice the number of deaths attributed to heart disease. (The Saskatchewan data were supplied by the Division of Public Health Methods, Public Health Service, which obtained them from the Saskatchewan Hospital Service Plan.)

This difference is probably explained by the effects these diseases have on the employment pattern of seamen. Seamen with heart disease

Table 3. Hospital deaths among seamen, by age, Public Health Service and contract hospitals, 1956

Cause of death	Age at time of admission			
	All ages	Under 45	45-64	65 and older
All causes.....	518	73	332	113
Malignant neoplasms (140-205).....	208	23	139	46
Heart disease (410-443).....	109	7	72	30
General arteriosclerosis (450).....	27	0	15	12
Cirrhosis of liver (581).....	26	2	19	5
Tuberculosis (001-019).....	18	3	11	4
All other.....	130	38	76	16

NOTE: Figures in parentheses are category numbers of the International Statistical Classification, 1948.

which is not rapidly progressive to death become unfit for duty at sea and consequently lose their eligibility for medical care. The end result of the disease in these patients is not reflected in these figures. Malignant neoplasms, however, frequently cause relatively quick death. Hence, many more seamen with malignant neoplasms than with heart disease are likely to be eligible for care throughout the course of their disease.

That the older seamen tend to leave the labor force is indicated by a comparison of the ages of hospitalized seamen and of Saskatchewan males. In Saskatchewan in 1951, the proportion of discharged patients 65 years of age and older was 20 percent. The corresponding figure for the seamen in our study was less than 7 percent.

Adjusting for the difference in ages between the seamen and the Saskatchewan males would not change the picture substantially. Of the deaths of seamen aged 45-64 years, 139 were attributed to malignant neoplasms and 72 to heart disease, still a ratio of 2 to 1. The number of deaths due to malignant neoplasms among Saskatchewan males in this age group was 130 as compared with 139 for heart disease.

Another comparison for discharged patients aged 45-64 years, however, shows that the proportions of hospital admissions for malignant neoplasms were approximately the same among seamen and Saskatchewan males. Heart disease, on the other hand, was the cause of hospitalization for a greater proportion of the seamen (table 4).

These data support the hypothesis that seamen with heart disease leave the maritime labor force and thereby lose their eligibility for medical care. The fact that deaths due to malignant neoplasms far outnumber those caused by heart disease among seamen receiving medical care in Public Health Service and contract facilities cannot, therefore, be interpreted as evidence of an association between the seaman occupation and malignancies.

Tuberculosis, like malignant neoplasms and heart disease, ranks high as a cause of death

Table 4. Malignant neoplasms and heart disease among hospitalized seamen and Saskatchewan males aged 45-64 years

Cause for hospitalization	Seamen		Saskatchewan males	
	Number	Rate per 100 discharges ¹	Number	Rate per 100 discharges ²
Malignant neoplasms	491	4.5	561	4.4
Heart disease	973	9.0	1,029	8.1

¹ Based on total of 10,842 discharged patients, excluding tuberculosis patients.

² Based on total of 12,780 patients discharged from general hospitals.

as well as a cause of hospitalization. In 1956, 18 deaths among hospitalized seamen were attributed to tuberculosis, about 3.5 percent of the total hospital deaths. This figure is considerably smaller than the proportion in past years. Tuberculosis accounted for 15 percent of the hospital deaths among seamen in 1948 and 5 percent in 1954.

Summary

Examination of morbidity and mortality statistics from Public Health Service hospitals and contract facilities indicates that accidents, hernia, heart disease, tuberculosis, ulcers, and malignant neoplasms are today the major health problems of American seamen. These conditions represent the cause for about one-third of all hospitalizations of seamen and account for slightly less than one-half of the days of inpatient care they receive.

Venereal disease, once the leading cause of admission to hospitals among seamen, has virtually disappeared as an illness requiring inpatient care.

Malignant neoplasms and heart disease are named as the underlying cause for 60 percent of the hospital deaths. Deaths due to tuberculosis have decreased sharply from levels of a few years ago.

Association of Bats with Histoplasmosis

CHESTER W. EMMONS, Ph.D.

TWO YEARS ago, a family moved into an old frame dwelling in a rural neighborhood near Clarksburg, Md. Shortly thereafter several members of the family became ill with histoplasmosis. The number of bats living in the attic of the house, the quantity of bat guano in the attic and on the ground adjacent to the foundation walls, and the isolation of *Histoplasma* repeatedly from all four sides of the house out to a distance of 5 feet suggested the source from which one fatal and several clinical illnesses in the family were acquired. A clinical report of this outbreak will be made separately.

The environmental conditions associated with this family epidemic may be significant in explaining the epidemiology of certain cases of histoplasmosis occurring in rural families. They may be especially significant in explaining the puzzling distribution of histoplasmin sensitivity and cases of histoplasmosis in certain towns and cities where there is no known association with chickens and where saprophytic sources of *Histoplasma* have not yet been detected.

The saprophytic growth of *Histoplasma* in soil is so frequently associated with chicken excreta that it receives the immediate attention of the epidemiologist confronted by a case of histoplasmosis. The patient is questioned carefully concerning the presence of chickens in his environment and the extent of his exposure to them. Any episode involving removal of litter

and excreta from a chicken house, or its use as a fertilizer on garden or lawn, is at once assumed to have provided the effective exposure. Laboratory isolation of *Histoplasma* from the material under suspicion often strengthens this assumption. However, a preoccupation with the patient's exposure to chicken excreta may lead to oversight of other associations which can be equally important but which have not received general recognition.

Zeidberg and associates (1) first called attention to the association between chickens and the saprophytic growth of *Histoplasma* in soil fertilized by their excreta. The first isolation of *Histoplasma* from soil was from a specimen collected under a chickenhouse, although the building was not identified in the report (2). This association has been widely recognized and confirmed by many investigators. Many isolations of *Histoplasma* from sites not associated with chickens have been reported, however. These include the earthen floor of a meathouse, miscellaneous farm buildings and a dog pen (3, 4), an old unused silo (5, 6), river water (7), a storm cellar, an old water tower, an old chalk mine, soil under a residence, low moist woodland, an abandoned schoolhouse (8, 9), and a hollow tree trunk (8-10).

One recognized association has been with caves known to be sources of infection for speleologists, casual visitors, or persons working in caves in the mining of guano or collection of other materials. In 1948, Washburn, Tuohy, and Davis (11) reported pneumonitis occurring in persons entering a cave. It is not reported whether bats were present. They called this disease "cave sickness" and suggested that it was a new disease entity. The patients did not re-

Dr. Emmons is with the Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, Public Health Service. W. R. Piggott, W. Mitchell, and W. B. Hill, Jr., also with this laboratory, provided technical assistance.

act to histoplasmin or coccidioidin down to dilutions of 1:100 and 1:10, and no complement-fixing antibodies to these antigens could be shown in any of the 21 persons who became ill. On the basis of X-ray appearance, symptomatology, and one isolation of *Histoplasma* from the mouth of the cave, Grayston and Furcolow accepted this epidemic as histoplasmosis (8, 9).

An epidemic of proved histoplasmosis occurred in persons entering a cave in Venezuela (12, 13). Conversion to histoplasmin sensitivity and significant complement fixation titers were demonstrated, and *Histoplasma* was isolated from 4 of 5 soil samples taken. The cave sheltered a large colony of bats.

Cases of histoplasmosis occurred in 46 persons entering caves sheltering bats in the Transvaal in South Africa (14). Animals placed in one cave were also infected, and *Histoplasma* was isolated from the tissues of these animals. Speleologists from the Cape of Good Hope who have not entered caves in the Transvaal have remained histoplasmin-negative.

A cave in Peru has been described as the source of histoplasmosis, formerly known locally as "fiebre de Tingo Maria" (15). This cave is inhabited by a nocturnal fruit-eating bird (*Steatornis caripensis*), sometimes called the "oil bird" because of the oil obtained from its fat, which is highly prized by residents of the area. Many susceptible persons entering the cave to collect these birds have developed a pneumonitis which is now recognized as histoplasmosis. *Histoplasma* was isolated from soil in the cave, and its presence there was attributed to enrichment of the soil by droppings of *S. caripensis*. However, it is known that bats also inhabit the cave. Grayston and Furcolow, in reviewing epidemics of histoplasmosis (8), mention a personal communication from Dr. E. Englert, Jr., who observed pneumonitis in persons who scraped quantities of bat dung from the timbers of a bridge in Maryland.

Methodology

The methods used in the present study for isolating *Histoplasma* from soil were those described in 1954 (3), and were only slight modifications of the methods used in the original isolation of *Histoplasma* from soil in 1949 (2).

Soil specimens were scooped up directly into sterile 25 by 50 mm. pyrex test tubes and the cotton stoppers were replaced to permit drying of the specimens. If the specimen is sealed, as by a screwcap top, the humidity of even a moderately dry soil encourages germination of fungus spores, germination of weed seeds, and activity of microfauna with a resultant rapid change in the microflora.

Immediately upon return to the laboratory, 10 to 15 ml. of the specimen was removed to another 25 by 150 mm. tube, 0.8 percent sodium chloride solution was added nearly filling the tube, a sterile rubber stopper was inserted, and the suspension was shaken vigorously for a half minute. The suspension was allowed to sediment for 10 to 15 minutes and 5 to 10 ml. of the supernatant was removed by pipette to a conical glass or small beaker. For each ml. of the supernatant, 0.25 ml. of an antibiotic solution (2 mg. streptomycin and 5 mg. penicillin per ml. water) was added and 1 ml. of this inoculum was injected intraperitoneally into each of 5 or 10 Swiss, white, general-purpose mice. The mice were killed after 4 weeks and cultures were made from liver and spleen. In the specimens with a high fecal content, it was sometimes necessary to increase the amount of antibiotic or to treat the inoculated mouse with antibiotics the next day. The remainder of the original soil suspension was held at room temperature for reexamination if necessary.

The House and Its Environs

The repeated isolation of *Histoplasma* from soil adjacent to the foundation of a bat-infested house near Clarksburg, Md., where several cases of histoplasmosis occurred, points to a relationship between this disease and the presence of the house bat.

My attention was brought to the Clarksburg episode when Dr. Donald Pohl, of the Children's Hospital in Washington, D. C., referred an infant with severe histoplasmosis to the Clinical Center of the National Institutes of Health in Bethesda, Md. The child had acquired a fatal infection shortly after its family had moved into the old house. Several of its siblings were also ill.

I first visited the premises with Dr. Pohl on

October 10, 1956. The only large building on the premises, where presumably the children were infected, was an old, 2-story frame residence (see illustration). The only other structures were a small shed 40 feet east of the house, which had been used many years before for chickens but was now a doghouse and storage shed, and a privy 150 feet southwest of the house.

The front dooryard consisted of bare, firm, clay soil, with a patchy lawn of bluegrass and other grass beginning about 15 feet from the house. The lawn east of the house sloped to the south and consisted of grass and weeds intersected by a bare soil pathway, deepened by erosion, extending nearly parallel to the east wall and 3-15 feet distant from it. The back dooryard to the south, except for small patches of grass and weeds, was bare for several feet adjacent to the house. Beyond an apple tree, which supported a child's swing, was a scattered accumulation of refuse where trash had been burned and ashes had been dumped. West of the house was a weedy grass lawn, sloping to the south.

The house was in poor repair, with loose siding and cornices containing apertures sufficiently large for the entrance of bats. One conspicuous irregular hole in the siding halfway up the east wall of the house was approximately 4 by 10 inches in size and showed evidence of frequent use. Bat dung was apparent on the ground adjacent to the solid stone and cement plastered foundation on all four sides of the house. It was especially abundant on the west side of the house where large quantities had fallen from the roosting sites of the bats in the attic and wall, and had accumulated between the exterior siding and the inner wall of the house. From this voluminous deposit, it had sifted out between the loose siding boards to the ground.

The family was aware that the house sheltered a colony of bats, and inspection of the attic revealed a large colony of the common brown bat or house bat, *Eptesicus fuscus*, and several bushels of bat guano. Sixteen bats were captured and brought to the laboratory where they were killed, measured, identified by the writer, and spleen, liver, and lung were cultured for fungi. In order to utilize more fully the

Histoplasma was isolated from soil adjacent to the stone and cement plastered basement wall on all four sides of this house. The hole in the east wall of the house and holes in the cornices were used by bats to gain entrance to the attic.

material, the brains were removed, pooled, and injected into mice in a test for rabies. No pathogenic fungus was isolated, and no Negri bodies were found by A. C. Faber who examined the mouse brains.

Isolations From Soil

When the premises were first visited in October, 28 soil samples were collected. Ten of these were adjacent to the doghouse and 18 were taken adjacent to the foundation of the house, the outside entrance to the basement, and inside the basement. As these latter samples were collected, we observed many bat droppings which had sifted out from accumulations under the loose siding or had fallen to the ground as bats entered the attic. Three of the ten samples taken adjacent to the doghouse were positive. *Histoplasma capsulatum* was isolated from 1 of 5 samples taken inside the cellar and from 11 of 13 samples taken adjacent to the foundation. It is noteworthy that positive samples were obtained from all four sides of the house.

On a second visit to the home on March 11, 1957, two samples were collected from soil adjacent to the foundation on the north side of the house. Both were positive.

On June 26, 1957, 24 hours after a 1-inch rain, 21 collections were made. The soil was

moist but well drained. Ten specimens were taken at approximately 1-foot intervals in a northerly direction from the north side of the house, across the front dooryard which was composed largely of bare, hard-packed earth, extending to the bluegrass sod lawn beneath an oak tree 25 feet from the house. *Histoplasma* was isolated from only one specimen collected adjacent to the foundation.

Cryptococcus neoformans was isolated adjacent to the foundation and from specimens taken 3 and 5 feet from the foundation. When this series of specimens was collected, expectorated sputum was observed on the moist soil at several points. The patches of sputum were avoided in collecting soil samples, but it was assumed that many other sputums, no longer visible, had been spit upon the yard adjacent to the front porch and elsewhere on this side of the house. The time interval since recovery from histoplasmosis of all surviving members of the household would preclude relating these sputums to pulmonary histoplasmosis, but they might relate to the isolation of *Cryptococcus* from these sites, where *Histoplasma* was not found.

Three specimens were taken adjacent to the foundation and at 1-foot intervals eastward from the northeast corner of the house; all were positive for *Histoplasma*. All five specimens taken at the foundation and at 1-foot intervals eastward from the southeast corner were positive. Of the three specimens taken near the foundation on the west side of the house *Histoplasma* was isolated from two, and all mice receiving the third specimen died within 24 hours.

Collections were made again on July 11, 1957, at a time when the soil was quite dry. Specimens were taken adjacent to the foundation and at approximately 1-foot intervals along three parallel lines running eastward. Among 10 specimens collected along the first line, only one adjacent to the foundation and one 1 foot from it were positive. Of 10 specimens along the second line, 4 from the sites marked at 0, 1, 2, and 3 feet and a fifth 6 feet from the foundation, were positive. Along the third line, 5 of 6 specimens taken adjacent to the foundation and out to a distance of 5 feet were positive.

Collections were made on August 22, 1957,

when the soil was dry, and specimens were taken adjacent to the foundation and at approximately 15-inch intervals running eastward from the house foundation, most of these specimens being from underneath bluegrass sod. Of 10 specimens, only the 4 adjacent to the foundation and extending out to 3½ feet were positive.

Eighteen soil samples were collected on September 30, 1957, again adjacent to the northeast corner of the house and running eastward at intervals of 1 to 3 feet. The first 5 specimens, extending to 3 feet from the foundation, were positive for *Histoplasma*. *C. neoformans* was isolated from the sixth specimen, which was in a footpath 5 feet from the house. *Histoplasma* was isolated from one specimen 9 feet from the house.

It seems apparent from the sampling already done that *Histoplasma* can be isolated consistently from soil adjacent to the foundation of this house and that its ability to grow here is related to the presence of bat droppings. It is further remarkable that there is no apparent association with chickens or other birds. The precise interval since chickens had been kept on the premises was not known by the residents except that it had been many years before. It is further remarkable that, although most of the studies of the spatial relationship were made on the north and east sides of the house, *Histoplasma* was isolated on all four sides, including the south side which was somewhat shaded by an elevated porch and a tree and the west side which had no protection from the sun.

Since the study was begun, we have been comparing selected soil samples taken near the foundation and positive for *Histoplasma* with samples taken at a distance of several feet and from which *Histoplasma* was not isolated. The soil is acid (pH 5.3-6.7) without consistent or significant differences in pH reactions between positive and negative soils. Unweathered bat dung has a pH reaction of 6.2 to 7.1. To date, although several hundred fungi have been isolated, we have not recognized significant differences in the microflora of positive and negative specimens. Sampling will be continued throughout 1958 in an investigation of the extent to which distribution of *Histoplasma* is limited on these premises and in a further search for seasonal differences, for histoplasmosis in

bats, and especially for micro-organisms which may either stimulate or inhibit *Histoplasma* in the highly competitive environment of soil.

Conclusion

The special significance of this study relates to a possible explanation of the prevalence of histoplasmin sensitivity and the occurrence of clinical cases of histoplasmosis in certain urban areas where the sources of infection are not yet recognized. It is a well-known habit of the brown bat (*E. fuscus*), sometimes called the "house bat," to live in crevices and attics of old houses, and "it is often seen about street lights in large cities where it finds congenial habitation in dark nooks in the roofs or in accessible crannies in the buildings" (16). Solitary individuals or pairs may roost throughout the active season behind the shutters of residences and seek shelter for hibernation in more protected spaces in the same or neighboring buildings or in caves in the winter. Fairly large colonies may inhabit the false fronts of shops or store buildings of an architectural style popular 50 years ago. The house bat is urban as well as rural in its choice of residence.

In view of the findings reported here, *Histoplasma* should be sought in soil samples adjacent to any buildings infested or colonized by bats in towns where histoplasmin sensitivity is observed under circumstances not readily explained by known exposures to the litter of chicken houses or other commonly recognized sources. It should be sought in towns where there is a differential histoplasmin-reactor rate, especially if the higher incidence of reactors is in an older part of town. Large old houses, even if in good repair, offer more crevices and shelters for bats than the small compact houses of new real estate developments.

This remarkable association of bats with a severe family epidemic of histoplasmosis and with the presence of *Histoplasma* adjacent to the foundation of the house may not be unique. Enrichment by bat feces of soil near a building infested by the house bat appears to be as effective in supporting the saprophytic growth of *Histoplasma* as bat guano is generally supposed to be in those caves associated with cases

of histoplasmosis. The wide distribution of the house bat and its intimate association with man and human dwellings may well support a widespread reservoir of *Histoplasma* in soil to which man is frequently exposed.

Summary

Histoplasma capsulatum was isolated from 50 of 105 soil samples from 6 collections made between October 1956 and September 1957 on the premises where a family epidemic of histoplasmosis had occurred. Chickens, often associated with the saprophytic growth of this fungus, had not been kept on the premises for many years.

Histoplasma was isolated from 45 of 66 soil specimens (68 percent) taken adjacent to or within 5 feet of the foundation wall of the house and from only 2 of 29 (6.8 percent) taken 6-18 feet from the house. Three of ten samples taken near a doghouse were also positive.

The house sheltered a colony of the brown, or house, bat (*Eptesicus fuscus*), and bat dung was found adjacent to the foundation. The presence of bats is the apparent factor responsible for the constant saprophytic infestation of soil on these premises with *H. capsulatum*.

The house bat inhabits suitable shelters in towns and cities, as well as rural areas, and may be the ecologic factor responsible for the presence of *Histoplasma*, prevalent histoplasmin sensitivity, and clinical histoplasmosis in observed instances of urban histoplasmosis in towns and cities where reasons for the occurrence of these phenomena have not yet been determined.

Cerebrovascular Diseases Classified

All known types of brain "strokes" have been classified and defined for the first time in a 2-year study conducted by a committee appointed by the National Institute of Neurological Diseases and Blindness, Public Health Service. The committee, comprising eight of the Nation's leading physicians, was formed to explore ways of facilitating research in cerebrovascular diseases.

In addition to setting up a common language for the exchange of information of researchers, the classification serves as a useful tool in the treatment of "strokes." Precise diagnosis is imperative in new treatments for several types of brain blood vessel diseases, the study points out.

Nine major categories are set up in the classification, with changes in tissue the determining factor in the groupings. Two categories include the majority of cases: blocks in a blood vessel and rupture or hemorrhage of a blood vessel. Next important is temporary lack of blood without tissue death.

In emphasizing the pioneering character of the study, Dr. Clark H. Millikan, neurologist of the Mayo Clinic, Rochester, Minn., and committee chairman, said that many statements in the study may undergo modification as understanding of the diseases increases.

Copies of the study, A Classification and Outline of Cerebrovascular Diseases, which appeared in the May 1958 issue of *Neurology*, may be obtained from the National Institute of Neurological Diseases and Blindness, Public Health Service, Bethesda 14, Md.

Decreasing Radiation In Photofluorography

EDWARD L. ERNSBERGER

DURING the last several years, considerable attention has been given to reducing the amount of diagnostic X-radiation that medical and dental patients receive. With this objective, research has concentrated on the radiographic process, making improvements in intensifying screens and film emulsions, to reduce exposure of both film and patient without loss of detail of the diagnostic picture.

A major consideration is that up to 98 percent of the density of a radiograph, except for the nonscreen type of film, may result from the actinic rays given off a fluorescent screen under the influence of X-ray energy. The remaining density is a consequence of X-rays directly. In photofluorographic work, the radiograph is obtained by a purely photographic process. A camera records on photographic film the image appearing on a chemically treated surface that fluoresces under the influence of X-radiation.

The period of film exposure required to obtain an image by this photographic procedure determines the necessary period of X-ray production. Therefore, shortening the necessary photographic exposure time, by use of a "brighter" fluorescent screen or a more sensitive film emulsion to record the image, permits corresponding reductions in X-ray exposure time for the patient and in the amount of scattered radiation the technician and others in the vicinity of the X-ray machine will absorb.

Faster Film Emulsions

Within the last few months, a new green-sensitive photofluorographic film (A), type PFG-470, which has a faster emulsion than film produced previously (A), type PF-470,

has been put on the market. This new film was tested in the Electronics and Technical Service Laboratory, Tuberculosis Program, Public Health Service, to compare its emulsion speed with that of the earlier type.

Both types of film were exposed on a 70-mm. photofluorographic X-ray machine, using a safety-timer instead of a phototimer. An impulse counter (one impulse being equal to $\frac{1}{120}$ second) was connected across the field coil of the main contactor to measure the time of each exposure. A Presdwood phantom, representing the patient, was used in front of the hood. The grid in front of the fluorescent screen was removed so that grid lines would not interfere in making density readings. The X-ray machine was operated at 100 kilovolts peak and 175 milliamperes. All factors, except time, were kept constant, and exposures were made on both types of film.

The two strips of film were processed simultaneously by the temperature-time technique in open tanks containing regular X-ray processing solutions. After the film was washed and dried, the density in the same area of each frame of film was measured by a densitometer. The base plus fog level density was measured in the clear area between each two frames and subtracted from the density reading in the frame to obtain the density of the emulsion. The emulsion density readings and the film density readings were then plotted against time periods in impulses, and smooth curves were drawn through the points for both types of film (fig. 1). By choosing a density reading and noting the corresponding exposure time on each curve, the comparative speeds of the two films were obtained.

It is noteworthy that the new film emulsion is twice as fast at the density of 1 as the older type. The older type has a colorless base in contrast to the light purple base of the new. This, of course, affects the overall apparent density and makes the new type of film 2.8 times faster than the old at the density of 1.

Less Radiation

Another study carried out in this laboratory determined the effect of added filtration on:

Mr. Ernsberger is an electronic scientist with the Electronics and Technical Service Laboratory, Public Health Service, Rockville, Md.

1. Skin dose received by a patient from a 70-mm. chest photofluorogram.

2. Exposure time.

The work was done in a bus unit containing a 70-mm. photofluorographic machine. All exposures were phototimed, and an impulse counter was connected across the field coil of the main contactor to measure the time in multiples of $\frac{1}{120}$ of a second. Again a Presdwood phantom was used. A condenser R meter with a 25-roentgen chamber was used to measure the radiation at the surface of the phantom, which represents the skin dose received by the patient. Pieces of half-hard-rolled aluminum sheet, 0.025 inches thick, were used for the added filtration.

X-rays were produced at 100 kilovolts peak and 175 milliamperes, first with no added filtration, then with added filtration, in steps of 0.025 inch. The observed data are graphed in figure 2. An increase in the period of exposure is required with increased filtration to obtain a given density; radiation experienced by the phantom in the direct beam decreases, neverthe-

Figure 1. Comparison of speed of two types of photofluorographic film (100 kilovolts peak, 175 milliamperes).

Figure 2. Effect of aluminum filtration on exposure time and radiation dose.

less. With 3 mm. of added aluminum filtration, the phantom received only 55 percent of the dose received without such filtration even though the length of exposure increased 30 percent. The aluminum filters out those X-rays of longer wave length which are absorbed by the patient and do not contribute to the brightness of the fluorescent screen.

Summary

A new type of photofluorographic film (PFG-470) requires an exposure period only half as long as the earlier type (PF-470) to obtain a radiograph of the same density. Thus, the patient receives only one-half the radiation. If 3 mm. of aluminum filtration is added, the patient will receive approximately half the radiation dose he would receive without it, with either type of film, even though the exposure time must be increased a third to obtain an image of a given density.

To illustrate these reductions, for a fluorogram of a patient of average size made with the earlier type of film and no added filtration (100 kilovolts peak and 175 milliamperes), the exposure time may be 18 impulses, or 0.15 seconds. If 3 mm. of aluminum filtration is added

Decreasing Radiation In Photofluorography

EDWARD L. ERNSBERGER

DURING the last several years, considerable attention has been given to reducing the amount of diagnostic X-radiation that medical and dental patients receive. With this objective, research has concentrated on the radiographic process, making improvements in intensifying screens and film emulsions, to reduce exposure of both film and patient without loss of detail of the diagnostic picture.

A major consideration is that up to 98 percent of the density of a radiograph, except for the nonscreen type of film, may result from the actinic rays given off a fluorescent screen under the influence of X-ray energy. The remaining density is a consequence of X-rays directly. In photofluorographic work, the radiograph is obtained by a purely photographic process. A camera records on photographic film the image appearing on a chemically treated surface that fluoresces under the influence of X-radiation.

The period of film exposure required to obtain an image by this photographic procedure determines the necessary period of X-ray production. Therefore, shortening the necessary photographic exposure time, by use of a "brighter" fluorescent screen or a more sensitive film emulsion to record the image, permits corresponding reductions in X-ray exposure time for the patient and in the amount of scattered radiation the technician and others in the vicinity of the X-ray machine will absorb.

Faster Film Emulsions

Within the last few months, a new green-sensitive photofluorographic film (A), type PFG-470, which has a faster emulsion than film produced previously (A), type PF-470,

has been put on the market. This new film was tested in the Electronics and Technical Service Laboratory, Tuberculosis Program, Public Health Service, to compare its emulsion speed with that of the earlier type.

Both types of film were exposed on a 70-mm. photofluorographic X-ray machine, using a safety-timer instead of a phototimer. An impulse counter (one impulse being equal to $\frac{1}{120}$ second) was connected across the field coil of the main contactor to measure the time of each exposure. A Presdwood phantom, representing the patient, was used in front of the hood. The base plus fog level density was measured in the clear area between each two frames and subtracted from the density reading in the frame to obtain the density of the emulsion. The emulsion density readings and the film density readings were then plotted against time periods in impulses, and smooth curves were drawn through the points for both types of film (fig. 1). By choosing a density reading and noting the corresponding exposure time on each curve, the comparative speeds of the two films were obtained.

It is noteworthy that the new film emulsion is twice as fast at the density of 1 as the older type. The older type has a colorless base in contrast to the light purple base of the new. This, of course, affects the overall apparent density and makes the new type of film 2.8 times faster than the old at the density of 1.

Less Radiation

Serologic Studies of Staphylococcal Enterotoxin

E. P. CASMAN, Ph.D.

THE NEED for a simple and specific technique for demonstrating and assaying staphylococcal enterotoxin has been recognized for a long time. Research efforts ranging from biological tests with small and relatively cheap animals (1, 2) to extensive chemical and serologic studies of enterotoxin (3) have not attained this important objective.

The many contradictory reports found in the literature (4) on staphylococcal enterotoxin are evidence of the inadequacy of the crude, difficult, and impractical tests that are available for its detection. Evidence incriminating suspected foods in outbreaks of staphylococcal food poisoning is largely circumstantial and is limited to the use of epidemiological findings and the demonstration of the presence in the suspected food of appreciable numbers of enterotoxin-producing staphylococci. The very ubiquity of the staphylococcus and, conversely, the possibility of the presence of the heat-resistant enterotoxin in foods which no longer contain viable staphylococci, detract considerably from the value of such procedures.

Furthermore, the demonstration of enterotoxigenicity of the isolated staphylococcus involves considerable effort. The isolated organism must be cultured on special media in order to produce the enterotoxin, and the presence of the latter is determined by the feeding of monkeys or the parenteral introduction of the culture filtrates into monkeys or cats. When available, human volunteers may be fed

the suspected food or the culture filtrate. Monkeys, cats, and humans vary considerably in their susceptibility to the enterotoxin and may acquire an increased tolerance to it. Prior to parenteral administration of the culture filtrate it is necessary to remove or neutralize the alpha or beta hemolysins which may be present. These toxins are lethal and may in themselves elicit the emetic reaction characteristic of the enterotoxin. The monkey-feeding test, although specific, is impractical because of its low sensitivity, the marked variation in susceptibility of the animals, and obvious problems of their cost, availability, handling, and maintenance.

Parenteral administration of the enterotoxin to cats is complicated by the activity of the alpha and beta hemolysins, by rapid production of increased tolerance to the enterotoxin, and by a considerable variation in susceptibility of test animals. This method is, however, more sensitive, cheaper, and more convenient than the monkey-feeding test. In the studies presented here, 3 to 10 ml. of culture filtrate was injected intravenously into unanesthetized adult cats, as described by Hammon (5). Prior to injection, alpha and beta hemolysins were removed by boiling, neutralization with antiserum containing antibodies for alpha and beta hemolysins, or by digestion with pancreatin (unpublished data). The cats were used once only.

Key strains of staphylococci, selected for the production of enterotoxin for immunization purposes, were checked for enterotoxigenicity by feeding culture filtrates to monkeys.

The studies described here were designed to

with this type of film, the patient will receive only half as large a dose of radiation although the exposure time will be increased to 24 impulses, or 0.20 seconds. If the new film is used, which simultaneously halves both the exposure time and the dose, an exposure of 12 impulses, or 0.10 seconds, will suffice, and the

radiation dose will be only one-fourth of that received with the older type of film without the added filtration.

Health Survey in Nepal

Our bureau of local health services has finished its first health survey, reporting on 157 persons in Hitura, Nepal, in territory described as "Paradise" in a recent travel movie. In the last 5 years, deaths occurred in 20 of the 30 families surveyed; 7 of the deaths came before 1 year of age and 13 before the age of 20.

The 34 women questioned in the survey had had 9 abortions or stillbirths and 142 deliveries of live babies; but 18 of these infants died before the age of 1 year. These figures mean an annual mortality rate of more than 4,000 per 100,000 or 4 per 100 population. This rate cannot be projected because of the small sample, but Hitura's mortality rate may possibly represent all of rural Nepal.

First Conference

Thailand's first national conference of public health workers was held at Chonburi in March 1957. From all parts of the country, 200 health officers, nurses, sanitary engineers, health educators, and other workers gathered to confer, review, and plan for the nationwide public health program.

Cochabamba's Boycott

The 100,000 people of Cochabamba were vaccinated in 7 days when smallpox broke out in this Bolivian city. Health service workers found 218 cases, but it is assumed that many others were hidden and that some infected persons left to escape isolation.

In a mass campaign 24 teams of medical students vaccinated house by house, 5 teams of nurses vaccinated at schools and factories, and 16 vaccination clinics were set up at government and private agencies and in industrial plants. Cochabamba's 29 pharmacies were given instructions and equipment for inoculations.

Local authorities and the public joined in a voluntary boycott which was decisive in the campaign's success. Banks, restaurants, buses, cinemas, and public offices refused to serve unvaccinated persons.

Glycerinated smallpox vaccine previously used in Bolivia proved to be of doubtful potency; several persons vaccinated a month before developed the disease during the outbreak. Lyophilized vaccine was imported from France and Peru for the mass vaccinations.

At the close of the campaign, 105,548 people—including both the resident and floating population—had been vaccinated. These were identified by indelible ink marks on the finger tip, which helped to establish the number inoculated.

As the campaign extends to rural areas of Cochabamba Department and later to the rest of the nation, it is expected that smallpox will be wiped out in Bolivia.

the same medium which had been incubated for 20 to 24 hours with rocking or rotation.

Separation and Concentration

It was necessary to concentrate and partially purify the crude toxin before use in attempts to immunize rabbits and in the serologic studies described below. This was accomplished briefly as follows: After removal of the organisms by centrifugation and filtration through a Selas candle, the filtrate was reduced in volume approximately 100 times by dialysis and concentration. Dialysis was carried out for 2 or 3 days at 5° C. against distilled water containing 1:1,000,000 merthiolate. Concentration was then accomplished by preevaporation in a current of air or by the use of a flash evaporator.

Some of the larger volumes of culture filtrate were partially purified and concentrated by first adjusting the pH to 3.2–3.3 at 0° C. with 1:5 HCl to precipitate a considerable amount of nonenterotoxic material and then precipitating most of the enterotoxin from the supernatant by slowly adding methanol to a final concentration of 25 percent while maintaining the temperature at –5° C. or lower.

In some of the immunization studies in which toxins prepared with enterotoxic staphylococcus strains No. 224 and No. 230 were used, digestion with crystalline trypsin was found to remove the hemolysins without appreciable destruction of the enterotoxin. After such treatment, however, it was necessary to increase the concentrations of methanol to 40 to 65 percent in order to precipitate the enterotoxin.

The crude concentrates obtained by these procedures varied considerably in potency, containing from 200 to 1,000 cat-vomiting doses per milliliter. A cat-vomiting dose is the minimal amount of enterotoxin which consistently produces emesis in cats. This is determined by injecting intravenously twofold serial dilutions into healthy cats.

The availability, later, of enterotoxins of higher potencies permitted a considerable acceleration in the progress of the present study. These were concentrates of toxins of strains 196E and S6 obtained through the courtesy of Dr. G. M. Daek. The toxins had been pro-

duced in a protolysate medium (10) and the dry S6 preparation had been considerably purified, using procedures described by Bergdoll (3). The crude 196E concentrates contained appreciable amounts of alpha and beta hemolysins and varied in potency, having a dry weight of from 10 to 90 µg. per cat-vomiting dose. The partially purified S6 preparation contained a small amount of alpha hemolysin and no beta hemolysin and consistently produced emesis in cats with as little as 2 µg. dry weight.

Demonstration of Antigenicity

In the exploratory stages of this phase of the study, immunization of rabbits was carried out over a long period of time, using as antigen trypsin-digested concentrates of No. 224 enterotoxin prepared in a variety of ways and injected at variable dosages both intravenously and subcutaneously. Rabbits were found to possess a marked though variable susceptibility to enterotoxin. When the intravenous route of injection was employed, some rabbits were killed in 12 to 24 hours by 1 or 2 cat-vomiting doses. It was necessary, therefore, to build up resistance to the enterotoxin gradually. One or two cat-vomiting doses in 1 or 2 percent alum were repeatedly injected intracutaneously or subcutaneously, or both, until a tolerance to the intravenous injection of approximately two vomiting doses of the enterotoxin was established. The amount of antigen was then increased and injected subcutaneously. The intervals between injections were adjusted according to the animal's maintenance of weight. In later stages of the immunization, in which larger amounts of antigen were used, the alum content was increased to 10 percent and the antigen was administered subcutaneously in divided doses. All alum-containing antigens were adjusted to a final pH of 6.0 and were preserved with 1:10,000 merthiolate.

Antigens prepared with 196E concentrates or with the partially purified S6 enterotoxin were not subjected to tryptic digestion. Both potassium alum and Freund's adjuvants (emulsion of 2 parts of antigen dissolved or suspended in saline, 1 part Falba, and 1 part paraffin oil, with 0.02 percent killed human

determine the possible value of serologic procedures for the development of a practical test for staphylococcal enterotoxin and were carried out in the following sequence: (a) production of enterotoxin in a simply prepared and dialyzable fluid medium; (b) separation and concentration of the enterotoxin for purposes of immunization and serologic testing; (c) demonstration of antigenicity by the passive transfer of immunity and by *in vitro* neutralization of enterotoxin, using serum from immunized rabbits; and (d) demonstration of an antigen common to enterotoxin-containing culture filtrates and absent in culture filtrates known not to contain enterotoxin.

Production of Enterotoxin

Since staphylococcal enterotoxin is produced in relatively small amounts, it was felt essential that a culture medium be used from which the products of bacterial growth could be easily separated. To this end, a medium was sought which was dialyzable, free from lipids, proteins, and carbohydrates, and capable of supporting good staphylococcal growth and toxin production.

Alpha hemolysin rather than enterotoxin productivity was studied in the early development of the medium, and later the adequacy of the medium for the production of enterotoxin was determined by comparison with preparations made in Dolman and Wilson's soft agar medium (6). Aeration by rocking (7) or rotation (8) of shallow fluid cultures in an atmosphere of 40 percent carbon dioxide and 60 percent oxygen was employed in this portion of the study.

Favorite and Hammon (8) suggested the use of a simple medium for the production of enterotoxin, consisting of a hydrolysate of casein enriched with glucose, nicotinic acid, and thiamine. To obtain good growth and toxin production, they found it necessary to inoculate the medium rather heavily with a culture prepared in a meat infusion peptone broth, thus supplying additional growth factors but at the same time introducing complex organic substances. In our hands this medium and procedure failed to give consistently good yields of either alpha hemolysin or enterotoxin.

When a commercially prepared acid hydrolysate of casein (Difco's Casamino acids) was employed, it was found that in order to obtain very good growth of staphylococci it was necessary to add calcium pantothenate, l-cystine, tryptophane, and magnesium sulfate in addition to glucose, nicotinic acid, and thiamine. To obtain good production of alpha hemolysin, it was found necessary to substitute sodium acetate for the glucose and to add an optimal amount of iron. The following formula, which was found to be best for growth and the production of alpha hemolysin, consistently supported the production of enterotoxin.

	Gram
Ferric citrate.....	0.025
K ₂ HPO ₄	1.0
KH ₂ PO ₄	1.0
MgSO ₄ · 7H ₂ O	0.2
l-cystine	0.025
Sodium acetate.....	7.0
l-tryptophane	0.075
Casamino acids (Difco).....	20.0
	Microgram
Calcium pantothenate.....	500
Thiamine hydrochloride.....	40
Nicotinic acid.....	1,200
	Liter
Distilled water.....	1

The pH was adjusted to 7.2-7.4 by the addition of approximately 1.0 ml. of 10 N sodium hydroxide, and the medium was sterilized by autoclaving at 121° C. for 15 minutes after distribution in the final container. Inoculums were small (0.1 ml. of an 18- to 24-hour broth culture) for 30- to 100-ml. quantities of medium and no special atmosphere was required. The method of aeration varied with the volume of toxin desired. The rotation at 20 rpm of 30-ml. quantities of the culture in 8-oz. nursing bottles (8), the rocking (7) of 100-ml. quantities in Roux bottles through an arc of 20° each 1½ seconds, and the sparging of air through larger volumes (9) all proved satisfactory. While enterotoxin was produced in all three procedures after 24 hours, rotated or rocked cultures were harvested after 30 to 48 hours of incubation at 35°-37° C. Larger volumes of culture were aerated by sparging with filtered air for 20 to 24 hours after inoculating with approximately one-tenth volume of a culture in

Figure 1. Zones of precipitation after absorption of anti-S6 serum with Wood 46 and No. 1 concentrates and an extract of No. 243 organisms. Illustrating the formation of a "line of identity" (the coalescence of lines D and B) and a "line of nonidentity" (the intersection of lines D and C). Evident also is the antigen excess effect obtained with the concentrated culture filtrate of strain No. 1 which, in addition to failing to produce a zone of precipitation, prevents the complete development of line B.

ence of a distinguishing antigen common to enterotoxigenic strains might permit the development of a test for the detection and assay of this toxin. A slight modification of the Petri-dish agar diffusion method of Ouchterlony (14, 15) for the qualitative analysis of soluble antigens and antibodies was used for this purpose.

In Ouchterlony's method, antiserum is added to a centrally located well in the agar and antigens are added to peripheral wells. Antigens and antibodies diffuse toward each other through the agar to form zones or lines of precipitation where the two combine in optimal proportions. The method permits separation of multiple precipitation systems into their individual components and, in addition, permits the comparison of two antigens or antibodies with each other in order to establish their identity, partial identity, or nonidentity (fig. 1).

In our study, plates were prepared with a base containing 1.6 percent Noble Special Agar (Difco), 0.8 percent NaCl, 0.01 percent merthi-

olate, 0.003 percent methyl orange, and M/25 veronal. The mixture was melted, adjusted to pH 7.4 and filtered through paper until clear. A central well and four peripheral wells were prepared using rectangular aluminum blocks, measuring 8 mm. square in cross section. A central hole, measuring 2 mm. in diameter was bored through the length of each block to facilitate its removal from the solidified agar. The wells were prepared by covering the bottom of a standard Petri dish with 10 ml. of the agar. After solidification, the blocks were placed in position and an additional 20 ml. of the agar was added and allowed to solidify. The blocks were carefully removed from the agar and arranged as recommended by Wilson and Pringle (16), with a distance of 7 mm. between the central serum-containing well and the peripheral antigen-containing wells. The plates were allowed to remain uncovered for 30 to 60 minutes at 35° C. prior to use. The wells were charged with 0.2 ml. quantities of the reagents and were not refilled. Results were recorded after 5 to 8 days at room temperature.

The S6 antiserum was found to contain antibodies for antigens possessed by both enterotoxigenic strains and nonenterotoxigenic strains of staphylococcus. It appeared necessary, therefore, to remove most of the antibodies for these common antigens before attempting to demonstrate the presence of an antigen peculiar to enterotoxigenic preparations and absent from those that were enterotoxin free.

To attain this goal, anti-S6 serum was first absorbed with concentrated filtrates of enterotoxin-negative strains Wood 46 and No. 1. Both strains gave negative tests for enterotoxin when injected into cats in amounts equivalent to 50-60 ml. of crude culture filtrate. The Wood 46 strain was obtained from the Connaught Laboratories, Toronto, Canada, in 1938. It is coagulase-positive, produces an appreciable amount of alpha hemolysin, and has also been found to be nonenterotoxigenic by other investigators. Strain No. 1 was isolated in 1949 from the stomach contents of an infant who succumbed to what appeared to be staphylococcal food poisoning. This strain differed from nonenterotoxigenic strains and resembled enterotoxin-producing strains in that it contained heat-stable antigen which was precipitated by anti-

tubercle bacilli and preserved with 1:10,000 merthiolate) were used in the preparation of 196E antisera (11). For the preparation of anti-S6 sera, only Freund's adjuvants were employed.

Sera were obtained from the rabbits under immunization from time to time and tested for their antienterotoxin content either by preliminary mixture with approximately 2 vomiting doses of homologous enterotoxin (neutralization) 1 or 2 hours before injecting cats or by their ability to produce in cats a passive immunity (protection) to approximately 2 vomiting doses of enterotoxin. In the latter procedure the intravenous injection of the serum was followed within 3 to 5 minutes by injection of the challenging dose of enterotoxin. The amount of serum required to demonstrate neutralization or protection varied with the rabbit source, the duration of the immunization procedure, and the potency and adjuvant composition of the enterotoxin antigen.

With the more potent enterotoxins 196E and S6 it was possible to demonstrate the production of "protective" antienterotoxin in a relatively short period of time after tolerance to the enterotoxin had been produced by the repeated intracutaneous, subcutaneous, and intravenous injection of 1 or 2 vomiting doses. For example, a rabbit prepared in this fashion could be injected subcutaneously with 1,000, 2,000, and 3,000 vomiting doses of 196E in 10 percent alum at 14-day intervals. Protection against 2 vomiting doses of the homologous enterotoxin was demonstrated with 0.3 ml. of serum obtained 10 days after the final injection of the antigen. Another similarly prepared rabbit was immunized with 25, 125, 250, and 375 vomiting doses of S6 antigen containing Freund's adjuvants. Protection against two vomiting doses of the homologous enterotoxin required the use of 0.8 ml. of serum obtained 30 days after the final injection of antigen. As little as 0.08 ml. of an anti-196E serum was found to confer a passive immunity against its homologous enterotoxin. In most instances, however, 0.3 to 0.5 ml. of serum was required to produce this effect.

The results of more than 65 tests, representing repeatedly confirmed observations, are summarized in the table. Results obtained with

serum fractions prepared according to the procedures of Nichol and Deutsch (12) and Aladjem and Lieberman (13) are included. Quantitative determinations of the antienterotoxin content of the antisera were not made. In no instance, however, was more than 0.5 ml. of the serum fraction, or its equivalent of whole serum, used. The antigenicity of the enterotoxins from the three staphylococcus strains, Nos. 224, 196E, and S6, is clearly demonstrated. All react with their homologous enterotoxins, and 196E antiserum protects against heterologous S6 and 230 enterotoxins. Pseudoglobulin as well as the globulin fractions of Nichol and Deutsch prepared from 196E antisera neutralized 196E enterotoxin and protected cats challenged with 196E and 230 enterotoxins.

Demonstration of a Common Antigen

With the production of sera containing antibodies for homologous and for heterologous enterotoxins, an attempt was made to reveal a serologic relationship between enterotoxin from different strains of staphylococcus. It was felt that the establishment of the serologic identity of staphylococcal enterotoxin or the pres-

Neutralization of enterotoxins by rabbit antisera and passive transfer of immunity as determined by the intravenous test on cats

Figure 3. Effect of further absorption with either a concentrated culture filtrate of strain No. 243 (left) or an extract of No. 243 cells (right). Both absorbing antigens remove the heavy line of interference seen in figure 2. Absorption with the cell extract, however, removes less of the antibody which produces the single line with 196E and the more peripheral (line B, right) of the two lines produced with S6 antigen. The nonenterotoxigenic Wood 46 and No. 227 antigens produce no lines.

figures 2 and 3. The interference line of S6 was removed and only one good line of precipitation was formed with the heterologous 196E toxin. The outer of the two remaining lines formed with the homologous S6 toxin (line B, figs. 1 and 3) could be identified with the single sharply defined line formed with 196E toxin by placing these antigens in adjacent wells to produce clear-cut lines of precipitation which coalesced at the junction of the respective precipitation lines (fig. 1).

The absorbed S6 serum was used finally, to test 100-fold concentrations of culture filtrates of 21 strains of staphylococcus which had been found to be enterotoxigenic by the cat test and 6 enterotoxin-negative strains for their ability to produce "lines of identity" with 196E and S6 toxins. Of the 21 enterotoxigenic strains, 16 were isolated from foods epidemiologically incriminated in food poisoning incidents. Two were isolated during routine examination of foods not involved in food poisonings. Two were isolated from feces from patients with enteritis following intensive antibiotic therapy, and one (No. 244) from the nose of a child.

Typical results obtained with some of the culture filtrates are shown in figure 4. All but one of the enterotoxigenic strains gave lines of

identity with both toxins. The one exception, No. 244, was not a food poisoning strain but was isolated from the nose of a child. This strain gave a positive cat test for enterotoxin shortly after isolation, but, when retested, was found to have lost this ability. Of the 6 enterotoxin-negative strains, 5 produced no lines of any kind. The sixth, however, produced a well-defined line of identity with the two positive controls. This strain, No. 260, had been isolated during routine bacteriological examination at the New York City Department of Health Laboratories from crab meat which was not involved in a food poisoning incident.

The antigenic component common to the 21 enterotoxigenic strains is shared by strains No. 260 and No. 1, both of which are apparently nonenterotoxigenic. Strain No. 1 produces this antigen in relatively large amounts. This was shown by an antigen-excess effect when its concentrated culture filtrate was used in the Ouchterlony plate test. It failed to form its portion of the line of identity and also inhibited the development of the portion produced by the enterotoxigenic control (line B in fig. 1). Furthermore, the antibody in the absorbed serum responsible for the production of the lines of identity was present in small amount and could

Figure 2. Effect of absorption of anti-S6 serum with concentrates of culture filtrates of strains Wood 46 and No. 1. Many of the precipitation systems produced with unabsorbed serum (left) are not obtained with the absorbed serum (right). Detection of coalescence of lines produced by heterologous 196E and No. 230 enterotoxins with one produced by the S6 antigen-antibody system is interfered with by heavy line A.

enterotoxin serum absorbed with a concentrated culture filtrate of the Wood 46 strain.

The effectiveness of the absorption procedures was determined by preparing Ouchterlony plates to demonstrate coalescing lines of precipitation (lines of identity) between S6 and 196E (see fig. 1) enterotoxins and the absence of such lines in the antigens used for absorption. For this purpose, the peripheral wells were charged with 100-fold concentrates of culture filtrates of the Wood 46 and No. 1 staphylococcus strains and with 2 to 4 cat-vomiting doses of S6 and 196E enterotoxins. Undiluted absorbed serum was placed in the central well.

Although absorption with the Wood 46 and No. 1 antigens removed much of the antibody in the serum (fig. 2), demonstration of a "line of identity" belonging only to the S6 and 196E toxins was not possible. This was due (a) to the possession by the No. 1 strain of staphylococcus of an antigen which was common to the enterotoxigenic strains although not found in the other nonenterotoxigenic strains under study, and (b) to the presence in the anti-S6 serum of an antibody which was not sufficiently absorbed by the Wood 46 and No. 1 concentrates so that a heavy masking zone of precipitation was produced in the Ouchterlony plate with S6 enterotoxin (fig. 2, right).

Culture filtrates of enterotoxigenic strain No. 243 differed from others under study in that, like the S6 enterotoxin, they produced a heavy masking zone of precipitation with the absorbed anti-S6 serum. Further absorption of the serum with a glass bead extract (17) of the cells of strain No. 243 removed the masking antibody. The cell extract rather than a concentrated culture filtrate was employed because of the presence of a smaller amount of enterotoxin in the cell extract. Assay for enterotoxin by injecting cats and for "interfering antigen" by titration with the Wood 46 strain No. 1-absorbed anti-S6 serum showed that the concentrated culture filtrate contained 7 times more interfering antigen but 30 times more enterotoxin than did the cell extract. Absorption of the absorbed serum with the extract of the No. 243 cells resulted in the production of a good, well-defined line of identity between the undiluted absorbed serum and S6 and 196E enterotoxins. Use of the more toxic concentrate of the culture filtrate of strain 243 instead of the cell extract for this purpose resulted in the production of a markedly less well-developed line of identity (fig. 3).

The effects of absorption with the enterotoxin-negative Wood 46 and No. 1 strains and with the No. 243 preparations are presented in

line with the heterologous 196E enterotoxin in the agar diffusion plate test (fig. 5).

The presence, in strains No. 1 and No. 260, of the antigen otherwise common only to enterotoxigenic strains, suggested the possibility that the use of other culture media and procedures might reveal their enterotoxigenicity. Cultivation of these strains in a mixture of 40 percent carbon dioxide and 60 percent oxygen instead of air and on Dolman's soft agar has yielded negative results. Attempts to demonstrate in the products of growth of these strains a protoxin similar to those described for some of the clostridial toxins (18-20) have yielded essentially negative results. In addition, attempts passively to protect cats against S6 enterotoxin with antiserum prepared against concentrated culture filtrates of strain No. 1 have also been unsuccessful, further indicating that the "common antigen" is neither toxin nor protoxin.

Discussion

The work of Dolman and Wilson (21) contributed substantially to the direction of the studies presented here. Using antiserum produced in a horse, they were able to demonstrate a specific flocculation reaction which appeared to involve the enterotoxin and its homologous antibody. They indicated the desirability of support of their findings with many flocculation tests performed "in conjunction with parallel kitten tests, and involving filtrates derived from a large number of strains."

The absence of such confirmative studies, in the light of present knowledge, would seem to be attributable to the difficulties involved in the production of a specific antiserum of sufficient potency and the necessary dependence on one or more of the inadequate tests for the enterotoxin. The presence of not more than 5 percent enterotoxin in the purest preparations so far prepared by Bergdoll (22) and the consistently positive emetic responses obtained in the present work with 2 μ g. of the partially purified S6 enterotoxin suggest a possible explanation for earlier failures to confer passive immunity (5, 23), since in these studies antisera were produced by immunization with relatively weak and crude preparations. In

addition, inability to obtain an active immunity to heterologous enterotoxins in monkeys (24) and in cats (25) may have discouraged such studies.

Conflicting reports as to the antigenicity of staphylococcal enterotoxin (5, 6, 23, 26, 27) indicated the need for studies designed to resolve this important phase of the problem. Although repeated demonstrations of the production of an acquired immunity or "increased tolerance" to enterotoxin had been made, the evidence for passive transfer of immunity was lacking.

Neutralization of enterotoxic preparations, however, had been reported. Dolman, Wilson, and Cockcroft (28) found that the serum from a kitten made resistant to enterotoxin neutralized the enterotoxin when a mixture of the two was injected into a normal kitten. Davison, Dack, and Cary (29) confirmed this report when the mixtures were injected intraperitoneally. When the intracardial route of injection was used in kittens, or the intravenous route in monkeys, there was no neutralization by the serum, they reported. They also stated: "When normal kitten blood was added to a mixture of enterotoxic filtrate and antiserum and then injected intraperitoneally into normal kittens, protection was not assured." These investigators concluded that the presence of whole blood, extravascularly or intravascularly, prevented the neutralization of enterotoxin by its antiserum. Dolman (27), however, demonstrated neutralization of enterotoxin by serum from immunized human and animal sources by injecting enterotoxin-serum mixtures intravenously into cats. Hammon (5), working with crude toxins, failed to demonstrate *in vivo* neutralization through the use of "hyperimmune" sera from cats and rabbits. Surgalla, Bergdoll, and Dack (30) were able to demonstrate a neutralization of S6 enterotoxin after mixing the toxin with the homologous rabbit antiserum and feeding the mixture to monkeys. More recently, Burbianka (31), administering enterotoxin and antiserum to cats by the intravenous route, claimed to have neutralized a minimal enterotoxic dose of enterotoxin with as little as 0.005 ml. of an antiserum produced in rabbits. Antiserum, produced against enterotoxin derived from one strain of staphylococcus neu-

Figure 4. Examples of coalescing zones of precipitation ("lines of identity") formed between enterotoxigenic (designated with a plus sign) culture filtrates and the two control enterotoxins (S6 and 196E). Left: The line of precipitation produced with enterotoxigenic culture filtrate of strain No. 236 coalesces with the single 196E line and with the outer (line B) of the two lines produced by the S6 enterotoxin. The nonenterotoxigenic No. 244 produces no lines. Right: The line of precipitation produced with enterotoxigenic culture filtrate of strain No. 258 coalesces with the single 196E line and with the outer (line B) of the two lines produced by the S6 enterotoxin. The nonenterotoxigenic No. 259 produces no lines.

be removed completely by further absorption with the strain No. 1 concentrate. It was apparent, therefore, that it would be desirable to eliminate the use of this antigen for absorption of the anti-S6 serum.

Use of diluted anti-S6 serum after absorption with Wood 46 cells alone was subsequently found to be a better procedure for the procurement of an absorbed serum with which to demonstrate the antigenic component common to the 21 enterotoxigenic and 2 nonenterotoxigenic preparations. Wood 46 organisms removed from air-sparged culture by filtering and centrifuging were suspended in saline to give a heavy suspension, cooled to 4° C., and poured into 15 volumes of acetone at about -20° C. After standing overnight at -15° to -20° C., the acetone was removed and the cells were washed three times by suspending in acetone at -15° C. and centrifuging at -10° C. The organisms were then dried under vacuum and over CaCl₂ and stored at 5° C. Absorption of anti-S6 serum with acetone-dried Wood 46 cells was carried out by adding 10 percent (W/V) of the dried organisms to the serum, shaking until a uniform suspension was obtained, incubating at 37° C. with occasional shaking during a period of 2 to 3 hours, and placing at 5° C. overnight. The cells were removed by centrifuging

at 20-25° C. and washed with enough saline to adjust the absorbed serum to its original volume. The serum was absorbed a second time in the same manner and examined in order to determine the dilution giving a sharp

Figure 5. Effect of diluting anti-S6 serum (in peripheral wells) after absorption with Wood 46 cells, on the definition of the single line produced with the heterologous 196E enterotoxin (in central well). Use of a 16-fold dilution of the absorbed serum results in the production of the most sharply defined line (line E).

John K. Hoskins, 1884-1958

John K. Hoskins, who entered the Public Health Service in 1913 and became the Service's first chief sanitary engineer in 1943, died on May 16, 1958, in Chevy Chase, Md.

Mr. Hoskins served as Assistant Surgeon General of the Public Health Service from 1944 to 1947, when he retired from the Service.

As chief of an outstanding group of engineer-scientists, Mr. Hoskins directed stream pollution studies on the Ohio River in the early decades of the century. The reports published by this group, classics in the field, include the original formulation of the basic law of the biochemical oxygen demand reaction and the "oxygen sag" curve, and procedures for ascertaining the bacterial quality of water.

tralized the enterotoxin produced by other strains.

The evidence obtained with antigens prepared with S6, 196E, and 224 enterotoxins establishes conclusively the antigenicity of staphylococcal enterotoxin. The conferring of a passive immunity to cats injected successively with antiserum and challenging enterotoxin showed effective combination between the toxin and its antibody in the presence of whole blood.

The protection in cats obtained when 196E antiserum was challenged with heterologous 230 and S6 enterotoxins is of special interest in view of the conflicting report of Surgalla, Bergdoll, and Dack (24). These investigators, using the monkey-feeding test, found that monkeys possessing an active immunity to 196E enterotoxin were susceptible to S6 enterotoxin. The desirability of further work to demonstrate a passive immunity in the monkey when the challenging enterotoxin is given by mouth suggests itself. The possibility cannot be excluded, however, that differences in avidity or combining power of toxin and antitoxin or in the amounts of available antitoxin may be responsible for the conflicting observations. The short incubation period in staphylococcal food poisoning suggests the need for rapid neutralization of the enterotoxin.

The 21 "positive" culture filtrates appear to be serologically related and set apart from the 6 "negative" culture filtrates when examined by the agar-diffusion Petri dish method of Ouchterlony. The occurrence of the antigen common to the 21 enterotoxigenic strains in preparations obtained from 2 of 8 nonenterotoxigenic strains does not permit, at this time, the use of this antigen for the development of a reliable serologic procedure for the detection of enterotoxigenic strains. Should strains No. 1 and No. 260 eventually be found to be enterotoxigenic, more strains should be studied to establish the reliability of such a test. Furthermore, before the antigen can be identified with enterotoxin, a clear-cut demonstration of its enterotoxicity should be made.

Summary

A completely dialyzable fluid medium for the production of staphylococcal enterotoxin has been developed.

The antigenicity of staphylococcal enterotoxin and in vivo protection of cats against enterotoxin of heterologous and homologous strain origin has been demonstrated.

Of 29 strains of staphylococcus examined for enterotoxigenicity by the intravenous cat test 21 enterotoxigenic and 2 nonenterotoxigenic strains were found to be serologically related and set apart from the remaining 6 nonenterotoxigenic strains when examined by the agar diffusion test of Ouchterlony.

John K. Hoskins, 1884-1958

John K. Hoskins, who entered the Public Health Service in 1913 and became the Service's first chief sanitary engineer in 1943, died on May 16, 1958, in Chevy Chase, Md.

Mr. Hoskins served as Assistant Surgeon General of the Public Health Service from 1944 to 1947, when he retired from the Service.

As chief of an outstanding group of engineer-scientists, Mr. Hoskins directed stream pollution studies on the Ohio River in the early decades of the century. The reports published by this group, classics in the field, include the original formulation of the basic law of the biochemical oxygen demand reaction and the "oxygen sag" curve, and procedures for ascertaining the bacterial quality of water.

In this 2-year followup of a survey performed in an epidemic area of North American blastomycosis it was found that blastomycin skin sensitivity may be retained for at least 2 years in the absence of histoplasmin sensitivity or evidence of clinical blastomycosis.

Followup of Blastomycin Sensitivity in an Epidemic Area

J. GRAHAM SMITH, JR., M.D., WALTER C. HUMBERT, M.D., and SIDNEY OLANSKY, M.D.

TO GAIN more information about sensitivity to the blastomycin skin test and its relation to reactivity to the complement fixation test, a second survey in the area of Grifton in Pitt County, N. C., was conducted on May 21, 1956. Covering a sample of the persons found positive to the blastomycin skin test or the blastomycosis complement fixation test in the first survey in April 1954, it provides data on conversions and reversions.

The survey in April 1954 was instituted because of an epidemic of North American blastomycosis affecting 11 patients during the winter of 1953-54 in Grifton (1). It included 70-mm. chest X-rays, tuberculin, histoplasmin, and blastomycin skin tests, and blastomycosis

complement fixation tests. No cases of blastomycosis or histoplasmosis were discovered, although one case of active pulmonary tuberculosis was found.

Of the 1,648 persons surveyed in 1954, 2.9 percent were blastomycin sensitive and 6.4 percent were histoplasmin sensitive. There was no correlation of the blastomycosis complement fixation test with blastomycin skin sensitivity. Of the patients with positive blastomycin skin reactions, 4.7 percent had positive blastomycosis complement fixation tests, as opposed to 2.8 percent positive reactors in the total population tested, but 30.2 percent of the individuals with positive histoplasmin skin tests also had positive blastomycosis complement fixation tests, as opposed to only 6.4 percent in the total population.

These findings strongly suggested cross-reactions between the histoplasmin skin test and the blastomycosis complement fixation test. Unfortunately, histoplasmosis complement fixation tests were not done; it was therefore not possible to test the hypothesis that the correlation between the two might be explained by cross-reactions between the histoplasmosis and the blastomycosis complement fixation tests. On the basis of evidence from the 1954 survey it was believed that the sensitivity to both histoplasmin and blastomycin antigens in some

Dr. Smith, formerly at Duke University, is assistant professor in the division of dermatology, University of Miami School of Medicine. Dr. Olansky is associate professor, division of dermatology, Duke University School of Medicine. Dr. Humbert, who was the chief health officer, Pitt County (N. C.) Department of Health, died August 22, 1957.

This paper was presented in part before the American Academy of Dermatology and Syphilology, Chicago, December 10, 1956. It is a follow-up of an earlier study, an account of which appeared in the February 1957 issue of Public Health Reports, pp. 95-100.

individuals might be explained partly by a common mode of infection rather than a cross-reaction (2).

Since the 1954 survey, 5 more cases of blastomycosis have been diagnosed in the same county, and 4 of these patients lived within a 4-mile radius of Grifton at the time of onset of disease. (None of the 5 patients, however, had been included in the 1954 survey.) Of the 4 cases occurring in the Grifton area, 3 had onset of pulmonary disease during the fall and winter of 1954-55, and the fourth patient noted a nodular lesion on the left leg in mid-January 1956. The diagnosis of blastomycosis was established by smear and culture in all of these patients, and all were treated satisfactorily with 2-hydroxystilbamidine.

The occurrence of these cases, as well as the desire to learn more about blastomycin and histoplasmin skin test sensitivity, prompted the second survey.

Method of Study

Because of limitations of time and personnel, as well as the subsidence of the community interest and hysteria engendered by the 1953-54 epidemic, it was decided that a maximum of information could be obtained by skin testing again all individuals who had had positive blastomycin skin tests or positive blastomycosis complement fixation tests in the 1954 survey. In the 1954 survey, 42 individuals given a blastomycin skin test had induration of 5 mm. or more at 48 hours, and 43 individuals, a complement fixation titer of 1:1 or more to *Blastomyces*. Since 2 individuals had both a positive skin test and complement fixation test, the total was 83. Letters were sent to this group requesting that they return for reexamination.

Of the 83 positive reactors in 1954, 43 reported for reexamination. These 43 constituted an excellent and presumably random sample of the 1954 group. Twenty-three of the 42 with positive blastomycin skin tests (54.7 percent) and 22 of the 43 with positive blastomycosis complement fixation tests, including the 2 individuals with both positive skin tests and positive complement fixation tests, composed the 1956 group. The 43 individuals

ranged in age from 3 to 65 years, and 23 of them were under age 20.

One-tenth milliliter of each of the two antigens was injected intradermally. Blastomycin antigen was placed in the right forearm, and histoplasmin in the left forearm, both injections at approximately the same level. New syringes and needles were used for each antigen. In no instance was a syringe or needle re-used during this survey.

The histoplasmin (lot H-42) was diluted 1:100. The blastomycin was a *Blastomyces* vaccine prepared from 6-day yeast phase cultures grown on brain-heart infusion blood agar slants at 37° C. The yeast cells were suspended in saline and heat-killed at 56° C. for 2 hours; the vaccine was diluted 1:1,000 by volume in a Hopkins tube before use. The vaccine dilution, although not strictly an extract, is referred to as blastomycin in this paper. Both of these antigens were supplied by Dr. Norman F. Conant, of Duke University.

At the time the skin tests were read, the individuals surveyed were interrogated about the state of their health. All skin tests were read 48 hours after injection of the antigens by measuring the diameter of areas of erythema and induration with a millimeter ruler. The tests were considered positive when induration was 5 mm. or more and doubtful when erythema was 10 mm. or more.

All 43 participants contributed blood for blastomycosis and histoplasmosis complement fixation tests. These tests were performed at the Communicable Disease Center of the Public Health Service in Chamblee, Ga., through the cooperation of Dr. Kenneth W. Walls.

The *Histoplasma* antigen used for the complement fixation tests was histoplasmin prepared from single strains of mycelial *Histoplasma capsulatum* grown on C. E. Smith's culture medium for the preparation of coccidioidin, incubated at 25° C. for 6 months (3). The cultures were killed with merthiolate, Seitz filtered, and then pooled.

The blastomycosis antigen used for the complement fixation test was prepared from one isolate of *Blastomyces dermatitidis* grown in brain-heart infusion agar at 37° C. for 5 days. The cells from this yeast-phase growth were washed from the agar, killed with merthiolate,

In this 2-year followup of a survey performed in an epidemic area of North American blastomycosis it was found that blastomycin skin sensitivity may be retained for at least 2 years in the absence of histoplasmin sensitivity or evidence of clinical blastomycosis.

Followup of Blastomycin Sensitivity in an Epidemic Area

J. GRAHAM SMITH, JR., M.D., WALTER C. HUMBERT, M.D., and SIDNEY OLANSKY, M.D.

TO GAIN more information about sensitivity to the blastomycin skin test and its relation to reactivity to the complement fixation test, a second survey in the area of Grifton in Pitt County, N. C., was conducted on May 21, 1956. Covering a sample of the persons found positive to the blastomycin skin test or the blastomycosis complement fixation test in the first survey in April 1954, it provides data on conversions and reversions.

The survey in April 1954 was instituted because of an epidemic of North American blastomycosis affecting 11 patients during the winter of 1953-54 in Grifton (1). It included 70-mm. chest X-rays, tuberculin, histoplasmin, and blastomycin skin tests, and blastomycosis

complement fixation tests. No cases of blastomycosis or histoplasmosis were discovered, although one case of active pulmonary tuberculosis was found.

Of the 1,648 persons surveyed in 1954, 2.9 percent were blastomycin sensitive and 6.4 percent were histoplasmin sensitive. There was no correlation of the blastomycosis complement fixation test with blastomycin skin sensitivity. Of the patients with positive blastomycin skin reactions, 4.7 percent had positive blastomycosis complement fixation tests, as opposed to 2.8 percent positive reactors in the total population tested, but 30.2 percent of the individuals with positive histoplasmin skin tests also had positive blastomycosis complement fixation tests, as opposed to only 6.4 percent in the total population.

These findings strongly suggested cross-reactions between the histoplasmin skin test and the blastomycosis complement fixation test. Unfortunately, histoplasmosis complement fixation tests were not done; it was therefore not possible to test the hypothesis that the correlation between the two might be explained by cross-reactions between the histoplasmosis and the blastomycosis complement fixation tests. On the basis of evidence from the 1954 survey it was believed that the sensitivity to both histoplasmin and blastomycin antigens in some

Dr. Smith, formerly at Duke University, is assistant professor in the division of dermatology, University of Miami School of Medicine. Dr. Olansky is associate professor, division of dermatology, Duke University School of Medicine. Dr. Humbert, who was the chief health officer, Pitt County (N. C.) Department of Health, died August 22, 1957.

This paper was presented in part before the American Academy of Dermatology and Syphilology, Chicago, December 10, 1956. It is a follow-up of an earlier study, an account of which appeared in the February 1957 issue of Public Health Reports, pp. 95-100.

at the time of the first survey and was non-reactive to both tests in the second survey, 1 developed histoplasmin reactivity, and 1 lost reactivity to both antigens as mentioned above. Of the 6 individuals with reactivity to both antigens, 2 were still reactive 2 years later.

Twenty of the 22 (91 percent) serums previously reactive to the blastomycosis complement fixation test were nonreactive in 1956. Seven conversions to a positive reaction to the histoplasmin skin test and two conversions to the blastomycosis complement fixation test were observed, but none to the blastomycin skin test. Three strengths of histoplasmin were used in 1954, and 5 of the 7 histoplasmin converters were in the group tested with the weakest histoplasmin (H-42, 1:1,000).

Table 3 shows the correlations of the two skin tests with each other and with the blastomycosis complement fixation test. All the possible combinations of positive and negative reactions to these three tests occurred.

Discussion

There were no cross reactions between the histoplasmosis and blastomycosis complement fixation tests; however, only 4 individuals had reactive blastomycosis complement fixation tests in the second survey. In the absence of clinical blastomycosis, a positive blastomycin skin test was maintained for as long as 2 years. Reversion to negative occurred in a considerable number of individuals, 8 of 23, or 34.8 percent. Reactivity to the blastomycosis complement fixation test was maintained 2 years in 2 individuals, and conversions of the blastomycosis complement fixation from nonreactive to reactive were observed.

The conversions of the histoplasmin skin test from negative to positive were not unexpected in this endemic area (4). The reversion from positive to negative in 1 individual may be explained by cross-reaction to the blastomycin skin test; in the other 2, by loss of sensitivity. These reversions are not unique, such a change having been reported in the past (5, 6). Reversion occurs also with the coccidioidin test in coccidioidomycosis (3) and the tuberculin test in tuberculosis (7).

A positive intradermal reaction to blastomy-

cin with a negative reaction to histoplasmin can occur, and although cross-reactions undoubtedly exist, the possibility that positive reactions to both antigens indicate dual infection, apparent or subclinical, must be considered. This is suggested because over a period of 2 years, of the 6 persons with dual reactivity, 1 lost histoplasmin reactivity retaining blastomycin sensitivity, 2 lost blastomycin reactivity retaining histoplasmin sensitivity, 2 maintained reactivity to both antigens, and 1 lost sensitivity to both. Individuals who have positive intradermal reactions to both antigens and maintain this reactivity over long periods of time may represent examples of subclinical dual infection, whereas those who lose reactivity to one antigen only may represent cross-reactions. Cross-reactivity could also be invoked to explain these changes in sensitivity; however, the occurrence of dual infections in man (8) and dogs (9) would suggest that this may not always be the case. Changes in the size of the reaction to the two antigens with time also may prove to be useful in differentiating the cross-reaction from inapparent or apparent infection.

Correlation of the results of all the tests in each individual shows that all the possible combinations of positive and negative blastomycin skin tests with reactive and nonreactive complement fixation tests may occur in persons who do not have clinical blastomycosis but who live in a blastomycosis epidemic area.

Summary

To examine further the reactivity of healthy individuals in a blastomycosis epidemic area to the blastomycin and histoplasmin skin tests, a second survey was conducted in the area of Grifton in Pitt County, N. C., in May 1956. It included 43 of the 83 persons who had had positive blastomycin skin tests or positive blastomycosis complement fixation tests in a survey in April 1954.

In the 2-year period, 34.8 percent of the previously positive blastomycin skin test reactors had reverted to negative, and 91 percent with previously positive complement fixation to blastomycosis were now negative. No conversions to positive blastomycin skin tests were found in the selected group included in this

centrifuged and washed. A 20 percent suspension of cells was ground with sand (50 percent weight/volume) and centrifuged, to remove the particulate matter. The supernatant fluid was used for the antigen. This was the same type antigen used in the complement fixation tests performed in the earlier study (2). The complement fixations were titrated by the usual "box" titration.

Results

None of the 43 persons surveyed in 1956 gave a history of pulmonary disease, and none of the histoplasmosis complement fixation tests were reactive. The reactivity of the group to the blastomycin and histoplasmin skin tests and to the blastomycosis complement fixation test is shown in table 1. The changes in reaction

Table 1. Reactions to blastomycin and histoplasmin skin tests and to blastomycosis complement fixation test, Grifton, N. C., 1954 and 1956

Reaction	1954	1956
Blastomycin skin test:		
Positive.....	23	15
Negative.....	20	28
Histoplasmin skin test:		
Positive.....	9	15
Negative.....	29	28
Not done.....	5	0
Blastomycosis CF test:		
Positive.....	22	4
Negative.....	17	39
Not done.....	4	0

Both negative.....	11	25

¹ No individuals in this group because of selection of persons for 1956 survey.

NOTE: Only persons tested to both agents included.

from 1954 to 1956 are summarized in table 2.

Many of the persons with positive blastomycin (15 of 23, or 65.2 percent) and histoplasmin (6 of 10, or 60 percent) skin tests remained positive although reversions to negative occurred in both groups. Two of the three individuals whose histoplasmin skin tests reverted to negative had positive reactions to both histoplasmin and blastomycin in 1954. One of these two, a 3-year-old white girl, had an induration of 5 mm. to both antigens in 1954 and no induration to either in 1956. The other, a 9-year-old white boy, had 12-mm. induration with 40-mm. erythema to blastomycin and 15-mm. induration with 20-mm. erythema to histoplasmin in the first survey. Two years later the blastomycin reaction had 5-mm. induration with 11-mm. erythema, but the histoplasmin produced no erythema or induration. The third of the histoplasmin reverts was a 33-year-old woman. She had a negative blastomycin test in both surveys with 12-mm. induration to histoplasmin in 1954 and 4-mm. induration 2 years later.

Of the 8 persons whose blastomycin skin test reverted to negative, 2 maintained reactivity to histoplasmin, 3 showed no reactivity to histoplasmin, 1 was not tested with histoplasmin

The Institute of Agricultural Medicine of the State University of Iowa is unique in that it is devoted exclusively to the public health of rural areas. This interim report gives the first account of its research program.

Institute of Agricultural Medicine in Iowa

RICHARD A. TJALMA, D.V.M.

IN CONTRAST to urban dwellers, rural families have enjoyed relatively little of the protection afforded by public health agencies. For this reason, research at the Institute of Agricultural Medicine at the University of Iowa has undertaken exploratory studies of rural health, with identification of major needs as its first concern. With sympathetic collaboration by investigators in other centers, a general evaluation and demonstration of rural health programs will ensue.

Public health functions, historically, have been designed and organized to serve urban populations. Particularly is this true of the epidemiology of infectious disease, the foundation of public health work. The massing of large populations created an excellent breeding ground for epidemic and endemic infections. The wealth and governmental experience of the cities at the same time provided facilities for public health activity; otherwise, the cities would have perished.

Traditional public health methodology is not always applicable to rural conditions. Techniques of control and investigation, designed for urban settings, frequently are not well suited to the sparsely settled communities. The nature of local government structure in

Dr. Tjalma is assistant professor of the department of hygiene and preventive medicine of the College of Medicine, State University of Iowa.

some rural areas precludes the establishment of typical administrative public health programs. Disease and accident reporting, a prerequisite to efficient public health programming, is inadequate especially in areas that are not organized on a communitywide basis. Considerable study is needed to determine what the real health needs of rural populations are, how health services for rural segments of the population are being met, and wherein they can be improved.

Rural Health Hazards

The saying, "The farm is the safest and healthiest place in the world to live," is frequently heard in rural areas. Although it may be the "healthiest," available statistics show it to be something other than the "safest" place in which to live. The number of farmers killed on the job in 1955 exceeded that of any other single occupational group. Of a total of 14,200 occupational deaths, 3,700, or 26 percent, occurred among farmers, estimated at only 7 percent of the working population. On the basis of rates of fatal on-the-job accidents, farming is the third most dangerous occupation, only mining and construction outranking it (1a). The total number of farm injuries in 1956 was 1,050,000 (1b). Tractor accidents alone account for approximately 700 deaths among agricultural workers each year.

The variety and amount of chemicals in com-

survey, but two individuals previously negative to the blastomycosis complement fixation test were found to be positive.

Both skin sensitivity to blastomycin and blastomycosis complement-fixing antibodies tended to decrease in the 2-year period, but the complement-fixing antibodies disappeared in a higher percentage of the individuals tested.

Seven persons became reactive to the histoplasmin skin test and three lost their reactivity. The loss of reactivity in one instance might possibly represent cross-reactivity to the blastomycin skin test. None of the group surveyed had a positive histoplasmosis complement fixation test.

Training in the Care of Prematures

The tenth year of the institutes for physicians and nurses in the care of premature infants will begin in the fall of 1958. The institutes are sponsored by the New York State Department of Health and the U. S. Children's Bureau.

The training is planned to meet the needs of physicians and nurses in charge of hospital premature nurseries and premature centers, and medical and nursing directors and consultants in State and local programs.

Attendance at each institute is limited to six physician-nurse terms. For physicians, the program lasts 2 weeks, and for nurses, 4 weeks. There is no tuition fee, and stipends are provided to help cover expenses during attendance. The institutes are scheduled to begin September 22, 1958; November 3, 1958; January 12, 1959; February 23, 1959; and April 20, 1959.

For additional information, write to Box 143, Institute in the Care of Premature Infants, New York Hospital, 525 East 68th Street, New York 21, N. Y.

Institute of Agricultural Medicine in Iowa

RICHARD A. TJALMA, D.V.M.

IN CONTRAST to urban dwellers, rural families have enjoyed relatively little of the protection afforded by public health agencies. For this reason, research at the Institute of Agricultural Medicine at the University of Iowa has undertaken exploratory studies of rural health, with identification of major needs as its first concern. With sympathetic collaboration by investigators in other centers, a general evaluation and demonstration of rural health programs will ensue.

Public health functions, historically, have been designed and organized to serve urban populations. Particularly is this true of the epidemiology of infectious disease, the foundation of public health work. The massing of large populations created an excellent breeding ground for epidemic and endemic infections. The wealth and governmental experience of the cities at the same time provided facilities for public health activity; otherwise, the cities would have perished.

Traditional public health methodology is not always applicable to rural conditions. Techniques of control and investigation, designed for urban settings, frequently are not well suited to the sparsely settled communities. The nature of local government structure in

some rural areas precludes the establishment of typical administrative public health programs. Disease and accident reporting, a prerequisite to efficient public health programming, is inadequate especially in areas that are not organized on a communitywide basis. Considerable study is needed to determine what the real health needs of rural populations are, how health services for rural segments of the population are being met, and wherein they can be improved.

Rural Health Hazards

The saying, "The farm is the safest and healthiest place in the world to live," is frequently heard in rural areas. Although it may be the "healthiest," available statistics show it to be something other than the "safest" place in which to live. The number of farmers killed on the job in 1955 exceeded that of any other single occupational group. Of a total of 14,200 occupational deaths, 3,700, or 26 percent, occurred among farmers, estimated at only 7 percent of the working population. On the basis of rates of fatal on-the-job accidents, farming is the third most dangerous occupation, only mining and construction outranking it (1a). The total number of farm injuries in 1956 was 1,050,000 (1b). Tractor accidents alone account for approximately 700 deaths among agricultural workers each year.

The variety and amount of chemicals in com-

Dr. Tjalma is assistant professor of the department of hygiene and preventive medicine of the College of Medicine, State University of Iowa.

mon use on the farm suggest another health hazard. Expanding agricultural application of insecticides, fumigants, herbicides, rodenticides, fungicides, and even fertilizers has resulted in no less than one-quarter million brand-name chemical products now being used. An estimated national total of 3,300 accidental deaths are caused each year by the misuse of chemicals (2). Commercial label warnings, including instructions concerning precautionary measures, are often impractical under field conditions.

By virtue of their occupation, their environment, or both, farmers and other rural dwellers are frequently exposed to animal diseases. Iowa, with a total human population of approximately 2.5 million, has a domestic animal population which includes 6.5 million cattle, 1.3 million sheep, 12 million swine, and 30 million fowl (3). In addition, it is estimated there are more than 1 million dogs and cats.

Establishment of the Institute

Iowa, with a substantial rural population, has a vital interest in the health of agricultural workers. The opportunity to explore this area on an organized basis was made available by a 3-year grant from the W. K. Kellogg Foundation in September 1955. The Institute of Agricultural Medicine, the first in the United States, was established as a part of the department of hygiene and preventive medicine of the College of Medicine, State University of Iowa. After expiration of the original grant, the institute will continue to function as an integral part of the College of Medicine. Present personnel consist of a medical director, an industrial hygienist, a social anthropologist, a toxicologist, a statistician, and a public health veterinarian. Future plans call for the addition of a health educator and a safety engineer.

As originally conceived, the function of the institute is the demonstration and evaluation of public health problems of a rural nature. Activities of a control or regulatory nature are not considered a part of the institute program. A close working relationship has been established with the following groups and agencies: Iowa State Medical Society; Iowa State Department of Health; the Iowa Farm Bureau Federation; the School of Veterinary Medi-

cine, the School of Agriculture, the School of Engineering, and the Extension Service of Iowa State College.

Survey for Baseline Data

Our initial problem was lack of basic rural public health data. Limited available information served only to suggest probable or potential rural health problems. Epidemiological information on infectious diseases, accidents, and other suspect problems was nonexistent. In an effort to establish baseline information, an extensive rural health survey has been designed. It is expected this study will result in the recognition of specific problem areas. Future activities can then be designed to investigate these areas in detail.

Classical toxicology studies of hazards in the agricultural use of chemical products based on short-term animal experimentation are time consuming and expensive and their results questionable when applied to humans. The institute has established facilities to investigate the possibility of utilizing tissue culture techniques as a method of toxicological evaluation.

Accident prevention studies may be organized on an anthropological basis. Why do different ethnic groups, living in geographic proximity, engaged in the same tasks, and using essentially the same equipment, have significantly different accident rates? Why are certain groups of individuals willing and eager to use safety devices, while other groups refuse to consider the use of such items? To what extent are advances in agricultural mechanization responsible for accidents? These and similar questions may be answered by socioanthropological investigation.

Recent studies in this area indicate certain groups consider safety devices "sissyfied" and therefore unacceptable. In many areas it is considered quite reasonable not only to dispense with personal safety gear but also to remove these safeguards built into farm machinery. This is particularly true for cornpickers and power takeoff systems. The institute in collaboration with a local Iowa company has developed a cornpicker safety tool. A controlled field trial of this new tool, including a group acceptance study, is now in progress.

A study designed to investigate the differences between various groups in accepting routine immunization procedures has been completed. Families in the lower socioeconomic brackets were found to neglect routine immunizations when left to their own devices. Specific suggestions by the family doctor had little or no influence. However, such families were quick to participate in any sort of community-sponsored immunization program.

Zoonotic Patterns

Animal diseases are of importance to the health of rural people. Of the 115 diseases in this category, approximately 40 are known to occur in Iowa. Although classic epidemic disease patterns are infrequently observed in rural populations, epizootics of animal diseases may be expected to occur in rural areas. Recognition of an epizootic pattern is frequently the most efficient method of identifying a potential or existing human health hazard.

Leptospirosis constitutes a rural health hazard of unknown proportions. Repeated surveys in various parts of the United States have shown that 3 to 12 percent of the cattle population is serologically positive for leptospirosis (4-8). The incidence of leptospirosis in swine is thought to be considerably higher (5, 9). Relatively little investigational work has been done on human leptospirosis in Iowa. Serologic diagnostic facilities are unavailable at either the medical college or the laboratories of the Iowa State Department of Health.

Only recently have such facilities been established at the School of Veterinary Medicine. To gather baseline data on the incidence of human leptospirosis the institute now is testing all serum samples submitted to the laboratories of the State health department. The vast majority of these samples are submitted by practicing physicians for brucellosis testing. On the basis of some 3,000 such tests, approximately 2 percent are *Leptospira* positive. A similar survey of 1,000 premarital blood samples has resulted in the detection of only one positive specimen. Future activity in this area will be the routine investigation of all serums positive to *Leptospira*.

Q fever has been demonstrated as existing

in enzootic form in Iowa dairy cattle (10). Although less than 1 percent of the cattle appear to be infected, it is estimated that 3.5 percent of the dairy herds contain one or more infected animals. *Cowdella burnetii* has been isolated from the milk of serologically positive cattle. Preliminary human serologic studies show 8.5 percent of 200 Iowa veterinary practitioners to be Q-fever positive.

In cooperation with the State and Federal departments of agriculture, and the Iowa State Department of Health, an attempt is being made to investigate the possible relationship between tuberculosis in farmers and the occurrence of tuberculin-positive cattle. Particular attention is given the matter of tuberculin-positive cattle which appear to be free of lesions at slaughter inspection. This project is supported by a grant from the Iowa Tuberculosis and Health Association.

Iowa's poultry industry is rapidly expanding. Several cases of suspect human psittacosis due to domestic fowl contact have been investigated. The possibility that psittacosis is occurring in domestic fowl in Iowa is currently under investigation. This study comprises the routine screening of fowl serums for evidence of infection. A field trial of the antibiotic and millet seed preparation, as perfected by Dr. K. F. Meyer for the control of psittacosis infection in cage birds, has been completed. The product proved completely effective.

Rabies constitutes another serious problem in Iowa. Efforts have been made to isolate rabies virus from both normal and abnormal Iowa bats. All such efforts have proved unsuccessful to date. The fact that most barns house a bat colony serves to stimulate interest in this problem.

A project protocol has been written and an enabling grant received for the epidemiological investigation of toxoplasmosis. The results of preliminary studies indicate a high correlation between human toxoplasmin sensitivity and a history of routine animal contact. Of particular interest is the role of *Toxoplasma* in cases of degenerative retinitis in farmers.

Future research plans of the institute include a study of rural mental health. Iowa's suicide rate is 30 percent above the national average. Consideration is being given the matter of de-

laid or chronic sequelae of infectious diseases such as brucellosis. An attempt will be made to explore the effects and methods of rural health education.

Perrott Retires

George St. J. Perrott, chief of the Division of Public Health Methods of the Public Health Service since 1939, retired June 30, 1958.

Director of the National Health Survey during 1935-36, he also directed the development of the National Health Survey established in 1957. Mr. Perrott has been associated with the direction of *Public Health Reports* since 1943 and was a major influence in the decision to convert the weekly edition to an expanded monthly journal in its present form. He has been managing director of *Public Health Reports* since 1952.

Mr. Perrott first joined the Public Health Service in 1933 as principal statistician. Previously, he served with the Bureau of Mines, where, from 1927-31, he directed the activities at the Pittsburgh Experiment Station, a research center for studies on health and safety in industry.

From 1917 to 1927, he was a chemist with the Chemical Warfare Service in Pittsburgh;

during a Washington assignment with the Warfare Service in 1918-19, he carried the rank of first lieutenant.

Recognized as a national authority in health statistics, Mr. Perrott received his education at the University of North Dakota and Princeton University. He is a member of the American Statistical Association.

Dr. William H. Stewart, special assistant to the Surgeon General for program operations since 1957, succeeds Mr. Perrott as chief of the Division of Public Health Methods.

Dr. Stewart was commissioned in the Public Health Service in 1951, serving as chief of the Epidemiological Unit of the Communicable Disease Center at Thomasville, Ga., during 1952 and 1953. After assignments with the Heart Disease Control Program in the National Heart Institute in 1953 and 1954, he was named assistant chief and then chief of that program in the Bureau of State Services. In 1956 Dr. Stewart became assistant director of the National Heart Institute.

With prevention of mental illness a goal and psychiatric time limited, this health department assigns supportive roles to nurses and consultative roles to psychiatrists. Cooperation with schools, official and voluntary agencies, and State mental hospitals aids in progress toward the goal.

A Health Department's Activities in Mental Health

H. L. BLUM, M.D., M.P.H., and W. A. KETTERER, M.D., M.P.H.

NEITHER a psychiatrist nor a psychiatric clinic was available in Contra Costa County, Calif., 10 years ago to handle the problems of emotional illness encountered by the Contra Costa County Health Department. During these years, we have sought to increase the staff's understanding of emotional illness, to promote better interpersonal relationships among members of the health department and other related groups, and to find the optimum use of psychiatrists and nurses in consultative and supportive roles. In addition, we have engaged in many community activities, such as family life education, to promote better mental health.

Contra Costa County, located east of San Francisco Bay, grew 300 percent between 1940 and 1950 to a total population of 299,000. By 1957, with growth continuing at a much slower rate, the population had reached 375,000. The health department was modest in size until 1950 when it began to expand, with services shaped to the community's needs. A decentralized working staff of sanitarians and nurses serve and represent the health department in specific geographic areas. In the county pat-

tern schools provide their own nurses, while the health department provides medical, dental, nursing, health education, sanitation, and other consultative services to any school desiring them.

Although the health department provides extensive clinic services, increasing industrialization and the spread of medical care insurance have somewhat decreased the problems of providing medical care. And, with health department emphasis on preventive rather than therapeutic medicine and encouragement of "whole care" in public and private practice, the actual ratio of population to clinic use has declined significantly in the past few years.

Initial Planning in Mental Health

In 1948, it became apparent that some of our persistently vexing problems in public health centered upon emotional illness. Three other county agencies felt similarly about many of their problems, and an informal meeting was arranged for representatives of the Contra Costa County welfare, school, probation, and health departments to consider creating a psychiatric or child guidance clinic. With our very limited means, it soon became clear that a clinic seeing so few patients would rapidly become saturated and its use to us would be minimal.

Dr. Blum is health officer and Dr. Ketterer is assistant health officer of the Contra Costa County Health Department, Martinez, Calif.

Thus, a concept developed that mental health activities in the county would have to be more than a series of therapeutic situations between the psychiatrist and individual patients. We felt that a consultant psychiatrist could assist certain groups of professionally trained workers with mental health problems. The training of professional workers would result in the availability of many mental health services throughout the community on a scale quite impossible if the same limited psychiatric time were available only in a clinic situation. Therefore, arrangements were made for each agency to receive psychiatric consultation for one-half day a month. It was agreed to keep this experimental approach open to modification.

Development of the original scheme resulted in the inclusion of more county agencies in the psychiatric consultation program and the formation of the Mental Health Coordinating Committee of county agencies. Today, this committee comprises the department heads of nine different county agencies with whom a psychiatrist meets monthly. This body of administrators acts as a steering committee for the entire program, sets policy, plans, coordinates, evaluates, and determines allotment of time and financing. Broad framework is set up, but each agency has freedom in how it uses its share of psychiatric time. The total program involving all county agencies concerned in 1948 originally commanded 3 hours weekly from one psychiatrist. In 1958, there are 68 hours available from 9 psychiatrists.

In the beginning, after a few sessions of the health department with the psychiatrist we saw that we needed to learn how to deal with mental health problems and how they affected us personally. Staff members' personal problems relating to their job success called for consideration and understanding. For certain of our personnel, difficulties in work situations and interpersonal office relationships had to be remedied for more effective functioning within the staff, with other agencies, and with clients. It also became apparent that the staff members did not clearly understand their responsibilities or the goals they were trying to achieve.

Thus, through 1954, the psychiatrist served primarily as a consultant on administrative problems at various levels. The purpose here

was to ease interpersonal relations and to improve our understanding of emotional problems.

Nurses Assigned Patients

During 1954, the health department's opinion crystallized into the belief that the real need for psychiatric consultation lay in providing the nursing staff with the specific management techniques and didactic materials that would enable them to help their patients.

The health officer decided, without much group support and with some misgivings of the staff and the psychiatrists, that the majority of psychiatric time should be used to supervise, directly or indirectly, nurses who would be assigned emotionally disturbed patients. It was reasoned that the nurses would develop a better understanding of psychological procedures if they were confronted with a specific patient who had an acknowledged need for mental health guidance. Responsibility for an emotionally disturbed patient would plunge the nurse into actual work in this field. It was also reasoned that individual casework would provide good material for lectures and group discussions of the problems encountered.

Opponents reasoned that the plan would precipitate personnel into an assignment they were not prepared for. The health officer interpreted this argument as being almost a restatement of his own feelings that the years of discussions were simply postponing and probably encouraging avoidance of dealing with emotional problems.

The issue was resolved by the inception of our present system of public health nurse followup. In order to make such an extensive approach feasible, the department created the position of mental health nursing consultant and employed a public health nurse with special training.

Cases are chosen from among clients who come to the county hospital psychiatric unit, or from those found by the public health nurse among her district clients, and whose diagnosis indicates no frank psychosis or outstanding need for hospitalization. The patients chosen are often unable or unwilling to come to a psychiatrist, but can be visited in their homes or they can visit the public health nurse in her

district office. Assignments are made according to the client's place of residence; our public health nurses are generalized and have geographic districts. Each patient determined to be psychiatrically suitable is invited to a discharge conference attended by the field public health nurse and her supervisor, our mental health consultant, the psychiatrist, and the chief nurse of the hospital's psychiatric unit. After a professional discussion, the psychiatrist asks the patient to join the conference, introduces him, and holds a short interview for the benefit of the nurse. The patient then retires and the group completes its discussion.

This conference establishes a working diagnosis, explains the personality of the patient, indicates his past and expected behavior, and presents social, home, cultural, and economic factors. The nurse receives suggestions and recommendations regarding her relationship to the patient and the patient's environment, and has an opportunity to express her own feelings about the particular patient, whether they be inadequacy, fears, or conflicts. The psychiatrist can help the nurse understand her feelings. The conference enables the supervisor to understand the case and the feelings of the nurse, and to see how they are handled by the psychiatrist. It provides an opportunity for the supervisor to ask questions pertaining to her own role, the field nurse's plan for assistance, and related matters. The patient is given a chance to meet the nurse through the psychiatrist and to make an appointment for nursing visits.

If the public health nurse has additional problems during home or office followup, she returns to her supervisor for consultation. If the supervisor feels unable to assist, both turn to the mental health consultant, who spends approximately one-half of her time assisting the field staff and their supervisors with such cases. If necessary, the mental health consultant arranges for further interviews with the psychiatrist, who occasionally reevaluates the case. The mental health consultant also has 1½ hours a month for individual consultation with the psychiatrist.

The psychiatrist is also available every other month for a 1-hour meeting with each group of nurses and their supervisors in the six dis-

tricts and the mental health consultant. In addition, 2 hours are available monthly for the entire supervisory group and the nurse consultant. This time may be used to discuss cases presented from the field, whether previously seen by a psychiatrist or not, or to have the psychiatrist fulfill specific requests for lectures and discussion materials.

In 2 years, 1955 and 1956, approximately 250 cases were the subject of psychiatric consultation. Service ranged from a single visit to a series of 60 regular nursing home visits over the 2-year period. Although we are impressed with the results of extending the psychiatrist's services beyond direct contact with patients, we realize that only a small part of the total mental health problem is being touched with our field services.

As a result of this program, the public health nurses are generally satisfied that they are beginning to understand dynamic psychiatry and are putting it to use in their own actions and relationships to patients. Generally, it seems that acknowledging responsibility for services to emotionally disturbed persons is a marvelous learning experience. Prior to actual assignment of cases, didactic information and discussion had not really stimulated the nurses to positive action in dealing with cases of emotional disturbance that are inevitably part of their caseload. Some nurses, however, are not yet able to work with such cases or certain kinds of cases.

The district supervisors without case experience and the higher echelon of nursing supervision now desire the same opportunity. Five out of eight have requested and have been assigned disturbed persons. For theoretical and administrative reasons the supervisory groups should not lag behind the field personnel in understanding, and they also confer with the mental health consultant. It may well be that the top administrative ranks, including health officers, will wish to be assigned disturbed persons, serving what might be called psychiatric internships.

Responsibility for Program

At the same time that nurses were given the direct responsibility for assisting selected emotionally disturbed patients, the assistant health

officer in charge of venereal disease control was given responsibility for the mental health program. This physician is not a psychiatrist, but he has participated in the evolving programs during most of the 10 years and recently worked briefly on the psychiatric staff of a State hospital. In addition, he has been assigned to represent the department's non-nursing activities in community mental health. Under his direction a manual has been developed outlining the plans under way in each division of the health department and the role that each employee plays in the mental health program. We believe that official assignation adds prestige to the activities and provides a tangible means of direction, continuity, and evaluation.

Community Activities

In addition to the public health nursing activity in the emotionally disturbed cases, we are concurrently engaged in several community activities to promote mental health. We have augmented the maternal and child health programs, encouraged family life education courses, worked with voluntary agencies, and have developed a cooperative arrangement with the California State Department of Mental Hygiene, the agency responsible for the rehabilitation of county residents discharged from the State mental hospital.

Family Life Education

The foundation for mental health, much like the foundation for physical health, is laid early in childhood. Preventing mental ill health and creating a sound family life through family life education in the school are activities that take into account future generations. Many maintain that this is the responsibility of parents, but too few parents are adequately informed. Many are hesitant; others are unhappily married or do not have the time or the desire to provide this training. On the other hand, the careful integration of courses in family living, from kindergarten through college, can help in the creation of responsible parents whose children will be healthier mentally and more stable emotionally.

In 1953, a survey of all county schools revealed courses in family living were largely

absent, particularly in grade schools. At that time, the health department has attempted to stimulate school administrators, parent groups, church groups, and others to family life education courses in schools. This is done by such means as teaching and assisting with films and reference materials. To expedite school and community acceptance of courses on human development, venereal disease, and similar topics, a professional person is sometimes needed. Thus, the assistant health officer in charge of mental health or person chosen by him may be the initial lecturer. With regard to the arranging of curriculum and teaching as a job for trained school personnel, an attempt is made to tell the school personnel how to give the course, nor do we teach, except as explained above. However, the assistant health officer offers guidance in areas to be covered. Whenever it appears that a particular school district has some interest in the topic, whether in elementary or secondary schools, the health department adds its weight to the movement.

Maternal and Child Health

Special mental health problems seem to cluster about certain groups in the population, many well known to the health department. Pregnant women constitute one of the major groups. In the maternal and child health program, both the clinic services and home calls to pregnancy cases are geared to a consideration of the special problems, particularly those of unwed mothers.

Another area of tremendous scope is our program for the newborn, the infant, and the preschooler. Here, the nurse through her home visits and the clinicians in well-child conferences have opportunities to work with special risk groups in allaying fears, offering advice, understanding parental anxieties, and paving the way for a more normal childhood. Our specialist director of maternal and child health supervises the clinicians. We have at times paid for and provided courses on growth, development, and emotional needs for these physicians. Rather than have a full-time specialist staff, we prefer employing part-time clinicians who are general practitioners in the community. Our objective has been to spread more of the mental health "know-how" among

the doctors through special training. We hope they will provide more preventive care to families in their own practices through their increased awareness and interest in foresighted guidance.

Other major programs are currently geared to consideration of the mental health aspects likely to be associated with the primary conditions for which the program was created.

Our crippled children's services offer opportunities for dealing not only with handicapped children but also with parents who experience rejection, guilt, inadequacy, unwillingness to go ahead, and related difficulties. Our tuberculosis and venereal disease programs particularly offer many challenges. Here again fears, guilt feelings, domestic problems, and potential socioeconomic losses are expected to engender or worsen emotional disturbances. In these, our nursing services in particular (to a lesser extent our clinic services) can be of great help. In many instances we have been of fundamental assistance to our clients in their emotional problems.

Assisting Voluntary Agencies

Nationwide, a great need is recognized for public education and support in mental health. Voluntary citizens groups and associations are major means of realizing these goals. Recognizing this, our health department stimulates and assists many organizations dealing broadly with mental health or various facets of it. Responsibility for this endeavor rests largely with the assistant health officer in charge of the mental health program. It has also been shared by the health officer and by the assistant health officers (particularly those in charge of maternal and child health, crippled children's services, and school health), health educators, and the public health nursing staff.

Characteristically, the organizations dealing with mental health have been small, with limited budgets, personnel, and activities. The health department participates in organizing, developing programs, and forming policy. Clerical assistance, health education materials, and press releases are provided during crises, especially in the early development of a voluntary agency. Usually the department does not provide "legwork" for voluntary agencies, since

we feel they can promote their cause better when their services are carried out by participating volunteers.

Members of the health department's staff are often members of the board of directors or committees of an agency and frequently are on the speaker's bureau. However, staff members do not accept executive positions such as president or chairman of a voluntary agency or its committees. We believe community voluntary workers should formulate a truly community program and avoid the possibility of being dominated by official agencies or of becoming an "arm" of the health department.

Since we must spread ourselves thin by participating in many voluntary agencies, we are constantly aware of the importance of assessing the value and goals of each agency in relation to the mental health and the total health picture. We attempt to devote our limited time to programs in which the most can be accomplished, preferably with the smallest investment of time and money. An example is our extensive participation in the Contra Costa-Alameda Epilepsy League. In our area, epilepsy is still neglected medically and shunned socially, and epileptics are rejected by schools and employers. The condition is comparatively easy and inexpensive to control, but does not receive a fraction of the attention justified compared with poliomyelitis or cerebral palsy, each of which it outnumbers sixfold.

Cooperating With the State

In the sphere of rehabilitation, we now work with the psychiatric social worker from the California State Department of Mental Hygiene, who has the legal responsibility for followup and rehabilitation of county residents discharged from the State mental hospital system. Our health department's role is primarily one of nurse cooperation. The nurse has a supportive relationship with some families and assists with the material needs of the discharged patient and his family.

The distances of the State hospitals from Contra Costa County have precluded a more direct relationship to date. However, our mental health consultant has established mutually helpful relationships with the nearby Berkeley outpatient clinic of the State Department of

Mental Hygiene. Previously, the health department and other agencies of the community referred cases there but immediately lost contact. We neither profited from the therapeutic experiences nor did we contribute in any way. Now we are able to furnish a more pertinent summary of findings and background on the patient and his family when we refer patients. In turn, the outpatient clinic provides the health department with pertinent information on these patients. The clinic, which has no home visiting services, has the benefit of our psychiatrically oriented staff.

Discussion

Certain basic tenets were assumed in determining the framework of the original mental health program.

1. Emotionally disturbed persons brought to an agency's attention are often in a phase of exacerbation and have passed through a prior phase in which the illness was less severe or fixed, but nevertheless under way (1).

2. It should be easier to reach such persons therapeutically at a time when their illness is less fixed, when they and others in their environment are less pessimistic in attitude. Presumably, at this time they can be assisted with a lesser expenditure of limited psychiatric resources (2).

3. It should be possible to provide many persons in the early stages of their disturbances with a supportive relationship through their contact with workers who are not psychiatrists but are employed by agencies whose work unveils emotional implications. If these workers are well indoctrinated in psychiatric principles and can work with psychiatric guidance, they should be able to accomplish a great deal. A. D. Schwartz, in an unpublished paper, calls them "caretaker persons" and points out that they may exist in or out of agencies or organizations. Those in agencies should be easier to mobilize.

4. It should be possible to utilize the services of a high proportion of professional people such as school guidance workers, probation case-workers, social welfare workers, medical social workers, public health nurses, teachers, and others. This group numbers about 1 percent of the general population and 2 percent of the

adult population and has a large number of public contacts as well as some psychological orientation.

5. It might be possible to transmit continuously a significant amount of psychiatric understanding and working know-how from the psychiatrist to these field workers. This would probably be most successful if the information were mediated by another small but strategically placed group of workers who are equipped with significant psychiatric skills. These are the psychologists, psychiatric public health nurses, and psychiatric social workers.

Restated, the field worker in a supportive relationship with many disturbed persons would work closely with skilled intermediaries who in turn would deal directly with the psychiatrist. In this way the limited services of a psychiatrist could be extended through many professional workers or "caretakers" to a great number of their contacts. We have called this the "trickle down" approach.

The team headed by a psychiatrist has to develop an appreciation of community problems, socioeconomic groups, cultural patterns, organizations, and governmental agencies. Through an extensive training program (which we think should include closely supervised work with a limited number of clients), the psychiatrist helps train several echelons of mental health workers. The more psychiatrically skilled of these (in the health department, this would be the nurse mental health consultant) would primarily assist him by acting as consultants to the field workers. The field workers promote mental health concepts through the use of specific preventive techniques geared to the various groups of their "at risk clients." The field workers learn early to recognize emotional problems near their inception. The workers handle cases when they feel capable and refer more difficult ones to higher echelons. When a nurse assists in rehabilitating a posthospital or clinic patient referred to her, she receives instructions from the psychiatrist in order to achieve optimal family and community adjustment and acceptance for the patient.

Field personnel have many contacts with personal health problems and defects revealed by screening procedures or law enforcement activities. If clients are approached suitably, the

agency's goals are more likely to be achieved, and anxiety-producing situations are minimized. The worker's growth and increased skills in interpersonal relations enable him to avoid recalcitrancy, and possibly enable him to prevent violations of the law that result in legal prosecution with its antisocial and mental health consequences for the individual and his family.

Appreciation by the oriented worker of the need to define choices clearly for the potential law violator or victim of disease can be the stimulus for healthy decisions and the patient's moral growth. Our health department has seen successful contacts alter the attitude of fairly well-confirmed antisocial persons and apparently help reincorporate them into the community. By contrast, we have maneuvered persons into becoming hostile recalcitrants, even though they have really never before come afoul of basic community requirements.

Among the benefits that were foreseen in well-planned, psychiatric indoctrination was the clarification of administrative relationships. The very necessary administrative hierarchy is automatically an imposition in a democracy and resentments, always difficult to overcome, block communications and lead to misunderstandings (3). Any improvements in the field worker's understanding and acceptance of the proper exercise of authority and worker-supervisor relationships should result in less ambivalent feelings at the field level about law enforcement and the functions to be accomplished with clients. In strengthening the worker's ability to win the client's cooperation, the accomplishment is much more gratifying. Well-established communication lines that permit the worker to transmit his thoughts about his client help the agency do its job.

We also find more understanding between agencies. Frequently dealing with the same families, agencies often follow upon one another's footsteps and interfere with one another's attempts to assist a client. An appreciation of another agency worker's policies, legal limitations, and problems is therefore essential. Each affects the client whose welfare and peace of mind, if properly promoted, can lead to the amelioration of his status or his dismissal from the category of "client." By mutual agreement, basic work with a family

can be assigned to the one agency worker most concerned. Success in this area involves extensive free-flowing communications. It is our feeling that our mental health program has paid for itself by keeping administration and worker lines of communication open.

For the price of inservice training, it has been possible to expedite the administrative duties and functions of the health department. Fixing responsibilities for our mental health program in addition to the inservice training has succeeded in interesting everyone in the emotional aspects of their services.

We also feel that we can extend the community psychiatric resources through public health nursing services. This has not been inexpensive, but examination of a few apparently successful case histories indicates that for a very few hours and dollars large individual community savings are achieved.

Cost is not the only factor. A clinic cannot serve some of the clients that we do because some persons are not adequately motivated to seek help from a psychiatrist or clinic, nor do they require hospitalization. A nurse's relationship with a patient can be more felicitous; for a patient initially is likely to be less awed by a nurse's presence than a doctor's. A nurse may also be accepted by persons who will not deal with anyone having a psychiatric label. At least in a few cases, it was only after a good many home visits by a nurse that the patient's attitude changed enough to induce him to avail himself of psychiatric services.

Summary and Conclusions

The Contra Costa County Health Department's mental health program, although incomplete and inadequate from the standpoint of the whole problem, has explored and incorporated several projects in prevention of mental illness.

Promotion of mental health is carried out in all our general programs, including those in sanitation. More specifically, our maternal and child health program is geared to this approach in prenatal, parental, and child guidance. Encouragement of family life education in schools is a similar activity.

Limitation of apparent disturbances are also of major concern in these programs and par-

ticularly in our crippled children's, tuberculosis, venereal disease, and chronic disease services.

Direct assistance to the emotionally ill and to those being rehabilitated during or following therapy is a specific activity of our mental health program.

We feel that the health department's limited use of a consulting psychiatrist, extensive use of a nurse mental health consultant, and reliance on field nursing for patient supervision is one successful approach in furthering mental health. Proper indoctrination and training enables our field staff to help with many lesser conditions and to recognize and refer the more severe to the more psychiatrically skilled. Utilization of professional "caretaker" personnel seems to be an economical and feasible way to get mental health services to a great number of persons, particularly when psychiatric services are minimal or absent.

Most of the nursing field staff did not work readily with families or individuals with mental health difficulties until given specific case assignments. Classes and case presentations became of more value once the nurses had specific

cases and needs. Heavy turnover of nursing personnel makes it unlikely that usual inservice training or course work can be expected to prepare the staff as successfully as actual case responsibility with good supervision and consultation under overall guidance of psychiatrists.

There was need to formalize our mental health activities into a specific program and to assign an assistant health officer as program director. The program's importance was thereby recognized and responsibility for direction, supervision, and evaluation was established.

Administrative improvements, intra-agency and interagency relationships have been a major consideration with particularly significant gains in the latter.

Course in Laboratory Methods in TB Diagnosis

A course in laboratory methods in the diagnosis of tuberculosis is offered by the Microbiology Laboratories of the Communicable Disease Center, Public Health Service, Chamblee, Ga., in cooperation with the Service's Division of Special Health Services. The course, scheduled for October 20-31, 1958, and for January 26-February 6, 1959, is open to all grades of employed laboratory personnel who have the approval of their State health officers.

The training includes preparation of culture media, microscopy, cultural procedures, diagnostic use of animals, and testing of drug sensitivity. Students attending will be offered a "student extension service" for a period of 1 year following termination of the course.

No tuition or laboratory fees are charged. Reservations for this course should be made well in advance, since the size of each class is limited to 12.

Application forms may be obtained from the Laboratory Branch, Communicable Disease Center, Public Health Service, P. O. Box 185, Chamblee, Ga.

A study of referrals to public health agencies among 1,263 households showed that the majority of the time and patient-nurse contacts are devoted to the first patient, and usually less than two additional patients come from the same household.

Public Health Nursing Service Provided in Households

MARION FERGUSON, R.N., Ph.D., and MARY ELLEN PATNO, Ph.D.

THE AMOUNT of public health nursing service needed by patients under the care of local health departments has been the subject of much speculation, the topic of many conferences, formal and informal, and the research objective of various studies. This report deals with one aspect of the problem—the amount of public health nursing service that ensues in a household as a result of the referral of the first patient.

Source of Data

The basic data for this report were collected by 2 nurses in each of 8 health agencies in 5 States over a period of 2 years. The agencies were the Frederick County Health Department, Maryland; Detroit Department of Health and Washtenaw County Health Department, Michigan; Rochester Health Bureau and Tompkins County Health Department, New York; Forsyth County Health Department, North Carolina; and the Fredericksburg Health District and the Community Nursing Service of Richmond, Virginia.

Dr. Ferguson is chief of Public Health Nursing Studies, Division of General Health Services, Public Health Service. Dr. Patno is assistant professor of biostatistics, Graduate School of Public Health, University of Pittsburgh.

These agencies met the criteria of the American Public Health Association for health department programs, and the nurses fulfilled the criteria of the American Nurses' Association and the National League for Nursing for public health nursing programs, staffing patterns, and basic public health nursing preparation of the staff. These agencies and nurses also were ones that, in the professional judgment of the responsible State health officials, were maintaining standards of good public health practice (1).

Households in this study comprised all persons living in one dwelling unit, such as an apartment or a private dwelling, but did not include family members living elsewhere. Beginning with referrals on February 1, 1954, each nurse admitted for study the households of the first 10 patients referred in each category of service where the agency assumed responsibility. Thereafter, she recorded, among many other items, the amount of service provided to all members of the household from the time of referral to discharge or for a period of 1 year, whichever came first.

The participating agencies provided services in all areas usually considered health department responsibility, but the number and type of categories used in reporting service varied considerably from agency to agency. Because

of this variation, all initial patients and their corresponding households were reclassified by the study staff for purposes of uniformity. As a result, some categories used in this report have more than 160 initial patients and households. Many have fewer than 160 initial patients, partially because of the reclassification, but mainly because fewer than the desired number of patients were referred to the individual nurse during the year when field data were collected.

In all, 1,263 households were studied. They included 5,779 members, 2,984 of whom received service from the public health nurse. Forty-two percent of the initial patients in these households were referred for nursing service by various divisions of the health department itself. Private physicians and hospitals referred 22 percent, while the patient or his family accounted for 16 percent. School referrals amounted to 11 percent; all other sources, 9 percent.

For tuberculosis, infant health supervision, and maternity, most referrals came from the health department. The patient and family were also frequent sources of referral for maternity and infant health supervision. Referrals from physicians were more numerous in noncommunicable disease, chronic illness, and tuberculosis than in other categories. The school referrals were mostly of school-age children for physical defects or for behavior or emotional problems.

Index of Additional Patients

Referral of the initial patient in a household has been assumed to lead to service for other members of the family. This is one of the bases for advocating generalized public health nursing service. In this study, service to other members of the households is demonstrated by the ratio of the number of additional patients to the number of initial patients. The resulting index simply describes the average number of added patients per a first referral.

The index of additional patients varies from one service category to another (table 1). When the initial referral was classified as tuberculosis, the index was 2.0 which means that, on the average, 2 patients in addition to the initial patient in the household received service. This was the

highest index. The lowest index, 0.5, occurred when the initial referral was venereal disease.

The magnitude of the index, or the number of additional patients per household, appears to be virtually independent of the size of household and related primarily to the category of the initial patient. For example, households initially admitted as tuberculosis averaged 4 members, 77 percent of whom became patients (index 2.0). In the mental health category, however, households were larger on the average, 4.7 members, but only 38 percent of the members became patients (index 0.8).

The index based on all households and their patients has been omitted purposely from table 1. The households studied were not selected with the view that they would reflect a total caseload. They were selected, instead, to reflect what occurred within a service category. Consequently, all figures derived from the basic data must be considered by category only.

Service Categories of Additional Patients

When service categories were considered separately, additional patients were usually in categories different from that of the initial patient (table 2). The greatest exception was in the tuberculosis category where 82 percent of the added patients were also classified as tuberculosis. This exception is easily understood because the category includes suspects and contacts as well as cases of tuberculosis. Similarly, 58 percent of the additional patients resulting from a venereal disease referral and 42 percent of those from a communicable disease referral were in the same category as the initial patient.

Subcategories in health supervision are determined by the age of the patient. This accounts for most of the additional patients being in a different group than that of the initial patient. For example, only 3.7 percent of the additional patients resulting from an initial referral for infant health supervision were in the same category. This is to be expected. Few households include two infants simultaneously or over a short period of time.

Because of the age factor in health supervision and because child health supervision is usually associated with maternity service, a broader grouping including health supervision

and maternity was made. With these categories grouped, 89.5 percent of the additional patients were in this larger category.

Patient-Nurse Contacts

In previous studies, terms such as interview, visit, and conference have been used to identify

the services given by the public health nurse to or in behalf of the patient. Because specific and often diametrically opposed definitions of these terms have been developed to meet particular needs in various situations, they are not used in this report. Instead, a term "patient-nurse contact" (PNC) has been employed. This term covers all services to or in behalf of the

patient, regardless of the place of service (such as home, office, or clinic), the other person involved (such as patient, social agency representative, or physician), or the means (such as home call, telephone, or letter).

The number of patient-nurse contacts was considered by household, initial patient, additional patients as a group, and individual additional patients (table 3). This table shows that the greatest number of PNC's to a household (24.8) occurred when the initial referral was classified as cancer, cardiovascular disease, or other chronic disease. Also, 87 percent of the patient-nurse contacts in this group were for the initial patient. At the other extreme, only 7.9 PNC's per household were made when the initial referral was classified as venereal disease.

One special point of interest is found in the field of child health supervision. When only the total PNC's to a household are considered, the age of the initial patient makes little difference. When the initial patient was an infant, 11.2 patient-nurse contacts per household were recorded; when a preschool or school child was referred, 11.7 PNC's were made.

In all but three categories (communicable disease, preschool health supervision, and postpartum), the initial patient received more than half of the total PNC's. Furthermore, in all categories except one (postpartum) the average number of patient-nurse contacts to initial

patients exceeded the average number for individual additional patients. In fact, in seven categories, the average number of PNC's to the initial patient was more than double that for individual additional patients. In the postpartum category, the initial patients averaged 5.0 patient-nurse contacts and additional patients, practically all of whom were children, averaged 5.1 (table 3).

Whether reporting under study conditions differs from routine reporting is always a question in any study such as this. A limited answer to this question was obtained by pooling the annual reports of the participating agencies and comparing these data with those of the study. The annual reports provided the number of patient-nurse contacts per patient in the home setting. Similar averages were

Table 4. Home patient-nurse contacts per patient

Category of service	Study	Pooled annual reports
Chronic disease, orthopedic, and noncommunicable disease.....	7.6	8.6

Tuberculosis.....	3.8	1.0
Maternity.....	4.4	3.0
Health supervision.....	3.4	3.2

obtained from the study data on contacts occurring in the home (table 4). A comparison of the several averages suggests that the number of patient-nurse contacts in the home was neither over-reported nor under-reported by the nurses who provided the basic data.

Time for Patient-Nurse Contacts

Time spent in giving nursing service is even more important than the frequency of service in relation to an agency's personnel needs or the setting of priorities within an agency. In this study, nurses reported the time required for actual service. Travel time was excluded because it varies with local geography and means of transportation. The time reported included both preactivity and postactivity as well as the time spent in giving direct service. In other words, total time included that spent in reviewing the patients' records, collecting literature or other supplies, packing nurse's bag, recording on the patients' records, and similar activities, as well as the time spent with the patient.

Time per household ranged from 2.3 hours for households where the initial referral was for venereal disease to 10.7 hours for those where the first referral was for cancer, cardiovascular disease, or other chronic disease (table 5). As might be expected the extremes for time

spent in direct service and in preactivity and postactivity were also found in these two categories, since any direct service requires a certain amount of preactivity and postactivity.

The proportion of time spent in direct service was fairly constant from one category to another, even though there was great variation in the amount of direct service. It ranged from 68 percent in households in the postpartum category to 76 percent in households in the category of cancer, cardiovascular disease, and other chronic disease.

Except for the postpartum and preschool categories, the initial patient received more than half of the time given to the household. The initial patient also received more time, on the average, than any individual additional patient except those in the postpartum category.

Comparison of tables 5 and 3 shows that the difference in the amount of service given to the initial patient and that to the additional patients is even more marked when time is considered rather than frequency of service.

Combination Agencies and Health Departments

Combination agencies have been defined in the National League for Nursing's Public Health Nursing Achievements and Goals as "a service jointly administered and jointly financed by official agencies (including boards of education)

Table 5. Hours of nursing service per household

and voluntary agencies, with all field service rendered by a single group of public health nurses" while health departments are entirely tax supported.

These agencies differ in their policies as to the types and extent of the nursing service they provide.

Combination agencies assume more responsibility for long-term nursing care of the sick and disabled than do health departments. The combination agencies give nursing care of the sick and disabled as part of a continuing nursing service in homes, while health departments usually give such care only on a demonstration basis.

Because of differing policies, the data were examined according to the type of agency providing care (table 6). In general, the 3 combination agencies reported a few more additional patients than did the 5 health departments. Also, with the exception of venereal disease and child health supervision, the combination agencies reported more patient-nurse contacts per household. Finally, more time was spent by the combination agencies per household in every category except noncommunicable disease.

Summary and Discussion

In this study of 1,263 households and the public health nursing service they received,

three measurements have been used to describe the amount of service that ensues in a household as a result of the referral of the first patient. The first was the average number of additional patients per initial referral. This index was found to vary considerably with the service category of the first patient, and also appears to be virtually independent of the household size. In all service categories except tuberculosis, fewer than two additional patients were served per initial referral.

The second measurement was the number of patient-nurse contacts per household; the third, the number of hours spent in nursing service per household. Both of these measurements varied with the category of the initial patient and the variation was somewhat the same for the two measurements. This consistency in the variation was closely related to the fact that in most categories the initial patient received the majority of the patient-nurse contacts and the greater proportion of the time expended.

Time spent in preactivity and postactivity was studied as well as time spent in direct service to the patients. In all categories indirect service accounted for approximately 25 percent of the time expended, indicating that actual time with a patient or household is not the best measure for a work unit. A better one also takes into account the time spent for indirect service.

The study staff made an effort to select those agencies and nurses that represented good public health nursing practices. If this was accomplished, the data presented in this report might be used in estimating personnel needs.

Radioactivity Study

Milk samples have been analyzed for specific radionuclides in a continuing study conducted by the Public Health Service in milksheds serving Sacramento, Salt Lake City, St. Louis, Cincinnati, and New York City. Analyses to date find that manmade radioactivity on the average is but a small fraction of the recommended permissible maximum and is but slight even in relation to the natural radioactivity of milk. The study, which began in April 1957, is part of the Service's broad program in environmental analysis, including tests for radioactivity in water, air, and food.

Milk was the food selected for the initial study because of its importance in the diet and its year-round and widespread production. Radiation may be measured as a total or gross level, or it may be broken down to show the level of radiation from each specific radioactive element. Specific measurements, although much more difficult to make, are important because health effects vary greatly among specific elements. In addition, because milk normally contains natural radioactive potassium, the study undertook the separate measurement of radiation from specific manmade nuclides.

With the cooperation of State and municipal health agencies and the dairy industry, a monthly 1-gallon sample is collected at a designated point in each milkshed. The sample is a composite of a day's delivery by a group of dairy farms.

The sampling points were set up by the Service's

regional milk and food consultants in accordance with the following criteria:

- The milk in each composite sample must be from a group of farms having, altogether, at least 1,000 cows.
- The number of individual farms in the sample must be small enough to make collection of field data on each farm feasible.
- The composite milk sample must be from a supply that is part of a major metropolitan milkshed.
- The conditions under which the milk is received must be such that milk from the same production area is represented in the composite sample collected each month.

Collateral information also is collected concerning feeding practices, water supplies, and breeds of dairy cattle typical of each area.

The average levels of radioactivity found in samples collected during the first year of the pilot program are expressed here in units of micromicrocuries per liter of milk. A curie is a measure of radioactivity equivalent to that produced by one gram of radium, and a micromicrocurie is one-millionth of a millionth of a curie. The levels are shown in the table.

Additional sampling points are being established in the milksheds serving Atlanta, Ga.; Fargo, N. Dak., and Moorhead, Minn.; Austin, Tex.; and Spokane, Wash; and in a milkshed in southern Wisconsin.

First year's average levels of radioactivity in milk samples (micromicrocuries per liter)

¹ Total whether or not reinstituted.

² Most recently available population figures were used regardless of the year that fluoridation was instituted.

during 1957. During the same year, 3 communities, providing water to 66,000 people, reinstituted the measure after having previously discontinued it. During the years 1945 to 1957, a total of 94 communities discontinued fluoridation; of these, 13 reinstituted the measure (table 3).

Water supply systems are publicly owned in 84 percent of the communities in which the fluoride content is controlled. In cities with more than 500,000 people, 100 percent of the water systems are under public ownership. Eighty-eight percent of the systems are publicly owned in cities of from 25,000 to 500,000 population, 90 percent in places from 10,000 to 25,000, and 82 percent in places under 10,000.

Future Growth

The major increases in the population provided with fluoridated water during the next few years is likely to be in the larger cities. However, in the more distant future the greatest increase will probably be in the smaller places where today only 5 percent have fluoridation programs. It is in towns of 2,500 or less that fluoridation will need to make its greatest advances.

Although fluoridation continues to be a mat-

ter of public discussion in certain parts of the country, there has been a decline in the number of communities discontinuing fluoridation over the past several years. The number of water supply systems discontinuing fluoridation in 1954 to 1956, for example, was 3 to 5 times greater than in 1957.

Interest in fluoridation programs in other countries is mirrored in the endorsements of re-

Figure 2. Percentage of communities fluoridating their water supplies, by size, December 31, 1957.

Status of Controlled Fluoridation in the United States, 1945-57

OF THE approximately 118 million people in the United States provided water by community water supplies in 1957, 40.3 million (or about 1 in every 3 persons) in 3,534 communities drank water containing the minimum or higher level of fluoride recommended for optimum dental benefits.

Of these 40.3 million persons, 33.3 million in 1,631 communities are supplied water in which the fluoride level is controlled, and 7 million in 1,903 places use water naturally containing 0.7 ppm or more fluoride. Since 1950, the number of persons using water with a controlled fluoride content has increased by about 32 million (table 1 and fig. 1).

Controlled Fluoridation

Fluoridated water is provided for a greater proportion of people living in large cities than in smaller communities (table 2). A majority of the Nation's cities having populations of a half million or more (12 of the 18) provide fluoridated water. These cities are:

Chicago, Ill.	San Francisco, Calif.
Philadelphia, Pa.	Pittsburgh, Pa.
Baltimore, Md.	Milwaukee, Wis.
Cleveland, Ohio	Houston, Tex.
St. Louis, Mo.	Buffalo, N. Y.
Washington, D. C.	Minneapolis, Minn.

Two of the five cities with populations exceeding 1 million (Chicago and Philadelphia), and 9 of the 13 cities with populations ranging between a half million and a million have in-

stituted fluoridation. Of these 13 cities, only one, Houston, Tex., provides water which naturally contains fluoride at a level of 0.7 ppm.

Of places with less than a half million population, 32 percent of those with a population between 10,000 and 500,000, 17 percent between 2,500 and 10,000, and 5 percent under 2,500 have fluoridation programs (fig. 2).

The authority by which fluoridation is instituted is of interest. In 62 percent of the cities fluoridating, the governing body of the community authorized adoption of the measure. In 5 percent authority to fluoridate was obtained by referendums, and in 4 percent the utilities commission authorized the measure. Nine percent of the communities did not specify authority or used other procedures in adopting fluoridation.

Fluoridation was discontinued in 13 communities providing water to 192,000 people

A 1955 study demonstrates that the mere introduction of a highly virulent strain of poliomyelitis into a susceptible population is not enough to kindle a severe epidemic.

Poliomyelitis in Idaho After Use of Live Virus Vaccine

CARL M. EKLUND, M.D., E. JOHN BELL, Ph.D., and ROBERT K. GERLOFF, M.A.

FACTORS responsible for a poliomyelitis epidemic in the United States are not clear. Sporadic cases of poliomyelitis are reported every year and may be present at any season throughout the country. Epidemics, however, are geographically limited and are relatively infrequent. They have no apparent regularity but generally occur during the summer and early fall. It would appear that an epidemic should follow introduction of an especially virulent and invasive strain of poliovirus into a relatively susceptible population, but in an endemic area, it is not possible to establish the origin or introduction of such a strain.

An incident in Idaho during April 1955 gave an unparalleled opportunity to study a poliomyelitis outbreak. In that month two lots of commercially prepared vaccine were used to

immunize 32,000 children in the school program of the State. After the first series of inoculations, poliomyelitis appeared in the vaccinated children, and the immunization program was terminated. Subsequently, viable poliovirus of all three types was shown to be present in the vaccine lots used (1). The introduction of viruses into a human population at a known time and the ease with which subsequent events could be followed created a favorable environment for study of the epidemic.

Vaccine containing live virus was given at a time when poliomyelitis did not constitute a problem in Idaho. The vaccination program was conducted at least 2 months prior to the season when an increase in incidence would have been expected on the basis of past experience. Thus, polioviruses were introduced into a relatively susceptible population at a season which experience had shown to be unfavorable for the natural occurrence of poliomyelitis epidemics.

Idaho's first recorded poliomyelitis epidemic was in 1947, when 371 cases were reported. Other epidemics occurred during 1949 (510 cases) and 1952 (253 cases). In a population of approximately 600,000 people, 1,884 cases were reported during the 8-year period from 1947 through 1954.

Our conclusions regarding conditions necessary for the occurrence of a poliomyelitis epi-

Figure 2. Poliomyelitis, type 1 and probable type 1, among contacts of children vaccinated on or after April 17, 1955, Idaho.

paralysis appears. Although no specimens were received from 25 paralytic patients, the majority of these cases were considered to be due to type 1 virus since so few type 2 and type 3 poliovirus were isolated from patients in Idaho during 1955.

Poliomyelitis occurred in 20 children who received vaccine, in 61 persons who were contacts of vaccinated children, and in 86 individuals who did not have a history of contact with vaccinated children or who had onset of illness during July or later. When onset was after July 1, 1955, the time lapse since vaccination

demic are based primarily on data concerning the incidence of poliomyelitis in the recipients of two lots of vaccine used in Idaho, the infectivity of those individuals manifesting clinical disease, and the number of secondary cases that developed.

Methods

Attempts were made to obtain clinical and epidemiological data and selected specimens from all cases of poliomyelitis reported from the time of administration of the vaccine until January 1, 1956. Whenever possible, specimens were collected from family associates of patients with onset before October 1955. Blood specimens for serologic studies also were collected from 657 children in first and second grades 6 to 8 weeks after vaccination.

All specimens were examined by standard tissue-culture techniques in which epithelial cells from the kidneys of rhesus monkeys were used. Viruses were isolated in such cultures by inoculation of suspensions of certain tissues, sputum, or feces into bottles or tubes containing sheets of cells which had been incubated at 37° C. for 7 days. Agents producing typical cytopathogenic effects were identified by neutralization tests (2) with serums which had been produced at the Rocky Mountain Laboratory and used in a portion of the study conducted by the National Foundation for Infantile Paralysis during the evaluation studies in 1954. These examinations were made in the

same laboratory that had conducted the evaluation study in Montana in 1954.

Samples of the two lots of vaccine used in Idaho were supplied by the Idaho Department of Public Health, district health department directors, practicing physicians, and, in the case of one lot, also by the manufacturer. Monkeys and special tissue-culture methods were used to detect virus in these vaccines (1).

The number of cases accepted for inclusion in the study and the criteria for their selection are given in table 1 and figures 1-7. All paralytic cases with clinical data compatible with a diagnosis of poliomyelitis have been included. In some cases, however, no specimens were submitted for examination. Nonparalytic cases were excluded unless virus was isolated from specimens collected from the patient or from a family contact.

Of 167 cases accepted as caused by type 1 poliovirus, 149 were paralytic and 18 were nonparalytic. Virus was isolated from 97 patients and from 12 family contacts. Eighteen persons from whom virus was isolated did not display evidence of paralysis, whereas 91 manifested some degree of paralysis. In 33 instances in which virus was not isolated, diagnosis was based on the presence of diagnostic titers of type 1 antibodies. In the majority of cases a rise in antibody titer was not demonstrated. These cases are included, however, since it is well known that the immunological response is already far advanced by the time

¹ In all cases type 1 antibodies were present either alone or in conjunction with types 2 or 3 antibodies.

² These cases are included as probable type 1 poliomyelitis since there were so few isolations of type 2 or type 3 poliovirus from cases.

So far as can be determined, about the same amount of each of the two lots was used. A diagnosis of poliomyelitis was accepted in 20 of these children (an attack rate of 62 per 100,000); 17 of them suffered paralysis (a paralysis attack rate of 53 per 100,000), and 4 died (a rate of 12 per 100,000).

Although the paralytic attack rate was high for such a widely scattered population, it was much below that observed in some outbreaks of poliomyelitis spread by natural means among populations with a previous history of poliomyelitis. In Minnesota during the summer of 1952, the paralytic attack rate among children of comparable ages was 182 per 100,000, and the death rate was 17.2 per 100,000.

In addition to clinically recognizable poliomyelitis, minor febrile illnesses occurred among children who received the vaccine. However, since vaccination was carried out at a time when respiratory illnesses were prevalent, it was difficult to relate minor illness to the use of vaccine. Approximately 20 percent of 649 vaccinated children complained of minor illnesses that occurred 1 to 2 weeks after vaccination. The illness consisted chiefly of headache, fever, general aching, and occasionally sore throat, nausea, or vomiting.

A relationship between these minor illnesses and the administration of vaccine was suggested when the antibody titers of the group with the minor illnesses were compared with those of vaccinated children who did not become ill. Since 6 percent of the children in each group did not possess antibodies to any type, they are excluded in this analysis. Children with minor febrile illnesses had a significantly greater proportion of type 2 antibody titers of 1:64 or less than the group without illness.

Type 2 antibody titers were distributed among 144 vaccinated children with minor illness and 463 children with no illness in the following manner:

	Minor illness (percent)	No illness (percent)
1:256 or greater.....	36	53
1:64 or less.....	64	47

In the group with type 2 antibody titers of 1:256 or greater, 37 percent had an anti-

body titer of 1:256 or greater for all 3 types; 85 percent for 2 types, and 15 percent for 1 type only. The corresponding figures for the group with a type 2 antibody titer of 1:64 or less were 0 percent, 25 percent, and 50 percent. Approximately 25 percent had a high type 1 antibody titer alone, 25 percent a high type 3 antibody titer alone, and 25 percent both type 1 and type 3 antibodies in high titer. These findings suggest that among individuals who had had no previous experience with type 2 virus, infection with type 1 or type 3 virus might be associated with the symptoms of a minor febrile illness.

That type 1 virus may have been more important than type 3 virus in causing minor illness is suggested by an examination of the group of serums with type 2 antibodies in a titer of 1:256 or greater. Eighty-one percent of the group with minor illness had type 1 antibodies in a titer of 1:256 or greater, whereas 65 percent of the group with no illness possessed such titers. This difference is statistically significant ($P=.022$) and suggests that type 1 infection even in the presence of high type 2 antibody titer may at times cause minor illness. A significant difference was not found in the proportion of high type 3 antibody titers between the two groups.

Many minor illnesses apparently were not caused by infection with a poliovirus since 18 children with minor illnesses either had no antibodies or had antibodies for 1 or 2 types of virus in a titer of 1:8.

Contacts of Vaccinated Children

In 61 instances of poliomyelitis, a history of contact with vaccinated children was obtained. Children under 15 years of age and women were chiefly affected (table 2). Multiple cases occurred in some families. In 56 instances a vaccinated child, usually with no recognized illness, appeared to be the source of infection. Poliomyelitis was diagnosed in only 2 of these vaccinated children and 4 others manifested symptoms of a minor febrile illness.

The number of days from the vaccination of a child suspected to be a carrier to the onset of illness in the 61 contact cases is given in table 3. This period was less than 45 days in 54 instances. When greater than 64 days, a history

was so long that it appeared unreasonable to attribute the illness to contact with a vaccinated child.

Results

Epidemiological and clinical evidence showed a relation between the injection of poliomyelitis vaccines and the subsequent occurrence of poliomyelitis. Vaccination was begun April 17 and was practically completed within 5 days. Poliomyelitis was first reported in vaccinated children (fig. 1) in various scattered areas throughout the State (fig. 1, map A). These cases were followed by another group of cases (fig. 2, map B) limited to contacts of inoculated children. The geographic distribution of the two groups was similar. Although considerable effort was made to detect other types of poliovirus, only type 1 was isolated from these patients.

In 12 of 17 children with paralytic disease, the first evidence of paralysis was seen in the inoculated arm. In one child, the first signs, which developed on the 18th day after vaccination, were those of bulbar involvement and weakness of neck muscles. Of the 10 cases occurring within a week after administration of vaccine, 9 had onset of paralysis in the inoculated arm and 1 in a leg. In 5 of the 9, the disease progressed to bulbar poliomyelitis, and 1 child developed symptoms of severe encephalitis.

Initial involvement of an upper extremity with rapid progression to the opposite extremity and respiratory muscles was so unique clinically as to suggest that host response to poliovirus was influenced in some unusual manner. Equally striking was the lack of evidence of infection in members of patients' families when onset was less than 7 days after administration of vaccine.

Specimens were submitted from 31 family contacts (14 children) of the 7 children with onset on the fifth and sixth days after inoculation, but virus was not detected in any family contact nor was a rise in antibody titer demonstrated. Virus was first isolated from a family contact when the incubation period was 7 days. In two instances, virus was not recovered from family contacts when the incubation period was as long as 10 days. Usually,

proliferation of poliovirus takes place in the upper and lower digestive tracts before the central nervous system becomes involved, and the person is eliminating virus before symptoms recognizable as poliomyelitis occur. Furthermore, members of the family usually are found to be carrying poliovirus in their intestinal tracts by the time the initial case of poliomyelitis is diagnosed. However, in the vaccinated children in Idaho, virus apparently did not reach the intestinal tract until after the appearance of signs pointing to disturbances of the central nervous system. This observation and the fact that poliovirus was not recovered from family contacts of seven patients indicated an unnatural spread of the virus.

Several observations suggested that live poliovirus was present in the two lots of vaccine used: the time relationship of cases to the administration of vaccine, the wide geographic distribution, the frequent occurrence of initial paralysis in the inoculated arm, and the absence of evidence of poliomyelitis infection in the families of patients in whom there was a short interval between inoculation of vaccine and onset. Therefore, attempts were made to determine the amount of such virus in these lots.

By using cortisone-treated monkeys, all three types of poliovirus were isolated from each lot of vaccine. The available amount of one lot was insufficient to permit repeated attempts to isolate virus, but sufficient vaccine of the second lot was available for such tests. With this lot, the maximum number of monkeys infected with types 1, 2, and 3 poliovirus, respectively, was 4 of 10, 3 of 10, and 2 of 7. The maximum number of inoculated monkeys paralyzed in any experiment was 4 of 7.

Treatment of poliovirus with 1:4,000 formaldehyde at 37° C. for several days must produce many complex changes in the viruses, and any attempt, with present knowledge, to determine the amount of virus in such a preparation must represent only a crude estimate. Detailed findings of experiments in monkeys with these vaccine lots will be given in another report.

Reactions to the Three Viruses

Approximately 32,000 children received vaccine in the school program during April 1955.

may have been exposed to poliovirus from Idaho cases.

Detection of Types 2 and 3

Type 2 poliovirus was not isolated from children receiving vaccines in Idaho or from their immediate contacts. However, type 2 virus was isolated from the family of a child whose paralytic disease began July 5 and from one patient with nonparalytic poliomyelitis with onset August 23. Serologic studies of 6 other patients with paralytic poliomyelitis showed significant antibody titers for type 2 virus. In

55-59	1	59	1	30
60-64	2	61	0	30

of association with vaccinated children was much less frequent, and a carrier other than a vaccinated child was considered to be the source. Periods as short as 16 days between administration of vaccine and onset of illness in an exposed person were observed, and in 6 instances the period was less than 20 days. Such short intervals between vaccination and onset in a contact suggest that several cycles of infection could take place within a 60-day period. It is therefore possible that some of the 61 so-called contact cases are not the result of exposure to the suspected vaccinated child but represent a cycle of infection further removed. It was impossible to designate a definite period during which contact cases could be attributed only to exposure to a vaccinated child.

Cases of poliomyelitis that occurred in Idaho later than 64 days after the vaccination program was terminated were arbitrarily classified as secondary cases. Type 1 poliovirus was isolated from 2 vaccinated children with whom poliomyelitis patients had had intimate contact, but the time of onset was 81 and 83 days, respectively, after vaccination. Whether these children were carrying virus from the time of vaccination or had become infected subsequently is uncertain.

If cases having a history of association with vaccinated children and onset within 64 days after the time of vaccination are accepted as contact cases, a carrier rate of 178 per 100,000 is obtained.

Other Associated Cases

Poliomyelitis occurred in 86 persons whose contact with a vaccinated child did not appear to be the source of infection but in whom type 1 poliovirus was shown to be the cause, or most probable cause, of illness. As shown in figures 3-5 and table 4, the disease occurred in some of these at the same time as it did in those having intimate contact with vaccinated children. Usually, however, onset was so long after the time of vaccination that poliomyelitis due to exposure to a vaccinated child did not appear probable.

As noted in figures 3-5, 19 cases occurred during each of the three 30-day periods from July 1 to September 28, but the number then fell to approximately 7 during the 30-day periods between September 29 and December 28. Probably these cases represent at least the third cycle of infection following the use of vaccine, since they began to appear immediately following the occurrence of known contact cases and occurred in areas where vaccinated children developed poliomyelitis.

Twelve poliomyelitis patients, 11 paralytic and 1 nonparalytic, were admitted to Idaho hospitals from adjoining Malheur County, Ore. Type 1 poliovirus was isolated from nine patients. Onset of the first case was August 24; of the last, October 28. An adjacent Idaho area, in which several cases of poliomyelitis occurred, is a trading center for the Oregon county. It appears possible that these patients

cent of these children, a limited spread of type 1 virus during the summer and fall of 1955 is indicated.

The antibody titers of blood specimens from children who had received vaccine in 1955 and from those who had served as controls in vaccine studies in Idaho in 1954 were compared for each of the three types of poliovirus. Although titrations of the 1954 serums were performed in the poliomyelitis evaluation laboratory at the University of Oregon Medical Col-

lege, Portland, the data are considered to be roughly comparable. More children in the 1955 group had titers of 1:1,024 or higher against each of the viruses, whereas a lower proportion had a serum titer of less than 1:8 (table 5). Since serums of approximately 30 percent of the children vaccinated in 1955 had no appreciable titer against type 1 and type 3 viruses, these children apparently were not infected by the amount of viruses present in the vaccines (table 6). Antibody responses to three doses of vac-

3 of these persons, the onset occurred during July (fifth, seventh, and eighth), 1 during August, 1 during September, and 1 during October. Three patients (2 male and 1 female) were in the age group 0 to 9, 1 patient (female) in the age group 10 to 19, and 4 patients (1 male and 3 females) in the age group 20 to 24. It was not possible to establish that the vaccine was the source of infection in these instances (fig. 6).

Although clinical poliomyelitis due to type 3 virus was not demonstrated in vaccinated children or in their intimate contacts, the possibility that minor illnesses resulted from injection of this virus cannot be excluded. A high neutralizing antibody titer for type 3 poliovirus and low or no neutralizing titers for the other two types of poliovirus were obtained from blood specimens of 21 children who gave a history of minor illness 6 to 8 weeks after vaccination.

Scattered cases of poliomyelitis caused by type 3 virus occurred in Idaho late in the summer. On nine occasions, diagnosis was established by isolation of virus either from patients or from members of the patient's family. In addition, only type 3 antibody was found in the serum of one paralytic patient from whom virus was not isolated. In this group of 10 patients, 4 had onset in July, 4 in August, 1 in September, and 1 in December (figs. 6 and 7). The earliest date of onset was July 9.

Five patients (3 male and 2 female) were in the age group 0 to 9, 3 (1 male and 2 female) in the age group 10 to 19, and 2 males in the age group 25 to 34. The sex and age distribution, the time of onset, and the geographic distribution did not suggest a connection with use of the vaccine.

Antibody Levels

During the vaccine study conducted in late 1955 and early 1956, blood specimens were obtained from 480 nonvaccinated individuals, chiefly children, and the levels of antibodies against specific types of poliovirus were determined at the Rocky Mountain Laboratory (table 5). Since the antibody level for type 1 poliovirus was less than 1:8 in 53.5 percent and was 1:1,024 or greater in only 1.2 per-

immune status of a population and to season of the year is inadequate to explain the epidemic occurrence of poliomyelitis.

Strangely, viable types 2 and 3 polioviruses present in the vaccine did not cause disease in vaccinated children or spread to their contacts. This could be due to a lack of virulence of these viruses for human beings when given intramuscularly or to interference between strains when administered simultaneously to susceptible individuals. The presence in vaccinated children of high antibody titers for types 2 and 3 polioviruses, however, suggests that these strains proliferated. The absence of central nervous system disease due to infection with type 2 and type 3 strains demonstrates the inability of these strains to invade the central nervous system following intramuscular inoculation. In monkeys, these strains, particularly type 3, showed little ability to produce viremia or to proliferate in peripheral tissues, characteristics which may be related to absence of disease in vaccinated children. The type 1 strain, which was definitely virulent for children, frequently was isolated from blood and peripheral tissues of monkeys. A type 1 strain without these characteristics appears desirable for use in a vaccine.

Summary

In Idaho, with a population of approximately 600,000, two lots of poliomyelitis vaccine were used during April 1955 to vaccinate 32,000 children in the first and second grades. All three types of poliovirus were isolated from

these lots of vaccine. Poliomyelitis due to type 1 virus occurred in 20 vaccinated children and in 61 of their contacts. In addition, 86 persons developed poliomyelitis from possible contact with these two groups. Thus, 167 cases were associated with the use of these two lots of vaccine. Poliomyelitis due to type 2 or type 3 viruses was infrequent, and evidence relating infections with these types to the vaccine used was not obtained. The absence of a severe outbreak of poliomyelitis due to type 1 virus is noteworthy in view of the wide dissemination of a virulent strain of type 1 poliovirus throughout the State. Since the immunity of the population was rather low as indicated by the previous history of poliomyelitis and by the 1954 vaccine evaluation study, a more severe outbreak would have been expected. Factors in addition to virulence of a poliovirus strain and immune status of a population are yet to be discovered before the genesis of poliomyelitis outbreaks can be explained adequately.

U. S. Medical Supply Stocks Surveyed

A survey of the Nation's supply of medical items essential to survival following nuclear attack is being conducted by the Public Health Service. With the cooperation of the pharmaceutical industry, more than 700 wholesale drug houses, surgical supply firms, and chain drugstore warehouses will be covered in the survey, which is part of a program set up by the Office of Defense Mobilization. Also participating in this program are the Business and Defense Services Administration of the Department of Commerce, the Federal Civil Defense Administration, and the Department of Defense.

cine with "good" antigenicities reported in the 1954 study (3) and of vaccine used in Idaho in 1955 are compared in table 6.

Antibody distribution for children vaccinated in 1954 is well illustrated by the results obtained through neutralization of type 1 po-

liovirus (table 6). The discrepancy between the proportion of children having intermediate titers in the group vaccinated in 1955 and the proportion in the group vaccinated in 1954 is what would be expected from administration of live virus. Individuals either developed infection and as a result produced antibodies in high titer or failed to become infected and consequently produced no antibodies.

Table 6. Antibody levels after 3 injections of "good" vaccine lots in the 1954 poliomyelitis evaluation study of NFIP compared with those developing after a single injection of vaccine containing live virus

Discussion

It is rather surprising that the intramuscular inoculation of a virulent strain of type 1 poliovirus, which was capable of spreading from person to person, did not give rise to a more severe epidemic. The population had a large number of susceptible individuals, as indicated by antibody studies before and after administration of the vaccine and by the past history of poliomyelitis in the area. Vaccine was given in the spring when the weather was cold, but type 1 virus was still present in the population later in the summer. Yet an increase in the incidence of poliomyelitis did not occur. Consequently, one must conclude that a simple relationship of virulence of virus to

Committee Members

Members of the Committee for Review and Evaluation of Research and Development Positions are Dr. Frederick J. Brady, program officer, Bureau of State Services, chairman; Dr. George H. Bradley, assistant chief, Communicable Disease Center; Dr. Keith H. Lewis, chief, Milk and Food Research Program, Robert A. Taft Sanitary Engineering Center; and Dr. Herbert E. Stokinger, chief toxicologist, Occupational Health Branch, Division of

Special Health Services. H. N. Meng, Division of Personnel, Office of the Surgeon General, serves as the committee's technical adviser; Lambert G. Longen, Executive Office, and Harold F. Eisele, Program Office, Bureau of State Services, are its staff assistants. Dr. John C. Cutler served as chairman prior to his transfer to the National Institutes of Health as assistant director, National Institute of Allergy and Infectious Diseases.

their work reviewed comprehensively by members of their own scientific discipline.

The results of the Survey of Attitudes of Scientists and Engineers in Government and Industry, conducted by the Committee on Engineers and Scientists for Federal Government Programs, may reflect significantly the Bureau's reviews. The survey found that 65 percent of the scientists in the Bureau were satisfied with their job classification, as compared with 52 percent of those queried

throughout the Federal Government. Fifty percent of the Bureau scientists, and only 37 percent of the entire Government, believed their positions offered sufficient opportunity for salary advancement.

The Bureau's system has strengthened its scientific research and development, provided program administrators with classification and utilization reviews suited to their organization, and assured the scientist of a technically broad appraisal of his job.

Research Grant for National Library of Medicine

The Council of Library Resources has granted the National Library of Medicine \$73,800 to study methods of improving bibliographic services through the use of mechanical equipment.

The primary aim of this research project will be to develop improved methods for the rapid and efficient publication of comprehensive periodical literature indexes in broad subject fields.

To accomplish this goal, new composition techniques based on an integration of photographic and data-processing equipment will be investigated.

If the project is successful, the resultant changes in format and manuscript preparation will be adopted with the 1960 issues of the *Current List of Medical Literature*.

Appraising Scientists And Their Jobs

RICHARD W. BUNCH

IN THE INTEREST of properly appraising the scientists in its employ, the Bureau of State Services, Public Health Service, has devised a system for reviewing research and development positions.

Anyone who has had experience in grading research positions has faced the problem of finding criteria for measuring the quality of performance, a factor which materially affects the grade of the position.

The usual standards of job evaluation and measures of workload and accomplishment may be difficult to apply. The number of the scientist's publications may be quite misleading because years of preliminary unpublished trials may precede consequential results. The scientist is inclined to believe that a position classifier not trained in his specialty cannot satisfactorily evaluate his job. These considerations caused the Bureau of State Services to seek a better method of classifying scientists.

The Bureau uses scientists of many professions and disciplines in helping States and communities prevent and control disease and maintain health. Its programs include control of venereal disease, tuberculosis, and other communicable diseases; heart disease; chronic illness and aging; dental public health; air pollution control; water supply and water pollution control; milk and food sanitation; radiological health; and international health. Often its scientific personnel, by the nature of their jobs, are isolated from colleagues or supervisors trained in the same disciplines.

To enhance the job status of these men and women, the Bureau in 1955 formed the Committee for Review and Evaluation of Research and Development Positions to appraise, within the framework of civil service regulations, individual scientists and their achievements. The

committee's reviews, repeated at intervals of approximately 2 years, cover all scientists in grades GS-11 and above in research and development positions.

Basic to the committee's evaluations is the concept that, in determining the proper grade and salary of such positions, it is difficult to separate the job and the incumbent. The scientist's background, experience, professional capabilities, and achievements cannot be disregarded. In research and development work, the individual tends to create the level of his assignment by the quality of his research contributions. The grading of such positions must necessarily be related to the qualifications the individual brings to the position as well as to the nature of his duties and responsibilities.

A scientist's peers, who are themselves leaders in a field, can best evaluate his work, the committee believed. Consequently, panels of 3 or 4 peers from Public Health Service bureaus, other Government agencies, universities, and private industry have been appointed to work with the committee. The committee, with the help of these panels, applies standards used in governmental and nongovernmental positions to classify salaries and recognize scientific achievement.

Within the Bureau, the committee and its various panels of specialists have reviewed approximately 150 positions, covering all civil service scientists engaged in research and development activities. These included 32 in bacteriology-microbiology, 24 in other biological sciences, 37 in chemistry, 39 in statistics, 12 in behavioral sciences, and 6 exempt positions as provided in the Public Health Service Act, section 208 (g).

In addition to recommendations on the pay levels and classification of individual scientists, these reviews have yielded valuable counsel on better utilization of scientific skills and the need for special training and changes in assignment to round out professional experience.

The committee's recommendations and supporting statements from the panels of professional peers provide the Bureau and division chiefs with an adequate evaluation of the contributions of staff members whose professional training may have differed from their supervisor's. And for the first time, scientists have

Mr. Bunch is executive officer, Bureau of State Services, Public Health Service.

Many technical and practical problems are encountered when a rigorous evaluative study is attempted. This paper will not discuss them. Instead, we shall consider how certain decisions about the research design and how certain problems that arise in executing the research within an operating program restrict the interpretation of the findings. Using a recent effort to evaluate the effectiveness of a rehabilitation program for posthospitalized mental patients as an illustration, we shall examine in particular the limitations imposed on the definition of what is being evaluated.

The Altro Project

The specific rehabilitation program that was subject to our evaluative investigation was that of the Altro Health and Rehabilitation Services, Inc., located in the Bronx, N. Y.

For more than 40 years Altro has operated a sheltered workshop for tuberculous patients, and it has served cardiac patients for more than 6 years (11, 12). After extended periods of hospitalization, these patients come to the Altro workshop where they remain, on the average, about a year before they graduate. They work in a factory environment but with work pressures adjusted to their health rather than to the demands of production. The workshop is, indeed, a modern garment factory manufacturing uniforms for nurses and hospital gowns that are sold by a sales force on the competitive market. Patients are paid union scale wages at piece rates for goods produced. They are subsidized when necessary to permit them to remain in the rehabilitation program.

The patients are under close but unobtrusive medical supervision; they are provided with periodic health examinations and continuous convalescent treatment when required. All patients put in a full day, but the actual time each works is determined by his particular needs. Work and rest periods alternate in recognition of disability and the development of work tolerance. Supervisors in the factory and instructors in the office-training program are practiced in dealing with the special problems of posthospitalized patients and many are themselves graduates of Altro. Each patient is assigned a caseworker and other social services

are available such as vocational counseling, job placement, and educational assistance.

The program is intended to harden the patient so that his transition from hospital to demands of normal living will not be so abrupt as to threaten his recovery and precipitate rehospitalization. By letting patients test the limits of their capacities in its workshop, Altro hopes that its clients will learn to function independently in the community.

From restrospective studies there is evidence that Altro makes an effective contribution to the rehabilitation of tuberculous and heart patients (13, 14).

With the need of tuberculous patients for rehabilitation services decreasing, and with the cardiac program well established, Altro turned its interest to the inclusion of psychiatric patients. In 1953 Altro began a year of experimental collaboration with Hillside Hospital, a private mental hospital in New York City (15). Ten patients were referred to Altro by Hillside, and seven participated in the workshop. With this experience added to the years of serving other types of patients, Altro felt ready to extend its services tentatively to certain types of hospitalized mental patients from the more heterogeneous populations of State hospitals (16). It did so with the widespread encouragement of psychiatrists and other professional persons concerned with mental health. Indeed, throughout discussions of potential sources for the limited number of patients that Altro felt able to serve, the director of Altro was repeatedly assured that this sort of rehabilitation service was greatly needed in the psychiatric field and that there would be strong demand for it.

With such assurances, arrangements were concluded with the New York State Department of Mental Hygiene for exploring the value of this service to patients of its Bronx aftercare clinic. Financial support was obtained to extend Altro's program, and the Russell Sage Foundation gave financial assistance for an evaluation of this effort. In accepting such assistance, Altro committed itself to a control-group design as an evaluative requirement. The patients were to be assigned at random to the experimental and control groups. The research question could therefore be stated at the outset as fol-

Study of the Alto Health and Rehabilitation Services' program for rehabilitation of posthospitalized mental patients illustrates some requirements for evaluative research in mental health. Limitations imposed by control group designs and selective biases arising from the operation of the program are taken into account.

Evaluating a Rehabilitation Program for Post-Hospital Mental Patients

HENRY J. MEYER, Ph.D., and EDGAR F. BORGATTA, Ph.D.

INTEREST in rehabilitation services for posthospitalized psychiatric patients has been stimulated by an increase in release rates from hospitals, following introduction of drug therapies, and by wider recognition that family, employment, and other social conditions appear to affect successful adjustment in the community (1-4). This interest may be thought of as a counterpart to the even greater attention paid to preventive programs (5).

Whether programs are directed toward prevention or rehabilitation, claims for their efficacy inevitably raise the question of evaluation. In the interest of efficiency as well as economy, sound assessment of effectiveness is obligatory for those who promote these programs as contributions to mental health. The need for evaluative research is widely acknowledged (6). But evaluative research on a service program in the field of mental health is, as

Clausen has said, "so appealing and yet so hazardous" (7).

Because of the pressing need to evaluate programs in which much time, effort, and money have been invested, most studies fall short of the rigor expected of scientific research. This is understandable in view of the difficulties of evaluating complex, changing, and often experimental efforts. Studies of the staff's or clients' satisfaction with a program, subjective judgments about progress or change, case studies to illustrate success, and similar reports may contribute useful knowledge about the operations of a program and may be valid sources of insight and understanding. But it is of no help to the orderly development of scientific knowledge to accept these studies as demonstrations of success or failure when it is possible to attempt more rigorous research. The state of our ignorance and the means of overcoming it should be accepted so that we may proceed slowly, and often painfully, to gain secure knowledge of what is being accomplished. The conclusion that this is the way of progress in evaluative research has been recognized not only for programs directly concerned with mental health but also for related fields, such as social casework, prevention of delinquency, and education of parents (8-10).

Dr. Meyer is professor of sociology and social work at the University of Michigan, Ann Arbor. Dr. Borgatta is associate social psychologist at the Russell Sage Foundation and adjunct professor of sociology at New York University. This paper was presented in somewhat different form at the annual meeting of the American Sociological Society in Washington, D. C., on August 27, 1957.

we want to know what Altro achieves only through its treatment services, we would have to compare those who went through the program with patients who might have gone through if they had had the opportunity. Still undefined would be which of the many things included in the rehabilitation program produced given results for experimental cases as compared with control cases.

It is conceivable that the treatment experiences for the experimental group could be recorded in detail at all points after their selection. In this manner specific treatment efforts might be related to variations in the degree of success or failure observed after treatment. It would be necessary, however, to have similar detailed knowledge of the experiences of the comparison group. Some of the features of the rehabilitation program at Altro, sympathetic work supervision, for example, might well be present in the experiences of patients in the control group.

Similarly, the effectiveness of any one of the specific kinds of treatment services could be stated only if the method of assignment to receive different services was governed by a random rather than a selective procedure.

For this particular evaluation the population was defined as patients who accepted the invitation to enter the Altro program. Among such, the treatment and comparison groups were selected at random and our generalizations must apply only to this population. The point here is that the design limited generalization to a segment of the population that might provide the answer to the question: Is Altro effective in rehabilitating posthospitalized mental patients?

Defining Treatable Patients

Restrictions from another side limit generalization in evaluative research. Any given treatment or service program assumes a part of the answer to the question of its own effectiveness by directing itself to predetermined categories of patients. Thus it says, in effect, we will (or can) work better with one type of client than with another.

The "community function" of the agency draws the broadest boundaries; for example, to

serve the aged, the adolescent, the tuberculous, or the ex-mental hospital patient. Within these boundaries further criteria of inclusion or exclusion are explicitly or implicitly accepted. Adjectives modify the clientele: healthy aged, female adolescents, arrested tuberculosis cases, or ex-hospitalized schizophrenic patients, are acceptable for treatment.

Still further exclusions are made by defining the type of services available; for example, healthy aged who need a home, adolescent girls who are going to have out-of-wedlock babies, arrested tuberculosis patients who can be expected to return to work or housekeeping, or ex-hospitalized schizophrenic patients who need rehabilitation.

Finally, among those potential clients for whom the services are intended, agencies develop conceptions of clients who can be best served by their skills. The rationale for these conceptions rests on estimates of competence in practice based on professional training and experience. It accepts, indeed, an evaluative conclusion before the question of evaluation is posed for research.

Thus the question asked of evaluative research might be restated as follows: How successful are we with those clients we want to serve and think we can help? This is an entirely legitimate question but it is much more restricted than the question: How effective is our program?

Research operations that come to grips with this restriction must seek explicit criteria to define the subject population from the viewpoint of the service agency. In the Altro project, staff and consultants formulated these general criteria: Bronx residents, 20-40 years of age, admitted only once to a mental hospital for 3-24 months, having formal psychiatric diagnosis of dementia praecox. In addition, to protect the going workshop program and in the interests of the patient, clinical criteria were to be applied in interviews by a psychiatrist to eliminate those who were "too sick" (revealing disturbing or dangerous psychotic symptoms, physically incapacitated, addicted to drugs), those who were "too well" (not in need of rehabilitation), and those having "alternative plans" (employment, household duties). Cases that survived all these criteria would be avail-

lows: Given matched groups of patients, will those who receive Altro services show greater progress, by some criterion of successful rehabilitation, than those who do not receive such services?

Altro planned to accept about 80 psychiatric patients during the 2 years of the study period. These patients would at any given time constitute about 20 percent of the normal caseload of approximately 200 patients at the workshop.

Defining Experimental and Control Groups

A service program, such as Altro's, is in general oriented to practice rather than to scientific research, and the canons of scientific methodology frequently appear to contradict the canons of practice. Altro's acceptance of a control-group design was therefore a bold step toward rigorous evaluation. As decisions were made to further this design, however, it was necessary to make some of the implications explicit.

With a control-group design one is in a position to say whether or not a program makes a difference to some population, on the basis of some criterion, such as return to the hospital. A program of rehabilitation includes many factors that might affect the client's welfare. The Altro program offers medical care, casework, vocational training, and other services as well as its distinctive workshop. Unless these factors can be specifically identified so that their counterparts can be examined in the experience of persons in the control group, our conclusion must be framed in general terms. We could say that Altro's patients in general fare better than non-Altro patients. From the standpoint of the community, this might be called the potential impact of Altro. It leads to statements about what the consequences would be if all patients were provided the same services as Altro's patients.

This kind of conclusion is very useful. It would require, however, further qualification in terms of the expressly defined population of patients to which it could be applied. If experimental and control groups were drawn from the population of all ex-hospitalized patients, our conclusion would mean one thing. If they were drawn from a population of patients limited by

interest in Altro, by stated characteristics, or by other definitions, our conclusion would thereby be restricted. This may be illustrated by considering a number of possible definitions of the subject population that might (ignoring practical considerations) be applied in this study.

Patients who were released from mental hospitals could respond in at least the following four ways to invitations to enter the Altro program:

1. They could be uninterested and decline the invitation.
2. They could be interested, explore the possibility, and decline to enter.
3. They could be interested, explore the possibility, enter, and withdraw at some stage in the program before it had been completed.
4. They could be interested, explore the possibility, enter, and graduate.

Furthermore, patients responding at any of these levels would constitute a population all of whom had had at least some information about Altro, ranging from mere knowledge of its existence to full participation in it. Therefore a no-contact category is logically required. Of such, at least two subcategories must be recognized since the distinction between them might be relevant to rehabilitation: (a) those ignorant of Altro altogether, and (b) those who know of Altro's existence but have had no further contact with it. Knowing about Altro could result in such meaningful reactions as: Is Altro the kind of place for people like me? Is it good or bad that people want to help former patients?

Similarly, each of the successive levels of contact noted above might reasonably be expected to have some effect on the patient's rehabilitation. Would the patient view an invitation to Altro as supportive or threatening? If a patient declined an invitation to Altro would he be punished or rewarded? And so on.

Generalization would be limited to that level selected as the population from which experimental and control groups were chosen at random. If a no-contact comparison group were used, statements about the impact of knowledge of Altro plus subsequent contact would be permissible. If the population were defined as patients informed about Altro but with various levels of contact with it, generalization would be appropriate only at the specified level. If

control samples from those patients who actually enter the workshop and who are therefore subject to the rehabilitation program, we could evaluate the program. Because this would require arbitrary denial of service to some of those who have already accepted it, such a design is difficult to execute even for the most willing operating agency. A more feasible alternative would be to require the agency to extend maximum effort to see that patients selected for the experimental group were brought into the program.

Defining Successful Rehabilitation

Whatever the experimental design, the definition of what constitutes successful treatment poses additional issues. These will not be considered in detail in this paper. Criteria for successful rehabilitation can range from "objective" measurements, such as permanent avoidance of readmission to a hospital, to clinical judgments about the level of mental health of the patients, with various indicators of adjustment in between.

Whatever criteria are used, the value of a study is enhanced if the experimental design requires impartial application of the criteria to experimental and control groups alike. It will not, to be sure, support general statements about effectiveness of a program unless a fairly inclusive range of criteria is offered. It is at this point that some theory of what the rehabilitation program is supposed to do for patients becomes indispensable. Theory about treatment of the mentally ill is in a state of flux today. Therefore evaluation studies should, in our opinion, always include indicators such as rate of readmission along with other criteria. Attention should be given as well to the duration of whatever effects are observed.

In the Altro study, hospital status 1 year after release is the primary criterion but, in addition, employment adjustment, presence and type of psychiatric care, and a judgment of the patient's current competence for managing are included in the followup interview. Brief before-and-after attitude tests have also been used.

Conclusion

If a research plan as promising as that reported here encounters such serious obstacles, is

it futile to attempt rigorous evaluative research that is so badly needed? We think not. Several kinds of contributions can be made, and their importance will be directly related to the rigor with which the evaluation was planned and executed.

In the first place, a description of the selective process is of crucial importance to the interpretation of evaluation studies, and this is seldom reported in the literature of mental health. Second, analysis of the results of well-designed evaluation studies, even when they fall short of full success, will contribute to an understanding of the service program with greater certainty and more appropriate caution. Furthermore, each carefully conceived effort to meet the requirements of valid evaluation will provide experience to enhance the next attempt.

We sought to make explicit some of the inherent requirements of evaluative research. The difficulties encountered in the Altro project should not discourage evaluative research; their identification is the first step toward overcoming them. But this report should encourage modesty in making claims for service programs in mental health. As more certain knowledge accumulates, we may expect these programs to become more firmly based and demonstrably more effective.

able to Altro and hence the subjects of the evaluative research.

A conflict between voluntary and authoritarian programs of treatment becomes pertinent at this point. Most private agencies, Altro included, adopt a treatment philosophy that expects the client to "accept" or "want" help in contrast to a treatment philosophy that asserts what the patient "should" or "must" do or have done to him. For example, State mental hospitals get "permission" to administer shock therapies; private agencies seek "cooperation" and "acceptance" of casework by their clients. Without prejudging the success of these approaches, we point out that the compromise of these conflicting philosophies of professional responsibility injects an additional selective definition of the subject population in evaluative research. We can describe some of the effects of this selective process on the Altro project.

Of the total caseload of ex-mental hospital patients at the Bronx after-care clinic, about 18 percent qualified under the general criteria enumerated above. Of these, about 28 percent survived the clinical screening, constituting only about 5 percent of the general population of posthospitalized mental patients. This is the point at which treatment and control groups were selected and evaluation could be said to apply only to these patients. Analysis of these groups, selected at random, indicates that the two samples do not differ significantly at the time of assignment with respect to any known characteristics.

The pool of patients from which both experimental and control groups were drawn does differ from the population of ex-hospitalized patients meeting the general criteria. The clinical screening process tended to anticipate the kind of clients the agency might favor. Specifically, the group of "available" patients includes a disproportionate number of single, white, better educated persons who have a higher occupational status, and who live with their parental families.

Because the selection just described occurs before experimental and comparison groups are chosen, it may be said to be controlled, if follow-up and before and after measurements are applied to these samples. However, it cannot be

assumed that the process of selective bias will cease at this point.

The professional approach of those providing service tends to select patients of unknown characteristics among those available to receive treatment. The logic of evaluative research would require, without compromise, that those designated for treatment be given treatment; the values of social casework and rehabilitative practice tend to assume that treatment should only be given to those who would accept it. Practitioners often argue that they can be effective only with such patients although this is one of the key questions that evaluative research is supposed to answer.

Of the pool of patients available as experimental cases for the Altro project, about a third had no contact whatsoever with Altro, another third had limited contact with members of the staff, and the final third actually entered the workshop. If the latter group is considered to be the only one composed of cases subject to the rehabilitation program, it constitutes a selected population for which the principles of selection might be explored retroactively. If the individuals in that group differ from the control group, the differences may be attributable to selection and not to treatment. Comparing patients (*a*) who received treatment, (*b*) who had lesser contact with Altro, and (*c*) who were offered services but received none with the control group can provide a picture of how this selective process operated. We can attempt to match each of these sets of experimental patients with patients in the control group. But the rigor of random matching cannot be claimed except to assess the effect of being offered the opportunity to enter Altro.

Inspection of the consequences of the selective process suggests that those patients reaching the rehabilitation program proper tend to be of two types: (*a*) those rather highly motivated to accept the kind of casework help and vocational training Altro offers, and (*b*) those who accepted Altro largely because they seemed unable to make any other sort of adjustment to the world outside of the hospital. Naturally enough, Altro is likely to feel that it is successful with the former and unsuccessful with the latter.

facilitates direct comparison (see figure).

When the test is finished, the trays are easily cleaned by flushing them under a tap, rinsing them in distilled water, and air drying.

One thousand specimens, formerly requiring 2,000 Kolmer test tubes, are now tested in 21 trays, each costing 47 cents. Each tray can be used at least 6 times, representing a cost of about 8 cents for 48 specimens.

Use of one tray is equivalent to the handling of 96 test tubes for refrigeration, incubation, and reading. In our laboratory, 500 complement fixation tests were performed by one technician utilizing the trays.

A tray, containing 48 specimens, can be read at a glance. The technician's hands are thus free while reading, enabling him to record results without clerical assistance.

Without sacrificing quantity, the

plastic tray technique permits use of one-half the quantity of reagent needed by the test tube method and effects a substantial reduction in the cost of personnel, refrigerator space, and cleaning facilities.

technique

Use of Plastic Trays in the CF Test

The bureau of laboratories of the New York City Department of Health has found that transparent plastic trays are a practical and reliable substitute for test tubes in the Kolmer complement fixation test.

The bureau explored the use of plastic trays in an attempt to reduce the costs of syphilis serology without diminishing the quality of its work. Experiments determined that the Kolmer complement fixation test performed in one-half quantity in the wells of the plastic trays matches the results of the test tube procedure.

In a comparative study, 578 serum specimens were tested simultaneously in plastic trays and in test tubes, each test in duplicate. The readings on the two sets of tests were in agreement on 551 of the serums and in disagreement on 27.

Readings in agreement on the duplicate tests performed by each of the two techniques were:

<i>Tube and tray tests</i>	<i>Serums</i>
R, R-----	369
R, WR-----	1
WR, WR-----	3
NR, NR-----	169
A/C, A/C-----	9

Total in agreement.... 551

Readings in disagreement on the duplicate tests performed by each of the two techniques were:

<i>Tube test</i>	<i>Tray test</i>	<i>Serums</i>
R, R-----	R, A/C-----	2
R, R-----	WR, WR-----	7
R, WR--	WR, WR-----	1
NR, NR--	WR, WR-----	6
NR, NR--	WR, NR-----	4
NR, NR--	NR, NR-----	1
R, R-----	NR, NR-----	1
WR, WR--	NR, NR-----	1
WR, NR--	NR, NR-----	2
R, R-----	A/C, A/C-----	1
NR, NR--	A/C, A/C-----	1

Total in disagreement.... 27

The degree of reactivity was determined according to the following scale:

Reactive (R)=10 to 100 percent complement fixation.

Weakly reactive (WR)=5 to 10 percent complement fixation.

Nonreactive (NR)=0 to 5 percent complement fixation.

A/C=test and control show equal or nearly equal inhibition of hemolysis.

In performing qualitative complement fixation tests in plastic trays, now routine in the bureau's syphilis serology laboratory, serum is put into the wells with a 0.2 ml. pipette,

and reagents prepared by Kolmer's procedure are added with automatic pipetting machines calibrated to deliver 0.25 ml. and 0.5 ml.

Reagents and serums are mixed by holding the tip of the pipette sufficiently high so that the force of ejection agitates the contents of the well.

After the trays are filled, they are stacked on top of one another, with sheets of cardboard in between, and refrigerated. The contents are given primary incubation by floating the trays on the surface of a 37° C. waterbath; reagents are added; trays are again placed in the waterbath and are then placed on a rack to be read.

The rack supports the tray about 3½ inches above a plate glass mirror reflecting the bottom of the tray to facilitate reading. A fluorescent bulb desk lamp, placed about 8 inches above the tray, shines directly through it.

Reading controls are prepared according to Kolmer's procedure. Reading standards are made by adding 1.5 ml. of 0, 5, and 10 percent standards to 75- by 12-mm. Kahn tubes. Serums with questionable reaction are transferred to Kahn tubes and compared directly with the standards. The comparator block

Site of enteritis epidemic in Shreveport, 1956

his house appeared green. An investigation was made, but the health department was not notified.

On August 11 a neighbor of Mr. X phoned the Caddo-Shreveport Health Department, stating that he, his wife, and his children were sick. He said there was a rumor that the water was bad. A sanitarian was immediately sent to the address to collect some water samples. The health department had no knowledge prior to this call of anything amiss with the city water supply. Because of the broken sewer line and the characteristics of the water, it was thought that sewage entering the bayou at this point was contaminating the water supply in the area.

On August 13, the water samples showed that heavy coliform contamination was entering the city water supply in the area where the com-

plainant lived. Eleven sanitarians went there immediately and began a search up and down the bayou for a possible cause of the bayou water entering the city supply. Within 2 hours they located Mr. X's pump in the bayou.

Some dye was put into the pump line to ascertain if the material would eventually reach the city main. The dye was detected shortly afterward in all the outlets in Mr. X's yard and in the city fire hydrant across the street.

As soon as there was proof of a direct connection between the bayou water and the city main, Mr. X was advised of the situation and asked to discontinue the use of the pump. He complied immediately.

The city water department severed the cross-connection and disconnected the water main from Mr. X's property. The contaminated line was flushed with clean water, and a heavy chlorine solution was allowed to remain in the line for a day or two. This procedure was repeated on several occasions, water samples being taken after each flushing. Beginning August 13, the sanitarians collected more than 300 water samples in the vicinity of the affected area and kept a continual surveillance of the water lines for chlorine residual. The people in the area were advised not to drink the water or else to boil it before use.

On August 14, health department nurses made a house-to-house canvass of the affected area for more epidemiological information. They found that approximately 70 persons had developed enteritis. The symptoms, similar in most cases, were nausea, vomiting, abdominal pains, tenesmus, and diarrhea, the latter bloody in some cases.

In laboratory examinations of stool specimens of some patients, *Salmonella infantis* was isolated from 1 specimen, *Salmonella panama* from 1, and *Giardia lamblia* from 2. *Salmonella oranienburg* was isolated from 1 water sample.

The local health officer and other physicians who attended patients made a diagnosis of dysentery on clinical evidence. Because of the danger of infectious hepatitis, gamma globulin was obtained from the Louisiana State Department of Health to administer to those who had been ill.

On August 23, none of the water samples

A broken sewer line and an improperly designed automatic lawn sprinkling system, which permitted bayou water to enter the city's main, led to 72 cases of enteritis in Shreveport, La.

An Epidemic of Enteritis Laid to Cross-Connection

FLOYD M. MILLER and
BEN FREEDMAN, M.D., M.P.H.

THE INCREASING use of water by a modern household for its many appliances increases public health hazards related to the water supply. The creation of more cross-connections, backflow connections, and open connections to accommodate these appliances and devices demands that sanitarians remain vigilant to prevent contamination of the water supply.

The misuse of one such device, an automatic lawn sprinkling system, led to contamination of the city water supply, resulting in an epidemic of enteritis in Shreveport, La.

In the summer of 1947, Mr. X installed a pump in Bayou Pierre, which flows behind his property, to supply water to the sprinkling system for the rear lawn of his home. His property is located in the southeastern area of Shreveport, the wealthiest residential section of the city.

In 1953 Mr. X installed for his front lawn an underground sprinkler system which drew its water from the city supply. This sprinkler system having been laid out in conformity with Shreveport's plumbing code, Mr. X applied to the city for a tap and meter for the system.

In June 1954, Mr. X installed an automatic time clock system and a booster pump in his

yard to use the bayou water for his w/s sprinkler system. At the same time, he replaced the pump in the bayou with another of horsepower capacity. He thought that the automatic timing system prevented a cross-connection. When the front sprinkler was connected to the bayou water system, the bayou water was not completely cut off from the city water main. Only a manually operated valve intervened between the city system and the bayou water system for the front lawn. This setup maintained a pressure in the sprinkler line of 65 pounds. Apparently, however, the pressure in the city water main at this point was at no time greater than 58 pounds.

Unfortunately, no inspection by the city plumbing inspector was requested. Mr. X's yardman, not knowing the hazard, opened the valves from the city water supply to prime the booster pump and left them open. Thus, when the time clock set the system into operation every 24 hours, water from both the bayou and the city main was forced through the system at the same time. Water from the bayou was probably forced into the city main for a fairly long period, since the two gate valves were found in the open position.

The Investigation

On August 7, 1956, a broken sewer line just off Bayou Pierre, about one-half mile from Mr. X's pump, was reported to the health department (see map). Investigation on August 8 revealed that the sewage from the broken line was draining into the bayou, and that the break had occurred about the beginning of August. Previously, the bayou water was fairly clear.

On August 8 the sewer break was corrected. The same day, the office of Shreveport's commissioner of public utilities received a call from a resident who said that the hydrant water in

Mr. Miller is chief sanitarian of the Caddo-Shreveport Health Unit and Dr. Freedman is director of the division of preventive medicine, Louisiana State Department of Health.

Site of enteritis epidemic in Shreveport, 1956

his house appeared green. An investigation was made, but the health department was not notified.

On August 11 a neighbor of Mr. X phoned the Caddo-Shreveport Health Department, stating that he, his wife, and his children were sick. He said there was a rumor that the water was bad. A sanitarian was immediately sent to the address to collect some water samples. The health department had no knowledge prior to this call of anything amiss with the city water supply. Because of the broken sewer line and the characteristics of the water, it was thought that sewage entering the bayou at this point was contaminating the water supply in the area.

On August 13, the water samples showed that heavy coliform contamination was entering the city water supply in the area where the com-

plainant lived. Eleven sanitarians went there immediately and began a search up and down the bayou for a possible cause of the bayou water entering the city supply. Within 2 hours they located Mr. X's pump in the bayou.

Some dye was put into the pump line to ascertain if the material would eventually reach the city main. The dye was detected shortly afterward in all the outlets in Mr. X's yard and in the city fire hydrant across the street.

As soon as there was proof of a direct connection between the bayou water and the city main, Mr. X was advised of the situation and asked to discontinue the use of the pump. He complied immediately.

The city water department severed the cross-connection and disconnected the water main from Mr. X's property. The contaminated line was flushed with clean water, and a heavy chlorine solution was allowed to remain in the line for a day or two. This procedure was repeated on several occasions, water samples being taken after each flushing. Beginning August 13, the sanitarians collected more than 300 water samples in the vicinity of the affected area and kept a continual surveillance of the water lines for chlorine residual. The people in the area were advised not to drink the water or else to boil it before use.

On August 14, health department nurses made a house-to-house canvass of the affected area for more epidemiological information. They found that approximately 70 persons had developed enteritis. The symptoms, similar in most cases, were nausea, vomiting, abdominal pains, tenesmus, and diarrhea, the latter bloody in some cases.

In laboratory examinations of stool specimens of some patients, *Salmonella infantis* was isolated from 1 specimen, *Salmonella panama* from 1, and *Giardia lamblia* from 2. *Salmonella oranienburg* was isolated from 1 water sample.

The local health officer and other physicians who attended patients made a diagnosis of dysentery on clinical evidence. Because of the danger of infectious hepatitis, gamma globulin was obtained from the Louisiana State Department of Health to administer to those who had been ill.

On August 23, none of the water samples

were positive. The water supply was officially declared safe for use 5 days later.

Analysis of Data

The data collected showed that 40 females and 32 males developed enteritis. Most of the cases occurred in children under 10 years of age, and in adults 35 years of age and over; only 2 were in infants. The total of 72 cases, none fatal, occurred in 27 households whose population was approximately 125. The attack rate, therefore, was about 60 percent.

Fifty-six of the cases occurred between August 9 and 13. This suggests that a common agent and a common set of circumstances acted over a short period of time.

The cross-connection between the lawn sprinkling system and the public water supply may be considered as the initiating factor of the epidemic because of these circumstances:

- 1. All the cases occurred in households supplied by the water main contaminated by the cross-connection on Mr. X's property.
- 2. The bayou water was heavily contaminated because of the sewer break near Mr. X's property.
- 3. The dye test showed that the bayou water was reaching the city main in a relatively short interval.
- 4. The water pressure in the sprinkling system was greater than in the public water supply.
- 5. The gate valves in the sprinkler system

Occurrence of cases of enteritis in relation to incubation period, sewer break, correction, and beginning of control measures, Shreveport, La., 1956

line were frozen open, allowing the bayou water to flow into the public system.

6. The sewer break was corrected on August 8, and 3 days later the number of cases began to decrease.

7. The last primary case occurred 3 days after the cross-connection was severed and the water supply received increased chlorination.

In the neighborhood where the epidemic occurred, 206 water samples were taken from 69 residences. More than one sample was taken from most households; 62 of the samples were positive, 144, negative.

These results indicate that the contaminated water supply was the offending agent: among households with no cases, twice as many had all negative samples (30) as had at least one positive sample (16); twice as many of the households with cases had at least one positive sample (15) as had all negative samples (8).

All 16 samples taken on August 11 and 13 were positive for coliform bacilli. After chlorination was begun and the cross-connection was severed, 1 sample in every 4 was positive. This ratio later decreased to 1 in every 5, and after August 23 no more positive samples showed up.

Considering that the first cases occurred August 5 and the last two on August 17, the outbreak was probably caused by a stepped-up contamination of the water system beginning when the sewer line was broken (see chart). Since the buildup of contamination in the bayou water took several days, heavy contamination conceivably did not reach the property of Mr. X until August 6 or 7. With 3 days incubation for the offending agent, heavy contamination should have been reflected in a peak of cases about August 9; the actual peak was August 9-11.

The precipitous decrease in the number of cases began 6 days after the sewer break was corrected. This decrease is expected if we accept the premise of the incubation period and of dilution lessening sewage contamination in the bayou.

The epidemic apparently began to subside because the sewer line was repaired. But straggling cases may have been prevented by the later control measures, whose effect should have

been manifest by August 16. On that date, no new cases occurred (see chart).

The case distribution among families seems to indicate that none of those occurring up to August 11, the last day of the epidemic's peak, were family contacts. Of the 24 subsequent cases, 13 could have stemmed from family contacts, including the last 2, occurring on August 17 in households where other persons had enteritis about a week earlier.

No definite bacterial agent was isolated in stool examinations. The sequence of events, however, does fit the theory of an agent with a 3-day incubation period. The illnesses could also have been caused by a filtrable virus.

We must consider the possibility that the epidemic was caused by sewage intoxication. If this was true, then the epidemic should have ceased several days after the control measures were taken on August 13. For all practical purposes this actually happened (see chart). The plausibility of intoxications is partly affirmed by the fact that no definitive causative bacterial agents were isolated from stool specimens, although a viral agent remains a possibility. But if intoxication was the cause, then the presumption of contact cases is invalid.

The specific offending agent of the epidemic remains unknown. A bacterial source is possible, but a viral agent, a sewage intoxicant, or a combination of offending agents is also plausible. That the vehicle of transmission of the offending agent was the bayou water is quite clear, and that the offending agent was associated with the sewer break is circumstantially evident.

If more information on water supply hazards had been exchanged between the local public utilities department and the health department, action to control the epidemic would probably have been quicker.

The Official Response

As a result of these events, the Shreveport City Council adopted an emergency ordinance requiring that all sprinkler systems be registered with the city plumbing inspector, and the plumbing board urged that the plumbing code be enforced to the letter.

Control of Silicosis in Vermont Granite Industry

PHS Publication No. 557. 1957. 65 pages. 40 cents.

Results of a study of the effectiveness of methods to prevent silicosis in the Vermont granite industry are described in this progress report. It traces early studies of silicosis in the industry and developments in engineering control of granite dust, describes the current silicosis control program, and presents findings of a re-study conducted in 1955 by the Public Health Service in cooperation with the Vermont Department of Health.

The report demonstrates that great strides can be made in national control of silicosis by properly applied medical and engineering measures.

Patients in Mental Institutions, 1955

Part I. Public Institutions for Mental Defectives and Epileptics

Part II. Public Hospitals for the Mentally Ill

Part III. Private Hospitals for the Mentally Ill and General Hospitals With Psychiatric Facilities

Part IV. Private Institutions for Mental Defectives and Epileptics

PHS Publication No. 574. 1958. Part I, 55 pages. Part II, 72 pages. Part III, 41 pages. Part IV, 26 pages.

Based on the 30th Annual Census of Patients in Mental Institutions, the ninth to be conducted by the National Institute of Mental Health, these publications present basic statistical data on the movement of the patient population of mental institutions in each State and in the United States.

The public institution and public hospital reports, parts I and II, con-

tain detailed tables on first admissions, resident patients, personnel employed, and expenditures for the care of patients. Parts III and IV carry data on the characteristics of first admissions to private mental hospitals and to private institutions for mental defectives. Statistics on the characteristics of discharges from general hospitals with psychiatric facilities are also included in part III.

Public Participation in Medical Screening Programs

A Sociopsychological Study

PHS Publication No. 572. 1958. By Godfrey M. Hochbaum. 23 pages; tables and charts. 15 cents.

Results of an intensive behavioral research study on determinants of voluntary participation in free medical screening programs are reported in this monograph. Although tuberculosis case-finding programs were used as source material for the study, the methodology and findings can be applied to screening activities in other disease detection programs. The findings relate to such factors as information, fear, socioeconomic level, and social forces. The study was sponsored by the National Tuberculosis Association and the Public Health Service.

Education, Training, and Utilization of Sanitary Engineers

National Academy of Sciences, National Research Council Publication. 1957. 17 pages.

Findings and recommendations of the Conference on Education, Training, and Utilization of Sanitary Engineers are summarized under three headings: career opportunities,

recruitment and recruitment incentives, and educational objectives.

The conference was held under the auspices of the Subcommittee on Personnel and Training of the Committee on Sanitary Engineering and Environment of the National Academy of Sciences, National Research Council in Washington, D. C., March 1957.

Copies of the report can be obtained from the Division of Sanitary Engineering Services, Attention: Engineering Resources Program, Public Health Service, Washington 25, D. C.

Births and Neonatal Deaths By Birth Weight: Reporting Areas, 1952-54

Vital Statistics—Special Reports. Selected Studies. Vol. 47, No. 1, Dec. 16, 1957. 19 pages; tables.

This is the second in a series of reports compiling comparative statistics on neonatal mortality by birth weight for States and cities. Vital records for 1952-54 served as a basis for the data, with information on mortality by birth weight obtained from certificates for matched births and neonatal deaths.

Distributions of births by weight and weight-specific neonatal mortality rates for white and nonwhite infants, as well as summary figures for prematures, are included in the data

Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

This comprehensive account of the growing challenge of transportation hazards to health and safety strongly emphasizes the responsibility of both physician and public health officer in preventing accidental trauma.

Health and Safety in Transportation

ROSS A. McFARLAND, Ph.D.

THE ASSURANCE of health and safety in transportation has become one of the basic needs in modern life. In certain areas of the world, safety in transit is assuming even greater importance than problems relating to food, shelter, and clothing. In the United States, for example, extensive mechanization of the environment, diverse industrial procedures, and increasing use of transport vehicles have resulted in new threats to the well-being of large sections of the population.

The important role played by human variables in causing accidents brings the control of accidents within the province of preventive medicine and public health. The physician and the public health officer, with their broad training in the biological sciences, are especially qualified to improve safety in industry, in the home, and in various forms of transportation.

Efforts in the control of accidents can be

Dr. McFarland, who is professor of environmental health and safety at the Harvard School of Public Health and director of the Guggenheim Center for Aviation Health and Safety, is a prolific author on the subject of transportation safety. The paper was delivered in essentially the same form before the American College of Preventive Medicine in Cleveland, Ohio, on November 13, 1957. Many of the studies reported were sponsored by the Commission on Accidental Trauma of the Armed Forces Epidemiological Board, Department of Defense, and supported in part by funds from the Office of the Surgeon General, Department of the Army.

strengthened by the application of epidemiological techniques. The methods which have been used so effectively in the control of infectious disease can be broadened to prevent injuries, especially on the highway and in the air (1). Since most accidents have multiple causes, the interactions between the "host" (driver, pilot, or operator), the "agent" (vehicle, plane, and equipment), and the "environment" are important considerations in attempts at control. While the host factors are of particular interest to physicians, they must be viewed in their relationships to the agent and the environment for an adequate understanding of accident causation (2).

Because human variables are especially important in causing accidents, the physician or the public health officer has a direct responsibility in the prevention of injury. Moreover, since memory operates most effectively when reinforced by emotion, the physician is in an especially favorable position to teach while treating and to indoctrinate patients with the principles of accident prevention. It is thus of great importance for the physician to take the initiative in identifying the causes of accidents in order to institute preventive procedures (3).

Current approaches to the control of accidents may possibly be reaching the limits of their effectiveness. The next significant advances in safety may result from a combined approach which includes the engineering and

biological sciences. This collaboration is not new in medicine, and such an approach has been the basis of many important developments. For example, the control of malaria was achieved by cooperation between the entomologist, the sanitary engineer, and other specialists. The physiologist, the psychologist, the anthropologist, the engineer, and the physician can similarly cooperate to obtain basic data in order to achieve improved prevention of motor vehicle accidents (4).

Transportation Facts and Figures

A few examples of the extent to which passenger transportation has increased in modern times show the magnitude of the problem.

In 1956, buses, automobiles, taxis, and trucks, operated by 77 million licensed drivers, traveled some 630 billion miles on the highways in the United States. Drivers and passengers in automobiles and taxis alone accounted for 970 billion passenger-miles of travel; 51½ billion passenger-miles were recorded in intercity bus operations.

In aviation the volume and speed of travel have been increasing very rapidly. During the first 24 years of the air transportation industry, that is, up to 1950, 100 million revenue passengers were carried by scheduled domestic and international carriers in the United States. By 1957, 349 million revenue passengers had been carried. The number of revenue passengers on airlines of the United States in 1956 was about 46 million. These represented about 70 percent of the total world volume of 68 million revenue passengers on airlines. In 1956 for the first time more passengers were carried to Europe by air than by ocean liner, and 68 percent of all passenger traffic between the United States and other nations was by air. Helicopter scheduled airlines were nonexistent 5 years ago. In 1957, this new type of service carried 152,000 passengers (5, 6).

The transition from piston engines to jet propulsion will impose new and interesting problems in the next few years. Approximately 350 jet transports are now on order. These planes will carry as many as 140 passengers each at a cruising speed of approximately 600 miles per hour.

The number of revenue passengers using the railways exceeds 400 million per year, excluding commuters. Also, in 1956, more than 9 billion separate fares were paid by local transit riders.

It is now apparent that almost everyone uses some mode of travel or another, not once, but many times during the course of the year. The exposure of our populations to travel hazards has reached enormous proportions both in relation to accidental injury and the threat of exposure to certain diseases.

The frequency of accidents now presents a major problem. Each year approximately 95,000 persons are killed in various kinds of accidents in the United States (fig. 1). About 350,000 others receive permanently disabling injuries, and temporary disabilities severe enough to keep them away from work for at least a day are incurred by 91½ million persons. These accidents occur mainly in the home, on the job, and during transit. Accidents in various forms of transportation, particularly on the highway, have reached epidemic proportions. Since the invention of the automobile there have been more than a million fatalities in motor vehicle accidents in the United States; in 1957, highway accidents accounted for 41 percent of all accidental deaths. The annual direct costs of traffic accidents approximate 2 percent of the national income (7, 8).

Fatal accidents involving persons under 35 years of age formed a large proportion of the

Figure 1. Accidental deaths in the United States during 1955.

SOURCE: Reference 7.

total deaths in highway accidents. This implies an enormous drain on the productive resources of the country. Accidents are the leading cause of death for persons between 1 and 34. They are exceeded only by heart disease and cancer for those between 35 and 44 years of age (9).

In the armed services, accidental trauma is now a major problem. During World War II the United States Army reported more deaths among its soldiers caused by accidents than by disease for the first time in its history. In the Korean conflict more than half of the hospitalized casualties resulted from accidents rather than from enemy action. Of these, 70 percent were incurred in motor vehicle accidents (1). The frequency of motor vehicle accidents in all three branches of the Armed Forces has become very serious, and accidents now exceed upper respiratory infections and rank first as the leading cause of man-days lost. Motor vehicle accidents account for about 2,100 fatalities of servicemen each year, a large majority occurring while personnel are off duty (10).

The integration of motor vehicles into our way of life has become very costly in fatalities, injuries, and damaged equipment. In spite of the enormous increase in volume of highway traffic, there has been a significant decrease in accident rates during the past 25 years. For example, in 1957 the fatality rate per 100 million miles of travel was only 5.9, in comparison with the rate of approximately 15 about 20 years ago. Nevertheless, the actual number of persons killed or disabled and resulting costs to the Nation's economy have increased from year to year with only a few exceptions apart from the period of restricted travel during World War II. In 1957 there were approximately 38,500 deaths and 1,350,000 injuries disabling beyond the day of the accident (7). According to present trends, it is estimated that 1 of every 10 persons in the country will be injured or killed in a traffic accident during the next 15 years (8).

The safety record of scheduled airlines in the United States is an enviable one in relation to the exposure. Only 154 fatalities were reported for 1956, with the 128 deaths in the Grand Canyon accident accounting for approximately five-sixths of this total (5). In 1957,

there were 31 deaths. Business flying is reasonably safe, but private flying has a relatively poor record. There were 655 fatalities in 1956 in 3,411 accidents among 65,000 business and private planes. Thus, 1 in about every 19 of these airplanes was involved in an accident. Crop dusting by airplanes, of great importance to both public health and agriculture, is also hazardous. Military flying obviously involves increased hazards. However, in United States naval aviation there is now only about one fatality per day. For example, in 1956, there were 413 deaths attributable to aviation accidents (11). In the U. S. Air Force, with its far more extensive operations, deaths have been reduced to about three per flying day (12). In 1955, there were 825 fatalities.

To determine precisely the relative safety of different kinds of transportation is impossible because of the lack of a satisfactory common denominator for a valid comparison. The nature and frequency of the hazards encountered differ greatly among the various forms of transport, as does the number of passengers exposed to danger of injury in the different types of vehicles (13).

At present, death and injury rates per 100 million passenger-miles are used in estimating the safety of travel, and, on this basis, table 1 shows the accident death rates in passenger transportation (5, 7). While deaths per 100 million passenger-miles is not a wholly satisfactory basis for this comparison, it appears that on the whole buses and trains have the lowest rates. Those for automobiles and taxis are much higher, and air transportation occupies a

Table 1. Accidental deaths of passengers per 100 million passenger-miles in United States transportation, 1947-56

middle position, slightly above those for trains and buses. Actually, the accident frequency rates for air transportation are quite low; the fatality rates reflect chiefly the fact that there are few survivors in the major accidents.

Epidemiological Approach

A basic step in the application of the epidemiological approach is determining the fundamental physical, physiological, and psychological characteristics of the host. When these data are correlated with the characteristics of the agent (vehicles and equipment) under specific environmental conditions, the resulting information will shed light on the causes of accidents and aid in developing preventive measures. To obtain this kind of information experimental and clinical studies, epidemiological surveys, and careful statistical analysis are required (3).

An epidemiological approach to highway safety in the armed services was applied in a recent study sponsored by the Commission on Accidental Trauma of the Armed Forces Epidemiological Board. About 88 percent of highway accidents in the Navy and Marine Corps occur while the personnel are off duty. The epidemiological method was used to study this problem at a major Marine Corps base.

It was previously supposed that the main problem concerned fatal accidents during weekend periods on considerably long automobile trips. The study showed, however, that 96 percent of the accidents occurred within a 50-mile radius of the base, and 71 percent within 10 miles. The greatest percentage of accidents occurred between 6 p.m. and midnight, that is, during the evening recreation period. The analysis identified the young, unmarried enlisted men of low rank who live on the base in Government quarters as having a highly disproportionate share of the accidents. These findings have formed the basis for a new accident control program at this military installation (10).

It will not be possible to present a complete analysis of the epidemiological approach in both the highway and air transport fields, and primary emphasis will be given to the findings relating to highway safety. However, there are

several interesting problems in the field of air transportation which have far-reaching implications for the health and safety of large sections of the population, and a few of these will be singled out for special mention. The first one concerns the medical care of the flight crews and the handling of problem medical cases. This will be considered in the discussion of host factors. The second refers to the possibility of spreading disease by aircraft, which will be treated under the heading of host-agent factors in health and safety. The third involves host-environment relationships in connection with the transportation of patients by air, and the problems which may arise from a loss of pressure in pressurized air transports.

Host Factors in Accidents

Thus far no single characteristic of drivers has been identified which accounts for a large proportion of accidents on the highway. This is true for a variety of sensory, psychomotor, and psychological investigations (8, 14). A few useful generalizations may be made, however, about driver characteristics in relation to accidents.

Results of a number of studies clearly indicate that, in relation to their numbers, drivers up to the age of about 25 have accidents more frequently than do those from 30 through 60 or 65 years of age. The most recent and complete information, from Massachusetts and Connecticut, indicates the highest rates for the

youngest drivers, those of age 16. The rate decreases with succeeding years of age, rapidly at first and then more slowly (fig. 2). It levels off at about age 30 and remains stable and relatively low through age 65 (15, 16). Data related to ages above 65 are as yet too meager for interpretation. The factors responsible for the higher rates for youthful drivers are believed related to inexperience and to psychological characteristics of youth in the adolescent and early adult phases of adjustment (8).

In the United States, roughly 10,000, or about half, of the high schools in the country offer classroom instruction in highway safety and training in the operation of automobiles. A number of studies have been made on the effectiveness of this training. The results, shown in figure 3, agree substantially that the accident rates of trained drivers are about half as high as those of untrained, at least during the first few years of driving (17). Many of the reports also indicate fewer violations of traffic regulations by trained drivers. It is also apparent that classroom instruction alone is less effective than a combination of classroom instruction and behind-the-wheel training. It thus appears that the adequate initial training of drivers constitutes an important method of reducing accidents in a portion of the driving population presently characterized by the highest rates. There is still the need, however, for research on what should be taught, on ways

to provide training in driving under adverse conditions and in the handling of emergency situations, and on ways to expand training programs to include all beginning drivers (8).

Of the greatest importance in driving safety are the attitudes and personal adjustments of drivers. A useful concept which has been developed in this area is that "a man drives as he lives." Studies of accident repeaters and accident-free drivers carried out in Canada showed that maladjustments in meeting the personal and social demands of living were far more frequent among the accident repeaters than among accident-free groups. A promising method for the identification of accident-repeater drivers resulted from this study (18). It was found that, as a group, the accident repeaters could be differentiated from the accident-free drivers on the basis of the number of contacts with such agencies as the civil and criminal courts, collection agencies, public health clinics, and social welfare agencies (fig. 4).

The same procedure was subsequently ap-

Figure 4. Personal and social adjustments of accident repeaters and accident-free drivers matched for geographic location and driving experience.

SOURCE: Reference 18.

plied to a large sample of truck drivers in a study at Harvard. Accident-repeater and accident-free drivers were carefully matched to meet rigid standards, and various public records were searched for their names. Findings very similar to those in the Canadian study were obtained. A statistical analysis by the chi-square technique was made to determine the relative usefulness of the various indexes of antisocial or maladjustment tendencies in differentiating those with repeated accidents from those without accidents. The relative value of selected items in discriminating between accident-free and accident-repeater drivers has been developed in the following manner:

<i>Item</i>	<i>Chi-square</i>
Court record of automobile offenses.....	7.48
Minor violation in motor vehicle records.....	6.76
Court record of offenses against persons.....	6.43
Unfavorable business inspection report.....	3.84
Court record of offenses against self.....	2.55
Court record of offenses against property.....	2.01

The values for the individual items having greatest significance were applied as weights to the information obtained on a new sample of unselected drivers. In this preliminary experiment the procedure identified the accident repeaters in the sample with an accuracy of 85 percent (19).

In another study information from the service records of 210 military pilots who had been killed in noncombat aircraft accidents was compared with records of a 20 percent sample of reserve pilots discharged after satisfactory service (personal communication). A record of disciplinary charges was found for 48 percent of the fatal accident group as against 31 percent of the control group. "Violation of flying orders" was the most discriminative type of offense—21 percent of the fatal accident group as against only 2 percent of the controls. Nonflying disciplinary infractions were also significantly different in the two groups, the accident group rating higher in resistance to order and discipline. Also noted in the accident group were the larger proportion of pilots who had not completed high school and the larger proportion of pilots who changed jobs frequently prior to enlistment.

An intensive investigation of personality factors in relation to accidents is currently being

made at the University of Colorado. This approach includes extensive psychological testing and intensive psychiatric evaluation. One group test—a modified form of the Allport-Vernon Scale of Values—has provided a 70 percent accurate discrimination between no-accident drivers and those with a high-accident record. Characteristically, and in contrast with the accident-free, those drivers who have had accidents scored high on the theoretical and aesthetic scales and low on religious values. Through a combination of the test results and the clinical material, it appears that the accident-prone driver is less likely to identify himself with the father, more likely to consider authority figures unpleasant, and more likely to show an excess of regressive, masochistic fantasy. The most useful tests are now being given to all of the high school students in the city of Denver. The results will be correlated with their subsequent driving records (10).

In situations involving time stress and complex reactions, the lower accident-rate for adult and middle-aged drivers is clear, but for persons past middle age there is some evidence that the rate may increase. It is known that reaction times tend to become longer with advancing age, and impairment in the efficiency of all the senses occurs. Many persons, however, develop compensating habits offsetting these losses. It is believed, for example, that older drivers tend to drive slower and to do less driving at night.

Research carried out at Cambridge University on the effects of aging on skilled performances has suggested the kinds of situations in which aging persons might be especially vulnerable to accidents. The implication is that when an older driver is required to assimilate a novel or complex situation instantaneously, and to carry out a rapid sequence of reactions, he is apt to become confused and make errors. Without time pressure and in familiar situations, a more adequate or efficient response can be expected (13, 20).

Many accidents occur when the efficiency of the driver is impaired by some temporary condition. The efficiency and safety of driving may be adversely influenced by a variety of temporary states, although, in general, statistical

proof of the importance of a given type of condition may be very difficult to obtain. For example, the role of fatigue in asleep-at-the-wheel accidents appears quite clear, but fatigue may be a more subtle factor in many other accidents. When drivers are emotionally upset or preoccupied with personal problems, alertness to the driving situation may be diminished. Alcohol is widely cited as a cause of accidents. And what may be the influence of concurrent disease or of various abnormal physical conditions? Also, is safety compromised as a result of either the direct or side effects of various drugs and remedies taken for a variety of medicinal purposes (8, 14)? The following are several of the findings concerning the influence of temporary conditions.

Driver fatigue is not only related to the length of time spent in driving. Consideration also must be given to such factors as amount and quality of previous rest, the nature of activities prior to driving, and concurrent emotional stress. In addition to the subtle disorganization of skill which develops with increasing fatigue, drivers when extremely tired may experience hallucinations of obstacles on the highway, and a number of accidents have been traced to actions taken by drivers to avoid collision with these imagined barriers. When interviewed confidentially, more than half of a sample of professional drivers engaged in long-trip driving admitted having had such experiences (19).

Driving skill is adversely influenced in many with as little alcohol in the blood as 0.03 and 0.04 percent. The likelihood of an accident increases constantly as the alcohol in the blood increases from the lowest levels (8, 14). The risk at 0.10 percent is estimated to be more than twice that at 0.05 percent, while the risk at 0.15 percent appears about tenfold (table 2). These data are from a recent study in Canada (21). Additional data from the same study (22) show that as the level of blood alcohol increases, there is an increase in driving errors which result in accidents. In several series of autopsies recently made on drivers killed in accidents in the United States, significant amounts of alcohol were found in the blood and brain fluids of more than half of the cases.

A physiological fact which may have special

importance is that, while initially there is a close correspondence between the levels of blood alcohol and brain alcohol, the alcohol is eliminated more slowly from the fluids surrounding the brain than from the blood. Thus, elevated concentrations of alcohol may be found in the spinal fluid for some time after blood values have become negligible (13).

Through control of problem medical cases preventive medicine has an important role in reducing accidents on the highway and in the air. The questions of physical fitness to drive and the influence of pathological processes in accidents are of particular interest to physicians.

Most authorities would agree that epileptics, diabetics requiring insulin, and those with certain heart conditions should not operate public highway conveyances or pilot airliners because of the hazard of a sudden loss of consciousness. But what of the influence of such conditions in the general driving public and what cutoff points should be kept in mind? There are, for example, about 6 million truck drivers in the United States, yet it is known that only a small proportion of them receive thorough physical examinations, and that the development of adequate medical programs for the large number of workers in the transport industry remains to be accomplished. It would be expected that in this occupational group, a certain number use insulin, experience temporary impairments of consciousness, or have fairly advanced heart disease of one form or another (8, 19).

In the interest of prevention, does not the

physician have a responsibility to indoctrinate the patient and the public regarding the influence of disease on driving and the effects on human behavior and efficiency of prescriptions and medications employed? Within the patient-physician relationship, must not the cardiologist, for example, estimate the likelihood of sudden loss of consciousness in various forms of heart disease and advise his patients whether it is safe to drive? In this connection, what advice should the physician give his diabetic patient? Or how is safety compromised when with advancing age changes in sensory functions and reaction time can no longer be compensated by training and experience? How can the patient-physician relationship be reconciled with the physician's responsibility for the prevention of injury when there is a question of public safety?

Unfortunately, there are few controlled experimental data available to determine precisely the role of various clinical conditions in highway safety, or to establish medical criteria and cutoff points concerning fitness to drive. Conditions involving a sudden loss of consciousness provide the most dramatic illustrations of the influence of disease in accidents. For example, in England the incidence of coronary thrombosis over a 5-year period was studied among the bus drivers of the London Transport Executive. There were 133 cases. Six prompt fatalities occurred while the driver was at the controls of a bus. Three of these resulted in accidents. In the other three attacks, the operator was able to stop the vehicle without harm (23).

The need for research to evaluate the influence of specific conditions in traffic accidents and to establish critical cutoff points is very great, and physicians obviously can make important contributions in this regard. The limitation on driving for persons with various illnesses or disabilities presents a serious problem. The American public, moreover, does not readily accept limitations on personal freedom. An arbitrary prohibition of driving for all those afflicted with certain conditions would be needlessly restrictive and unfair to many persons, and cooperation between the medical profession and the motor vehicle authorities in handling these problems on an individual basis is essential. Several studies have shown that

drivers with quite severe physical limitations may have safe records if they are carefully supervised by their physicians. In Massachusetts, for example, a satisfactory safety record has been found with certain high-risk drivers permitted to hold licenses and drive under a program of continuing medical surveillance. These drivers include persons with such disabilities as epilepsy, diabetes, multiple sclerosis, and various amputations and paralyses (8).

If the problem of medical fitness to drive is to be satisfactorily worked out, large-scale studies of persons with various disabilities must be carried out to let them help decide which of this group should not drive. For example, a physiological and clinical study of 1,000 diabetics, together with statements from them about critical incidents and episodes and how they have been influenced in a dangerous way, would supply needed information in this area. Such a study might prove a more acceptable approach than the setting of arbitrary cutoff points without an experimental basis. A study of this type is at present being carried out at the Harvard School of Public Health.

In the field of air transportation, airline pilots receive periodic physical examinations through designated medical examiners of the Civil Aeronautics Administration. A few of the 80 airlines of the world have good medical departments, but less than one-fifth of the scheduled airlines have formal medical organizations. The report that each month, for a 5-month period in 1957, a pilot on active duty died while in the cockpit will emphasize the importance of continuing medical supervision, as well as of the value of having a co-pilot. One of the pressing problems in this area relates to the changing age distribution of airline pilots. With many of these men now entering age groups beyond 45 and 50, many problems of health and safety may be anticipated (24).

The findings for 232 problem medical cases among transport pilots have been followed through a period of 20 years. Permanent grounding resulted in only 83 cases, all of the others having returned to duty (13). The majority of cases were classified as neuropsychiatric and cardiovascular. Such studies are of great value in the delineation of cutoff points

for airline pilots, and, furthermore, they do not support the belief held by many pilots that a serious illness necessarily results in permanent grounding.

Host-Agent Relationships

A number of findings concerning transport health and safety relate to interactions between the host and agent. In the vehicular field host-agent relationships are primarily concerned with the effective integration of the man-machine combination. In order to promote that integration, automotive equipment should be designed with regard to human capacities and limitations.

Mechanical design should be intimately related to the biological and psychological characteristics of the driver. It is reasonable to expect, therefore, that machines should be designed from the man outward, with instruments and controls considered as extensions of his nervous system and appendages. This implies that the automobile should be built around the operator, with due regard for his requirements and capacities. When this is done there should be fewer accidents and no extensive redesigning of equipment after it is put into use (25), but until this is done, it is hardly fair to attribute so many accidents to human failures.

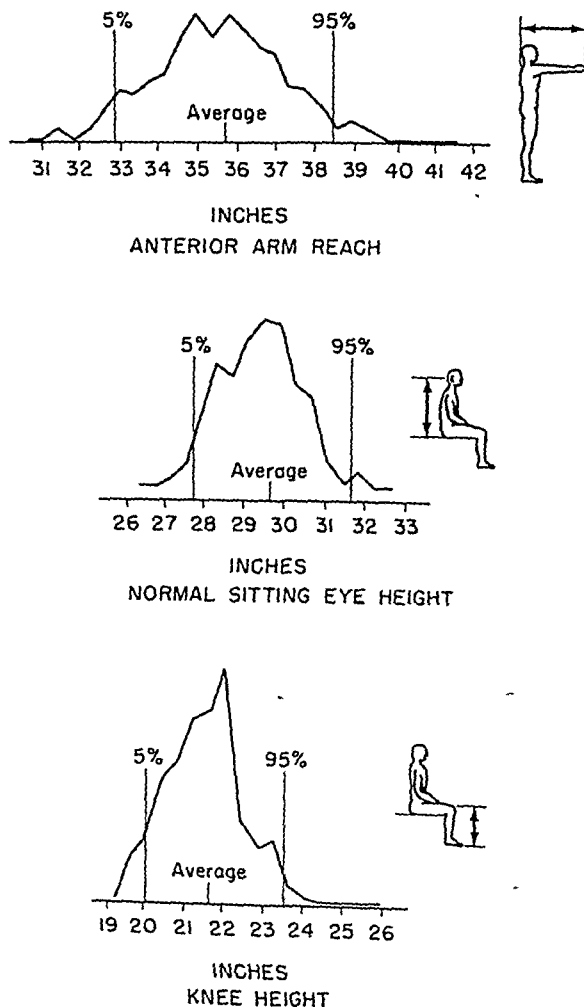

In general, any control lever that is unnecessarily difficult to reach and operate, any instrument that is difficult to read, any seat that induces poor posture or discomfort, or any unnecessary obstruction to vision may contribute directly to an accident. In addition, the cumulative effects of such difficulties lead to fatigue, to the deterioration of driver efficiency, and perhaps, eventually, to an accident (25, 26).

Numerous examples of faulty design in modern vehicles may be found from the standpoint of the range in body size of the drivers, the biomechanics of human movements and postures, and the characteristics and limits of human perception. A few examples are taken from a study at Harvard in which a number of current-model trucks were evaluated (19, 27). A common defect was insufficient range of adjustability in the seat, either horizontally or vertically. Again, important controls were often placed too far away. For example, in

one model only 5 percent of the drivers could reach and operate the handbrake from the normal driving position.

Clearances were frequently inadequate; in one model only the shortest 40 percent of drivers could get the knee under the steering wheel when raising the foot to the brake pedal. In another, this clearance was so small and the gear shift was so close to the steering wheel that the tallest 15 percent of drivers could not raise the foot to the brake pedal, by angling the knee out to the side of the wheel, without first shifting the gear lever away to the right. Figure 5 shows the distribution among truck and

Figure 5. Variations among approximately 400 truck and bus drivers in body-size dimensions important in driving.

Source: Reference 28.

bus drivers of three body dimensions important in driving, to illustrate the kind of information that may be used in designing to "fit" the drivers (28).

Inadequate vision from motor vehicles constituted a common problem, especially for the perception to the side and to the rear. Within the car or truck, instruments were frequently designed or placed so that they could not be read accurately and rapidly. Knobs and switches were sometimes identical in design and could not be distinguished from each other readily. Often they were so located that they could be operated inadvertently or by mistake. For example, a driver of one make of automobile had a serious accident while traveling at high speed during the night when he inadvertently shut off his headlights with the belief that he was pushing the knob for the cigarette lighter. Many examples illustrating such errors in design are found in the reports from studies carried out by the Harvard School of Public Health (19, 27, 28).

Baker and Grether (29) have demonstrated visually the principle of designing dials so that they can be read accurately and rapidly. Shown are 3 dials, 2 of which require the operator to interpolate between numbers on the scale. The third gives the necessary functional information at a glance.

Examples of the way in which knobs and handles can be shape coded to prevent the inadvertent operation of controls through mistaken identity have been developed by Jenkins and Sleight (30). Accurate visual discrimina-

Touch

Visual

tion can also be made when there is good color or contrast with the background.

Certain design features are especially important as causes of injuries to drivers and passengers in crashes. It is recognized that the crash and impact forces of a large proportion of fatal automobile accidents were actually within the body's physiological limits of survival, if the momentum of the body had been properly checked and the forces dissipated. A large-scale study of injury in relation to the structural features of cars and the circumstances is now based on the analysis of 8,000 cases per year (10). This study was initiated at the Cornell Medical College by the Commission on Accidental Trauma and has received substantial additional grants from two of the major automobile manufacturers.

An early finding in this study was that being ejected from the car considerably increases the possibility of injury or death. It was estimated that a reduction of 5,000 fatalities in the United States could be achieved each year by such means as improved door latches and the use of safety belts. Based on analyses of injuries sustained by 3,450 persons in 2,000 accidents, certain structures have been incriminated as important sources of injury to vehicle occupants. In addition to door latches that open and permit ejection, they are in descending order: the steering wheel and column, the instrument panel, windshield, top edge of front-seat back, door structures, and the lower part of the back of the front seat.

Another analysis in the Cornell study indicated that speed, when lower than 50 mph, is only partially correlated with the severity of injury. At the lower speeds especially, the design features in the car and the factor of ejection are of greater importance than the rate of travel at the time of the accident.

Transportation of Diseases

Another aspect of host-agent relationships is the spread of disease by various forms of transportation. Public health authorities recognize that certain diseases can be spread just as rapidly as the fastest means of transportation. However, many of the immigration, quarantine, and health regulations were adopted in reference to surface travel, and need

to be revised to keep pace with the modern airplane and the rapid transportation of persons from one part of the world to another (1).

The important implication of the speed of transit is that passengers can be conveyed from an infected to a noninfected area in less time than the incubation period of a disease, particularly by air transportation. Thus, infected travelers may directly expose other passengers and other persons prior to showing overt symptoms of disease, or bring a disease into an area which is free of the disease but contains a suitable vector. Also, there may be delay in proper treatment and appropriate preventive measures when the illness does become manifest because physicians in an area where it is not endemic may be unfamiliar with it (13).

There is also the possibility that insect vectors of disease may be carried to a noninfested area by aircraft. These insects may be merely transported and may spread disease by biting passengers during the flight. Or, escaping from aircraft after landing, they may become implanted in an area and produce new generations, creating a reservoir of infection. The possibility of transporting plant and animal diseases presents another important problem, held by some to be more serious than the threat to humans (31).

It had been predicted that diseases would be spread more easily with the advent of air transportation on a global basis. Thus far, however, there have been no major epidemics attributable to aviation. Contrary to the general impression, the epidemic of malaria in Natal, Brazil, in 1930 which later resulted in 100,000 cases was not introduced by aircraft. An evaluation of the time factors and the location of the original breeding sites at Natal in relation to the harbor and the airport led Soper to conclude that *Anopheles gambiae* was introduced, not by aircraft, but by the French destroyer making the mail run from Africa to Natal. Transportation by boat was also involved in the local epidemic of smallpox in the vicinity of Seattle in 1946 when a soldier returning from Japan came down with the disease while enroute and was hospitalized in that area (13).

Authenticated instances of the spread of disease through air transportation follow.

Toward the end of World War II, several

cases of smallpox were traced directly to a wounded soldier who arrived in San Francisco on a medical evacuation plane from Korea. He had apparently contracted the disease before enplaning and symptoms were not apparent on his arrival. Subsequently, approximately 100 cases developed in other parts of the west coast.

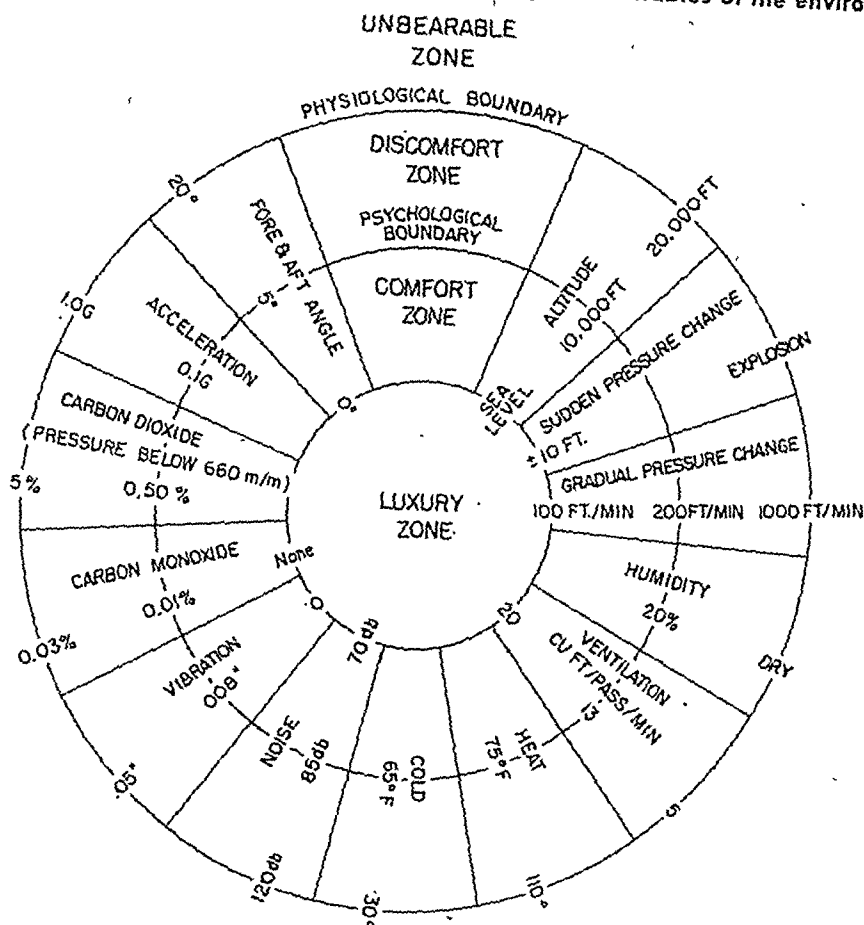

The so-called Arras epidemic of smallpox in 1946 in France was also traced to a soldier traveling by air. He had been stationed in Morocco and became ill during a flight to Italy, but he continued his journey to his home in Arras. He was not seen by a physician until 4 days had passed and was sent to a hospital with a diagnosis of chickenpox. Three days later the case was recognized to be smallpox, and in spite of revaccination of all known contacts a small epidemic followed, resulting in at least 1 death.

Another illustration concerns an outbreak of dengue fever in the Waikiki district of Honolulu in 1943. Several transport fliers arriving from the South Pacific had occupied an apartment in a Waikiki roominghouse. They had come through Suva in the Fiji Islands during an epidemic of dengue fever. Subsequently, the maids at this roominghouse became ill, and within a few weeks the Waikiki district became such a focus of infection that it was closed to military personnel until steps had been taken to virtually eliminate *Aedes* from the area.

An illustration of a potential epidemic is afforded by the case of a flight engineer who arrived in the eastern part of the United States 8 or 9 days after leaving a malarial area in Asia. He became ill shortly after arrival and was attended by a private physician who failed to recognize the disease, perhaps because of unfamiliarity with malaria. Two days later the airline's medical officer learned of the illness and had the patient hospitalized. Positive malarial smears were obtained, and despite intensive medical efforts the patient died from an overwhelming parasitemia of falciparum malaria approximately 13 or 14 days after infection. One may wonder how many more cases of malaria might have resulted if the appropriate mosquito vector, which is widespread in this country, had fed upon the patient (13).

The success of immunization procedures,

Figure 6. Comfort and tolerance limits for physical variables of the environment.

SOURCE: Reference 13.

modern methods for the disinsectization of aircraft, and other public health measures are responsible for holding the spread of disease to a very low incidence in air transportation. With these precautions it is possible that the threat of quarantinable and insectborne disease through air and surface transportation is of less importance to public health than such diseases as influenza and other virus infections. The proximity of passengers in closely confined quarters of an airplane cabin, bus, or railway car, especially when the air is recirculated, would facilitate the spread of airborne infections.

Host-Environment Relationships in Accidents

Many factors in the environment may influence the efficiency and safety of the operators of vehicles. Illumination, bad weather, and

toxic agents such as carbon monoxide are important in highway safety, while temperature, humidity, and ventilation are significant under extreme conditions. Noise and vibration are known to be excessive in certain types of highway vehicles. In aviation, the development of the pressurized cabin is of special interest since it affords an unusual illustration of the relationships between the host, the agent, and environmental factors affecting both health and safety.

Limits have been worked out for many of the environmental variables to show their influence on those who fly in air transports in terms of zones of comfort, discomfort, physiological harm, or intolerability. These are given schematically in figure 6. If the values in the innermost of the three concentric circles are adhered to, perfect comfort is assured. The second circle represents maximum limits for

comfort; hence if these values are exceeded discomfort will result. The outer circle presents values which would be physiologically harmful to the individual if they were reached or exceeded. While the chart has the advantage of brevity and clarity, it may be misleading if the values are accepted too rigidly, for many of them are interdependent. A comfort limit for noise, for example, is apt to be meaningless unless it is related to both frequency and duration. Similarly, the annoying features of vibration are functions of both the displacement amplitude and the frequency. The limits shown for carbon monoxide will be too high if persons are engaged in physical activity or are exposed to the gas while at high altitude (13, 31).

Efficiency of Vision

A significant factor in host-environment relationships is efficiency of vision. In the United States, accident rates per unit of travel are three times higher at night than during the day (7). Presumably, this is due partly to the lower visibility provided by night-time illumination, a contention supported by lower accident rates on lighted highways and by the reduction in rates following improvement of illumination on particular highways.

Older drivers are especially vulnerable in this connection, since the ability to see at low levels of illumination decreases regularly with increasing age. This effect is quite noticeable by middle age and becomes very marked in the elderly. We have calculated that for a dim light or object to be just seen by an eye in the dark, the illumination must be doubled for every increase of 13 years in age (32).

The use of tinted windshields by older drivers may present special hazards at night, since the glass further reduces visibility by reducing the intensity of light reaching the eye (10, 32). Figure 7 shows the increase in light for threshold perception as age increases. Slightly more intensity was needed at all ages when test lights were seen through ordinary clear windshield glass, which here is introduced at 41 minutes. When tinted glass is used, a larger increase in intensity is required. This illustrates in quantitative terms the importance of the interrelationship between factors relating to the host, the agent, and the environment.

Exposure to subclinical concentrations of carbon monoxide frequently leads to effects which may not be noticed by drivers. Even very small amounts of this gas breathed into the lungs are taken into the blood stream, resulting in some degree of oxygen deficiency in the tissues. Early symptoms are lowered alertness, difficulty in concentration, slight muscular incoordination, and a mental and physical lethargy. Reduction of night vision can be demonstrated as one of the first effects (13). These initial symptoms are not permanently injurious, but owing to their nature, they may easily cause hazardous situations. Although, in general, exhaust systems have been improved to prevent the leakage of fumes, appreciable

Figure 7. A comparison of the average dark adaptation curves for eight age groups, each curve indicating the greater sensitivity of the retina as it becomes adapted to darkness.

SOURCE: References 10 and 32.

NOTE: The first 4 or 5 minutes are concerned with cone vision; the remainder of the curve shows the adaptation of the rods. The vertical separation of the curves indicates the increase in intensity of light required for threshold perception (scale at left) as a function of increasing age. Also shown are the slight increase in intensity required when lights are viewed through clear windshield glass (at 41 minutes) and the relatively large increase in illumination needed when tinted windshield glass is placed before the dark-adapted eye (46 minutes). The latter effect may be somewhat more pronounced in the older groups.

concentrations of this gas have been found in the passenger compartment when the car stands with motor idling or moves slowly in dense traffic. Drivers should be well indoctrinated on the need for flushing vehicles with fresh air in such circumstances.

In addition, drivers and airmen should know that certain conditions will intensify the effect of carbon monoxide from engine exhaust (13). For example, the effect of carbon monoxide is obviously more pronounced the higher the altitude. If the blood of a chronic smoker at sea level already contains 5 to 7 percent carbon monoxide absorbed from tobacco smoke, he is affected as if he were a nonsmoker at an altitude of 7,000 or 8,000 feet. Figure 8 shows the combined effect of carbon monoxide and altitude as expressed in terms of the altitude producing an equivalent degree of anoxia. Thus, a person at sea level exposed to air with a partial pressure of 0.06 carbon monoxide would be affected to the same extent as if he were breathing uncontaminated air at 12,000 feet (31). If other oxygenation-reducing factors are present, such as the use of alcohol or certain medicines (sulfanilamide, barbiturate, or acetanilid, for example), the various factors may

combine in their effects, resulting in a significant state of oxygen deficiency seriously jeopardizing safety (8).

Air Transportation of Patients

Patients are using air travel more and more because they can be transported to treatment and surgical centers rapidly.

The Flying Doctors Service of Australia, inaugurated in 1928, clearly demonstrated that the airplane provides an unusually effective way of transporting patients. During World War II the advantage of air travel for the sick and injured was dramatically demonstrated. Only 46 deaths occurred in flight in approximately 1,260,000 patient flights by the U. S. Air Force from all military theaters in the period January 1943 to April 1947.

A study has been made of the passenger deaths in the scheduled airlines of this country from 1930 to 1956. An extremely low rate, less than 1 death per million revenue passengers, has been found consistently. In 1955, for example, there were 22 in-flight deaths in 38 million revenue passengers, or a rate of 0.6 per million (13). Instances of loss of consciousness in flight (table 3) have also been found to be infrequent in comparison with the volume of traffic (33).

The chief precautionary measures for patients undertaking travel by air relate to (a) possible interference with the availability of oxygen and (b) the mechanical effects of the expansion of internal gases. If a physician understands the basic physiological principles involved, appropriate decisions can be made in regard to the advisability of air travel by individual patients (13).

Certain conditions may be characterized by a lowered oxygen saturation of the blood, or a limitation on the transport or utilization of oxygen when the body is placed under stress. Flight may thus be contraindicated or undertaken with caution by patients with certain forms of cardiovascular disease, pulmonary disease, anemia, diabetes, and overwhelming infections or shock, because of additional hypoxia due to altitude.

Among patients with cardiovascular diseases, flight may most frequently be contraindicated for those having limited cardiac reserve, or re-

Table 3. Instances of unconsciousness during flight in United States scheduled airlines, 1947-55, by associated condition and altitude

cent myocardial infarction. Such patients are already under stress to compensate for an insufficient supply of oxygen in heart muscle or are receiving only a marginal supply of oxygenated blood through the general circulation. Experience has shown, however, that altitude is probably not a critical factor for the cardiac patient unless either the disease or the exposure is severe. While those with a history of severe valvular disease, recent coronary thrombosis, or easily provoked angina probably should not fly, individuals with well-compensated heart diseases need not hesitate to fly at moderate altitudes, particularly if cabins are pressurized to about 6,000 feet, or if oxygen is available at all altitudes.

In some pulmonary conditions such as pneumonia, emphysema, and severe asthma, there may be preexisting oxygen want due to mechanical interference with the diffusion of oxygen into the blood in the lungs. In bronchial asthma there may also be oxygen want due to spasm of the smooth muscles of the finer bronchioles. With respiratory embarrassment as well, the individual severely ill with this condition will be unable to cope with the additional hypoxia of even moderate altitudes. The average asthmatic without emphysema, however, is not likely to be affected adversely by altitude.

Serious consequences may result if an anemic person flies at high altitude, and a patient with anemia of even moderate degree might be expected to react poorly to hypoxia because of the

impairment in the oxygen transport system of the blood. Transfusion before flight would be required by many with anemia or leukemia, and oxygen should be supplied from the ground up to patients with those conditions.

Air travel is not contraindicated for diabetics who are fully stabilized and can follow their time schedules for insulin and meals conscientiously. Difficulties may arise from either insulin reaction or diabetic coma. The effects of oxygen want are greatly accentuated when accompanied by low blood sugar, and the reaction may be more severe if fluid and food are lost by the patient because of air sickness.

Certain upper respiratory and thoracic abnormalities and abdominal and neurological conditions may be adversely influenced by the mechanical effects of the expansion of internal gases incident to the decreased barometric pressure at high altitude.

Sinus or otic barotrauma may result in persons with upper respiratory or middle ear disorders since such patients may experience difficulty in equalizing internal and external pressures, particularly during descents. If it is necessary to fly during an acute inflammatory phase, the use of vasoconstrictor drugs is indicated to secure adequate ventilation of the sinuses and middle ear to prevent damage and spread of infection.

One of the most serious contraindications to flight is the presence of pneumothorax. Several deaths in air travel have been traced to the

expansion of a large amount of encapsulated air in pneumothorax patients. If there is free air in the thoracic cavity, the expansion of this air may not only collapse the lung but may also displace the mediastinum, affecting other organs. Tidal air volume is also reduced. The various factors that affect the maximum safe altitude must be calculated for each person on each occasion when he travels. If flight is necessary, it is unwise to start immediately after a refill, and it may be advisable to aspirate the air from the pleural cavity to compensate for the decreased atmospheric pressure during flight.

The expansion of gases trapped in viscera and the abdominal cavity is the basis for contraindicating air travel for about 10 days after persons have undergone extensive abdominal surgery. Intestinal obstruction from any cause presents a serious problem, and if a patient must be transported, procedures to reduce accumulated gases should be followed. Perforated ulcer of the stomach and perforation of the bowel are other conditions that would contraindicate flight at any but low altitudes.

While the hazards of air travel in regard to neurological ailments have been least well defined, difficulties might be expected in patients (a) with air injected for diagnostic purposes, (b) with cranial injuries such that there may be herniation of the brain through openings in the skull, and (c) with conditions in which there may be an increase in intracranial or intraspinal pressures. Marked decreases in atmospheric pressure might be expected to affect such patients adversely. Experience suggests that routine flying as a passenger is not contraindicated for the epileptic whose seizures are controlled by drugs, and there is little indication that blood changes encountered in flight up to 10,000 to 12,000 feet are sufficient to induce seizures.

Effects of Loss of Pressure in Flight

After a sudden decompression at high altitude, passengers would be exposed to severe cold, and a few might develop "bends" if the plane were unable to descend to low altitude within a short time. The low tension of oxygen in the air at high altitude, however, is a limiting factor with the far more serious im-

plications of acute oxygen want. At 40,000 feet, for example, useful consciousness is retained for only 30 to 40 seconds. Even at 25,000 feet most persons would lose consciousness if exposed for 1½ to 2½ minutes unless supplementary oxygen were available (13).

Rapid decompressions have occurred in civil air transportation of the United States at a rate of about 1 incident in 100,000 hours of flying. Fortunately, most of these incidents so far have occurred below 25,000 feet, and planes have been able to descend to low altitudes immediately in almost all instances. In several it was necessary to provide oxygen to passengers showing signs of distress, and at least four instances of loss of consciousness have been reported. It is obvious that a decompression at 40,000 feet would present a very serious problem, and additional precautions will be necessary in the new jet transport equipment designed to operate at 35,000 to 40,000 feet. Unless cabin structures and pressurization are made completely foolproof and as reliable as any major component of the aircraft, it will be necessary to carry emergency oxygen equipment for all on board (34).

Conclusions

Accidents now rank above disease as the chief cause of death and disability to many segments of our population, and now constitute a major threat to the well-being and health of our people.

The accepted function of medicine has been the treatment of disease and injury. Just as the province of medicine has been extended to include the prevention of disease, it is proposed that the prevention of accidental trauma should be a responsibility of preventive medicine and public health.

When accidental trauma is considered a non-contagious mass disease of epidemic proportions, the epidemiological approach should be applied to the study and control of injuries since similar biological principles are involved. An interdisciplinary approach is a basic requirement in this because multiple causation is found in most accidents.

The causes of accidents may be identified in the interactions between the host, the agent (or

equipment), and variables of the environment. If human factors are especially important, and the physician can contribute effectively in the analysis of accident causes because of his background in the biological sciences and his knowledge of human behavior. He can indoctrinate his patients and teach while treating.

Factors of significance to the host in the control of accidental trauma include not only those which determine suitability for a given task such as driving a vehicle or piloting a plane, but also such factors as age, training, and, particularly, personal adjustments. The most promising approach to identifying the accident repeater is based on the concept that "a man works, or drives, as he lives."

The control of various temporary host factors such as fatigue, emotional problems, effects of alcohol, and the influence of disease is highly important. Periodic medical examinations and adequate programs of health maintenance can play a significant role in improving safety both in land and air transportation.

Biotechnology and human engineering should be applied to the design of equipment in order to achieve a closer integration between the operator and his equipment.

The agent of disease also is significant in modern transportation, since insect vectors of disease might be transported in planes and other vehicles and since long journeys may now be completed within the incubation period of most contagious diseases. A review of epidemics attributable to transportation indicates that thus far the spread of disease through air transportation has been less than predicted but that the constant threat to public health must be continually controlled.

Host-environment relationships also have implications for safety in transportation because of the influence upon the individual of physical variables such as the level of illumination, the temperature and humidity, and exposure to carbon monoxide and other toxic agents. Data have been worked out for each of these variables outlining the zones of comfort and discomfort and the ranges where human performance is adversely influenced.

In air transportation, the low tension of oxygen at high altitudes and decrease in barometric pressure with altitude are significant not only

for their influence on the performance of airmen, but also because of their implications for the safety of travel by air by persons who are physically unfit or who are afflicted with certain diseases or physical conditions. These same factors are of critical importance in the development of equipment to transport passengers at very high altitudes because of their significance in the case of a sudden loss of pressurization.

In conclusion, the physician or the public health officer has a direct responsibility for the prevention of accidental trauma. He may contribute most effectively by his aid in carrying out controlled experimental and clinical studies, epidemiological surveys, and by collaborating with specialists in other biological sciences, engineers, and administrative officers in a combined approach to this problem.

1957 Summary of Disease Outbreaks

CARL C. DAUER, M.D.

THE NUMBER of disease outbreaks reported in 1957 for which either water or food was the vehicle of infection was essentially the same as in the past few years (table 1). The number of outbreaks reported by the various States apparently bore no direct relationship to the size of their populations but reflected the extent of activities in investigating epidemic occurrences. The number for a few States was relatively large because of the inclusion of outbreaks occurring on military installations located within their borders.

The method used to tabulate outbreaks was changed slightly from that used in previous summaries. Only those outbreaks with laboratory confirmation of a specific type of food poisoning or food infection were placed in definite categories such as salmonellosis, shigellosis, or staphylococcal food poisoning (table 2). Those without such confirmation were classed as gastroenteritis, etiology unknown. This change accounts largely for the sizable reduction of outbreaks attributed to staphylococcal food poisoning, approximately 50 percent compared with the years 1955 and 1956, when many outbreaks were classified according to clinical and epidemiological findings.

In addition to the usual method of tabulating the number of various types of outbreaks by States, each of the principal types of foodborne outbreaks was tabulated by kind of food involved and by either the place of occurrence or the source of food. As shown in table 3, poultry and other meats were associated with a large proportion of these occurrences. It is also apparent that a large proportion occurred in

groups of persons eating in public establishments and in private homes. However, the average number of persons per outbreak was relatively small as compared with the number in outbreaks occurring in schools or institutions and at social gatherings such as picnics and church gatherings.

No improvements in food-handling practices are apparent. Lack of refrigeration, exposure at room temperatures, or handling of food by persons with infections were mentioned frequently as contributing to or as the direct cause of the outbreak.

Waterborne Outbreaks

Comparatively few outbreaks occurred in 1957 for which water was demonstrated to be the vehicle of infection. In one instance, two persons with typhoid fever had used water from a dug well which presumably was contaminated by a chronic carrier who lived nearby. Gastroenteritis of unknown etiology occurred in two groups of individuals using water from wells that showed evidence of fecal contamination. One small group of cases of gastroenteritis occurred among passengers on an airplane. Inspection of the plane's drinking water supply suggested that it was the probable source of the illness.

Milkborne Outbreaks

Market milk was not reported as the source of infection in any outbreak of disease in 1957. However, two cases of brucellosis were found in one family in which raw milk had been used for a period of about 2 years. A case of Q fever was found in an individual who consumed raw

Dr. Dauer is medical adviser to the chief of the National Office of Vital Statistics, Public Health Service.

milk during a milk strike. Some of the cows in the dairy supplying the milk were shown by laboratory tests to be infected with Q fever.

Milk products, mainly ice cream, were vehicles of infection in six outbreaks. Three of the five involving ice cream were caused by *Salmonella*. Since raw eggs were used in preparing the ice cream in two of these outbreaks, it is possible that they were the primary source of infection. In one instance, cream cheese served in a restaurant was thought to be the probable source of infection for a small group of persons with gastroenteritis.

Typhoid Fever

Only four outbreaks of typhoid fever were reported in which either food or water was definitely incriminated. Two cases occurred among workmen of a small factory supplied with drinking water from a dug well. The well probably was contaminated from a nearby cesspool receiving the stools of a known carrier. An explosive outbreak totaling 38 confirmed and 27 suspect cases of typhoid fever occurred in an institution. The outbreak was considered to be foodborne since the water supply was found satisfactory in every respect. One of the persons living in the institution was found to be a carrier. It was determined that she carried the same phage type (E_1) organism that was found in a number of the cases. In another outbreak of 17 cases, 14 were confirmed by isolation of a phage type (E_1) organism. All of the patients were members of the 7th grade of a public school. The manager of the cafeteria in the school was found to be a carrier and is presumed to be the source of infection, but the mode of contamination or the specific food involved was not determined. In another instance of 13 cases all of the patients had eaten in a restaurant where a carrier, not previously known, was employed as a busboy.

A group of three cases, not included in the tables, occurred in preschool children living in the same apartment building. A known carrier lived in this building, and another lived in another part of the housing development, but neither had any known contact with the

children. The organisms recovered from the first carrier and the children were all shown

to be phage type E₁. Overflow of sewage from the building into the basement was pumped out on a lawn used by the children as a play area. It is possible that the children were infected on the playground. In another area, floods occurring in late spring washed out sewer mains and covered the sewage treatment plant of a large city. Seven cases are believed to have resulted directly or indirectly from this interruption of sewage disposal. One case in the same city was considered to have resulted from a fall into the river when it was highly polluted with sewage.

Salmonellosis

Thirty outbreaks of salmonellosis were reported in 1957, all of which were confirmed by

recovery of organisms either from the stools of those who were ill, from food handlers, or from specimens of food. In six of the outbreaks, poultry meat—usually turkey—was eaten. A comparatively large number of the outbreaks occurred in homes. The smallest consisted of 3 cases and the largest of 70 cases following a wedding reception at which turkey was served. One large outbreak occurred simultaneously among persons attending dinners in several churches of one community. The food served by a single caterer from another State was transported about 400 miles in this outbreak.

Fifteen types of *Salmonella* organisms were isolated in the 30 outbreaks. Among the types recovered were *S. typhimurium* in 11, *S. newport* in 4, *S. montevideo* and *S. tennessee* in 2

each. In one outbreak 2 types, *S. give* and *S. sandiego*, were recovered; in another, 3 types, *S. barielly*, *S. montevidео*, and *S. reading*.

Early in 1957 it was noticed that an unusual number of *S. reading* infections were occurring. A sharp rise in the number began in September 1956 and reached a peak of 71 cases in February 1957. Infections were identified almost simultaneously in several widely separated areas of the country. During the 12-month period beginning in September 1956, there were 325 acute, sporadic cases and 3 outbreaks due to this type of organism. Previously *S. reading* was very rarely identified among the *Salmonella* isolates from human or animal infections occurring in the United States. Of the cases reported, 70 percent were in children 6 years of age or under and 18 percent in children under 1 year. The epidemiological picture strongly suggested a widely distributed common source of infection, but despite intensive investigation by means of detailed food histories, no common vehicle was identified.

Shigellosis

Eleven outbreaks of shigellosis were reported in 1957. Water was not regarded as the vehicle in any of them. As shown in table 3, three of them involved eating in public eating places, two occurred in institutions, and two in schools. The food involved in transmission of the infection was not determined in 7 of the 11 outbreaks. *Shigella sonnei* was recovered in 2 outbreaks, *Shigella flexneri* in 4, and the species was not stated in the remaining 5.

Trichinosis

Three relatively small outbreaks of trichinosis were reported in 1957. In one family outbreak comprising 4 cases, sausage or chopped beef that may have been contaminated in a meat grinder was the probable source of infection. Four other cases, proved by biopsy, followed consumption of homemade garlic sausage. Consumption of raw pork and liver preceded acute trichinosis in 6 patients, 3 of whom died. Numerous trichina larvae were found at autopsy of two and by muscle biopsy

in others. Calcified cysts indicating previous infestations were found in some of the specimens. Specimens from a slaughtered pig also showed numerous trichina larvae.

Botulism

Six separate reports of botulism afflicting 12 persons were reported in 1957. Home-canned foods had been eaten in each instance. These included a gluten preparation, sausage, mushrooms, stringbeans, corn, and tuna fish. The type of infection was reported in only one instance, type A botulinus toxin being found in the tuna fish. Four of the 12 persons with botulism died.

Staphylococcal Food Poisoning

Most of the 58 outbreaks of staphylococcal food poisoning reported occurred in groups of persons who had eaten in public establishments or in private homes, or had consumed food obtained from bakeries and caterers. Poultry and other meats were most commonly associated with these outbreaks. Eclairs and custard-filled cakes and pies were proved by laboratory tests to be the vehicles of infection in only 10 outbreaks. These types of food were suspected in 12 additional episodes, but the cases were tabulated as gastroenteritis, etiology unknown, because laboratory confirmation was not obtained.

Streptococcal Infections

Four relatively large epidemics of streptococcal infection were traced to food eaten at social gatherings. In one instance, it was estimated that about two-thirds of the 900 who attended a charity luncheon became ill with septic sore throat. Egg salad served at the luncheon was considered to be the vehicle of infection. In another epidemic which occurred among those attending a social, the potato salad was found to contain large numbers of streptococci. Symptoms of gastroenteritis characterized the illness. Thirty persons became ill with cramps and diarrhea following a church picnic where chicken salad was served. This food contained streptococci. Following a school picnic in another area, large numbers of strepto-

cocci were found in meat loaf, potato salad, and coleslaw served to the children, 100 of whom developed gastroenteritis.

Gastroenteritis, Etiology Unknown

The number of reported outbreaks with unknown etiology constituted more than half of the total of foodborne and waterborne outbreaks. In about 45 percent of them, poultry and other meats were considered the vehicles of infection. About the same percentage occurred in persons eating in public eating establishments and in private homes. In most of the 132 foodborne outbreaks, investigators were unable to obtain specimens of food for laboratory testing. In a small number, specimens were obtained but showed none of the organisms usually associated etiologically with food infection or food poisoning.

Chemical Poisoning and Noxious Foods

In one of the four reports of chemical poisoning, 3 persons showed clinical signs of acute lead poisoning. They had cramps and diar-

rhea and complained of a metallic taste after eating duck meat. The ducks had been shot and stored in a freezer for 2 months. A laboratory test showed the presence of lead in leftover portions of the duck meat. In another outbreak, lemonade prepared in a cadmium-lined can produced illness in every person who drank it at a school picnic. The lemonade contained 62.7 ppm of cadmium, and vomitus from patients contained 15.0 ppm of the metal. A case of poisoning occurred in one child who ate chocolate-covered ice cream, on a stick. A washing powder, sodium metasilicate, may have spilled into the molds used in making the ice cream sticks, or it may have remained in the molds after cleaning. In another instance, 16 persons became ill shortly after eating breakfast on an excursion boat. The type and source of toxic agent could not be determined.

In four outbreaks reported, ingested foods produced toxic symptoms. In two instances, mushrooms were eaten. Castor beans caused illness in another. Consumption of smoked fish was reported as the probable cause of acute toxic symptoms in six persons.

Conference on Staphylococcal Infections

A conference on staphylococcal infections will be held at the Communicable Disease Center of the Public Health Service in Atlanta, Ga., September 15-17, 1958.

Representatives of 40 hospital, medical, and other professional organizations will confer on control measures that can be established in hospitals and communities to deal with the mounting problem of infections caused by bacteria which are resistant to penicillin and other antibiotic drugs.

The conference, recommended by the American Hospital Association, will be sponsored by the National Research Council and the Public Health Service.

In comparison with other members of HIP, those over 65 have a higher rate of physician visits. Greater use of services from both specialists and family physicians and more visits in the hospital account for the differences.

Experience With Older Members in a Prepaid Medical Care Plan

SAM SHAPIRO, B.S., and MARILYN EINHORN, A.B.

VOLUNTARY health insurance for older people (those 65 years and over) has expanded in recent years but still lags behind coverage for the population of the United States as a whole. It is estimated that in 1955 about 65 percent of the total population had some type of health insurance (1), while only about 41 percent of the noninstitutionalized aged were covered (2).

Reduced incomes, retirement, and enrollment restrictions are among the reasons why most of the aged do not have health insurance. Also contributing is the fact that when many of today's older people were in the labor force health insurance was not so widespread as it is now.

The need for finding ways to extend the benefits of voluntary health insurance to more of the aged is generally recognized as acute and is receiving attention by government, employer and union groups, and the prepayment plans (2).

Mr. Shapiro is assistant director, and Miss Einhorn is a statistician on the staff, division of research and statistics, Health Insurance Plan of Greater New York, New York City. Previously, Mr. Shapiro was in the National Office of Vital Statistics, Public Health Service. His co-author was formerly with the Committee on Veterans Medical Problems, National Academy of Sciences-National Research Council.

Necessary in considering solutions to this problem is information regarding requirements and expenditures for medical care of the aged. In the last few years, this type of information has expanded significantly through studies of general population groups (3). An item about which a great deal more knowledge is needed, however, is the experience of health plans that currently enroll the aged.

The Health Insurance Plan of Greater New York is such a plan. A prepaid voluntary plan now about 11 years old, HIP is organized on a group practice basis and provides comprehensive medical care. Persons covered are entitled to receive medical care from family physicians and specialists in the office, the home, and the hospital. The insurance pays for preventive and diagnostic medical services and for treatment of illness. Laboratory, radiological, and other diagnostic tests as well as physical therapy and services of visiting nurses are included. The only medical services excluded are treatment by a psychiatrist, purely cosmetic surgery, care for drug addiction, anesthesia, and care for chronic illnesses in institutions other than general hospitals.

There are no waiting periods for service in HIP, no exclusions from enrollment because of preexisting conditions, and no limitations on the number of services or duration of medical

Explanatory Notes

Statistics in this report are derived from an enrollment card prepared for each HIP subscriber and from a physician's report form on which the physician records information about each contact with an HIP member. The enrollment card gives the age, sex, and a history of all changes in coverage status for each person insured. The physician's report includes statistics on the age and sex of patients as well as information on where the service was given and the medical specialty.

Physician visits. In general, physician visits refer to face-to-face contacts between the physician and the patient in the office, home, or hospital. Each preoperative visit and each postoperative visit, as well as the operation itself, is considered one physician service. Similarly, each prenatal visit and each postpartum visit is counted as one service.

In counting services of radiologists each reading of an X-ray film of a body part and each field treated with deep roentgen therapy is considered one service. Also counted as one service is each visit for superficial therapy irrespective of the number and location of the fields treated.

Physician visit rates. The average number of physician visits per person per year is obtained by

relating the number of visits to HIP physicians during the year to the average number of persons enrolled in the plan. Average enrollment is the total number of person-months of coverage in a year divided by 12. This, in effect, takes account of the fact that some members are in the plan for only part of a year.

Sampling ratios. Tables showing enrollment and physician utilization experience are based on sample tabulations. The sampling ratio for a specific set of data is indicated in a footnote to the pertinent table. To reduce sampling variability, data are usually combined for a 2- or 3-year period.

Hospitalization rates. Hospitalization rates reflect experience of a 20 percent sample of HIP subscribers who are employees of the city of New York and their dependents enrolled in HIP throughout 1955. All of the enrollees have Blue Cross hospital insurance. Data regarding hospital admissions and length of stay in 1955 were obtained from the claim files of Blue Cross and refer to all hospitalizations in the group, regardless of the type of hospital (voluntary, proprietary, or municipal) or whether the physician was associated with HIP.

care. Medical services are provided by physicians associated with 32 medical groups. Each medical group receives an annual capitation payment for each insured person in that group. Members receive no bill for medical services, the premium paying the entire cost. (The only exception is a possible \$2.00 charge for a night call to the home between 10 p.m. and 7 a.m.)

Enrollment Composition

On June 30, 1957, there were 513,052 persons enrolled in the Health Insurance Plan. About 67 percent were employees of New York City and their dependents; 19 percent were insured through health and welfare plans established by labor groups; 7 percent had converted from group to individual contract; and the remaining 7 percent came from a variety of small employment groups and housing projects.

Initial enrollment is on a group basis only, the usual requirement being that at least 75 percent of those eligible enroll. Contracts ordinarily provide for coverage of the employee (referred to in this report as the subscriber), spouse, and dependent children under 18 years of age. However, a number of union health and welfare plans have signed contracts providing coverage only for the employee. On June 30, 1957, 7.2 percent of HIP's members (subscribers and dependents) were under this type of contract.

Two provisions in the enrollment regulations of HIP are particularly important to older people. First, there are no exclusions because of age or physical condition. Second, any subscriber leaving his group, because of change of job, retirement, or the like, may convert to an individual contract without any loss in benefits. This privilege to convert is not restricted in

any way, not by age, medical condition, nor previous use of services.

In 1957, 23 percent of HIP's members aged 65 years or over had individual contracts as compared with 5.4 percent for all other ages. The age and sex composition of the aged converttees more closely approximates that of the older people in the general population than does the composition of the aged under group contract. More than half of the aged who had converted are over 70 years old, whereas only a fourth of the other aged in HIP are that old (table 1). Also, women constitute a higher proportion of the converttees 65 and over than of the aged under group contract.

Despite the comparatively high percentage of older people with individual contracts through conversion, the proportion of HIP's total enrollment that is 65 years or over (3.6 percent) is substantially lower than the figure for New York City as a whole (9.1 percent). This differential is not surprising since the source of HIP's subscribers is basically employment groups. In time, it might be expected that the conversion privilege would result in a narrowing of the differential. However, there are important deterrents to this process, as discussed in the next section.

Maintenance of Coverage

Experience during the period 1952-54 indicates that each year about 20 percent of the

aged subscribers under group contract are listed for termination of enrollment (table 2). Mortality accounts for almost a fourth of this group. The remaining 16 percent may be listed for termination because the subscriber left his employment group or because he decided to drop HIP. Considering the age group, the principal factor would appear to be retirement from the labor force. (For a detailed analysis of termination rates, based on 1948-51 experience, see reference 4.)

Of the 16 percent listed each year for termination for reason other than death, close to two-thirds fail to convert from group to individual coverage. Since retirement from the labor force is in prospect for all the aged, this rate of loss means that most subscribers at advanced ages drop their insurance. The loss among subscribers under 65 listed for termination is also high (81 percent), but future medical insurance coverage for this group is a distinct possibility, through new jobs or through employed spouses, for example. On the other hand, coverage for the aged once their enrollment has terminated is very unlikely.

The high loss in coverage among subscribers 65 or over is undoubtedly due in part to the financial burden conversion represents. The premium rate under individual contract obtained on conversion is only slightly higher than the rate under group contract. For a two-person family, for example, a group contract costs \$85.45 a year, and an individual contract, \$90

Table 1. Age, sex, and enrollment status of HIP members, June 30, 1957

Age and sex	Number of members			Percentage distribution of members		
	Total	Individual contract by conversion	Group contract	Total	Individual contract by conversion	Group contract

¹ Subscribers under group contract except those under contracts with special provisions for insuring the aged on retirement. Subscriber is the person (usually an employee) through whom the family obtained the insurance.

² Based on a 2 percent sample of changes in enrollment status.

³ Based on a 10 percent sample of changes in enrollment status.

⁴ The group for whom a change in status from group enrollment to either individual enrollment or discontinuation in coverage is required.

Occurs when subscriber leaves his group because of retirement or loss or change of job, death, or decision to drop HIP insurance.

⁵ Mortality estimated on basis of rates for white males and white females in Middle Atlantic States, Life Tables for the Geographic Divisions of the United States, 1949-51, Vital Statistics—Special Reports, vol. 41, No. 4, 1956.

⁶ Percent of subscribers listed for termination, excluding deaths.

(not including costs for hospital insurance). The difference, however, is not usually the total increase in out-of-pocket cost to the subscriber, since the great majority enter HIP through group contracts in which part or all of the premium (most often half) is paid by the employer or the union health and welfare fund. On conversion, the subscriber must pay the total premium himself. Thus, on retirement from the labor force the aged are usually faced with a substantial increase in cost of health insurance at a time when their income is reduced and, as will be shown, when their medical needs are great.

Finding ways to permit the aged to maintain their insurance is a major challenge to the community, employer and labor groups, and voluntary health agencies. Steps have already been taken by a number of health and welfare funds to retain the aged employee as part of the group after retirement and to continue paying the premium, but this arrangement is the exception rather than the rule. Only 10 percent of the subscribers in mid-1957 were enrolled by contractor groups that continue to pay the premium after the employee retires.

What about the subscribers who do convert? How long do they remain covered? At the end of the first year, 89 percent of the aged convertees are still in HIP. The rate of attrition diminishes in succeeding years, and by the end of the fourth year 76 percent remain excluding the loss due to death (table 3).

Among subscribers under 65 who convert, the pattern of retention of coverage in HIP is quite different from that for the aged. Only 73 percent are left after a year and 61 percent after 2 years. The loss becomes negligible after that, and 59 percent of these subscribers are in HIP for 4 or more years after conversion.

The far greater loss in the first year among subscribers under 65 than among the aged may well reflect a difference between the two groups in the type of services they anticipate. The aged may expect to need medical care of long duration, whereas the group under 65 will more

Table 3. Retention of coverage by HIP subscribers after conversion to individual contract, 1952-54

⁴ Based on a 10 percent sample of changes in enrollment status.

likely require short-term care, such as obstetrical or pediatric services. Furthermore, other opportunities for group enrollment may appear for the subscriber under 65, but not for the aged.

Volume of Services

The amount of medical care an HIP member receives is unrestricted by administrative regulation. Members are encouraged to use medical group service efficiently and to employ sound health practices based on current scientific knowledge through a varied and continuous educational program which HIP's division of health education has helped each medical group to develop.

In this setting, one might expect a pattern of medical care behavior different in some respects from that of the general community. The results of a household survey conducted in 1952 suggest that this is indeed true (5). This study indicates that the proportion of HIP members who see a physician sometime during the year is higher than the figure for the total popula-

tion of New York City, 69 percent as compared with 57 percent. The time between onset of illness and when a doctor is seen seems to be somewhat shorter for persons covered by the plan, but once having seen a physician for a particular ailment HIP members appear to make fewer visits than do persons in the city as a whole. These findings provide a broad, general background for interpreting the rates of medical care presented in the rest of this report.

Seventy percent of the members 65 years of age and over see an HIP physician at least once during the year (table 4). This is about the same proportion as in the age group 45-64 years, but it is somewhat below the figure for younger adults and appreciably lower than the figure for children. The finding that 3 in 10 of those of middle and advanced age do not see a doctor during the year is of particular interest because of the special emphasis on the value of periodic medical examinations at these ages. It is apparent that the availability of comprehensive medical care with no economic deterrent does

Table 4. Physician visits by age, sex, and conversion status of HIP members

¹ Data apply to subscribers enrolled in HIP throughout this period and their dependents who were insured on June 30, 1956.

² This figure differs somewhat from the rate (5.3) based on 100 percent counts.

NOTE: Data based on a 10 percent sample of the HIP enrollment.

not, by itself, insure the use of preventive services.

Despite the comparatively low proportion of older members who see a physician, the average number of visits this group makes during the year (7.3) is 40 percent higher than the rate for HIP as a whole (5.2). The difference results from the fact that more of the older people than of other age groups receive large volumes of service. Among the aged 8.3 percent see a doctor at least 20 times in a year as compared with 4.2 percent of all members. Another point of interest is that aged members who receive this many services account for almost half the care (47 percent) obtained by the entire group 65 or older.

The rate at which physicians' services are received is higher among the aged not only as compared with all HIP members but also as compared with any other 5-year age group (see chart). The high rate at the older ages, however, does not represent a sharp departure from the experience at earlier ages, but rather is the end point of an upward trend in the rate after ages 35-39.

This difference between older persons and others in physician utilization is a decided change from the experience of HIP in 1948 and 1949. During this early period, the aged received physicians' services in HIP at only a

slightly higher rate, about 10 percent, than all members (6). The 1948-49 experience may have been strongly influenced by special factors applicable to the first few years of the plan, for example, greater dependence of the members on physicians not in HIP than is true today.

Utilization of physicians' services differs among men and women 65 years and over. At these ages a higher proportion of the women than of the men see a doctor during the year, but the relative volume of services is greater among the men. Among all other adults the rate at which women see a doctor is either the same as for men or higher. Actually, the rate for women in HIP is greater at the high fertility ages of 20-29 than at the advanced ages. Among adult males the rate at ages 65 and over is far above that at any other age.

Particularly illuminating are the figures in table 4 on physician visits for two categories of the aged, those who have converted to individual contract and those under group contract. Utilization, it will be noted, is much higher in the former group (who are older on the average) with respect both to the proportion who see a physician during the year and to the average number of such visits. This type of differential is not peculiar to the aged, as indicated by the data for those under 65. It may result

Physician visit rates by age and sex of HIP member, 1955-56

¹ Rates for persons under 65, not shown separately, closely approximate the rates for all ages.

² Includes specialists not shown separately.

³ Includes pediatricians' services. Exclusion of these

services reduces the family physician rate for all persons to 243.8 and the rate for children under 15 to 196.8.

NOTE: Data based on a 10 percent sample of the HIP enrollment.

to a considerable extent from self-selection on the part of a subscriber, whether or not aged, when faced with a choice of converting to individual enrollment or dropping his insurance.

In view of the comparatively high requirements among the aged for physicians' services, the question might well be asked, what would happen to the volume of physician services in HIP if the aged were represented in the plan in the same proportion as they are in the general population? Some indication of the result can be obtained if it is assumed that (a) the rate of visits found among the aged on group contract is applicable to all the aged in the city's labor force and (b) the rate for those who converted to individual contracts is applicable to all of the noninstitutionalized aged not in the labor force. Under these assumptions, increasing the proportion of the aged in HIP from 3.6 percent to 9.1 percent would raise the average number of physician visits per member per year from 5.2 to 5.5.

The impact of this relatively small increase on the operations of a medical care plan may not be reflected entirely by what happens to the overall rate. A full assessment would require, among other things, currently unavailable data

on ancillary services to the aged and knowledge about the kinds of physicians' services this age group receives. The latter is discussed in the sections that follow.

Specialists' Services

Associated with each medical group in HIP are physicians in 12 basic specialties. The opportunity to call on a specialist is one of the most important advantages of the plan both to the member and to his family physician.

As medical problems vary with age, so do requirements for services from specialists. Throughout adult life, visits to all but a few of the specialists increase to reach a peak among the aged (table 5). Utilization of surgeons, internists, and urologists is especially high at ages 65 and over as compared with the rates for all ages combined.

Paralleling the increase in the requirement among the aged for care from the specialist is the greater volume of services that the family physician is called on to give. While the average number of visits to the family physician for older persons is 4.1, the corresponding figure for adults in each of the 2 age groups shown in table 5 is less than 3.0 per person.

The pattern of utilization of medical services is very similar among men and women 65 or over in a number of important respects. The rates for the two sexes are virtually the same in the use of family physicians, ophthalmologists and otolaryngologists, and radiologists (table 6). However, the men have a substantially higher rate of service from the internists and, of course, from the urologist, while women see the orthopedist more often.

No specialty can be identified as bearing a particularly heavy part of the greater utilization by the aged who have converted to individual contract as compared with the aged under group contract. The rate at which general physicians are used increases by about the same proportion as the rate for all services, and major increases occur in a wide range of specialties, including internal medicine, surgery, and radiology.

Place of Service

The proportions of physician visits that take place in the office, in the home, and in the hos-

pital differ greatly according to age. The outstanding characteristic of the pattern among the older people is the exceptionally high proportion of visits in the hospital, 21 percent as compared with 11 percent for all ages. The difference is even greater on a rate basis. Services in the hospital are received from HIP physicians by the aged at the rate of 15½ per 100 members, which is almost three times the rate of 57 for all persons in HIP (table 7). Contributing to the high rate for the aged are both high hospital admission rates and long hospital stays (table 8).

The average number of visits to the physician's office is likewise greater among those 65 and over, but the margin is far smaller than is found in hospital care. Although the home call rate for the aged is higher than for other adults, it is slightly below the rate for persons of all ages, which is affected markedly by frequent home visits to children.

Among the aged, men utilize physician services in the hospital at an appreciably higher rate than do women (table 7). The differential

Table 6. Physician visit rates by type of physician for HIP members of specified age, sex, and enrollment status, 1955-56

Type of physician, by sex of HIP member	Number of physician visits per 100 persons per year

² Includes specialists not shown separately.

³ Includes services by pediatricians. Exclusion of

these services reduces the family physician rate for all males to 235.3 and for all females to 252.5

NOTE: Data based on a 10 percent sample of the HIP enrollment.

is due entirely to a wide gap in hospital admission rates for the two sexes, the average length of stay being virtually the same. The

relationship between the rates of service in the hospital for men and women is not repeated for services in the office or at home. In fact,

Shapiro, Hospital Monograph Series No. 3, Chicago, American Hospital Association, 1958.

care in the home is received relatively more often by aged women than by aged men.

As pointed out previously, among members both over 65 years and under that age those who have converted to individual contract use physician services at a considerably higher rate than the group subscribers. This difference results from more frequent use of physicians' services not only in the office but also in the home and in the hospital (table 7).

One of the most interesting utilization experiences among the aged converttees is the rate at which the men receive physician services in the hospital. This figure (324 per 100 persons per year) is more than twice the rate among aged men under group contract (155) and several times the average for HIP as a whole (57).

Hospitalized Surgery

The rate of operations performed in the hospital is higher for the aged (45 per 1,000 persons per year) than for all HIP (35 per 1,000) (table 9). The differential is far smaller than that in the rate for all hospital admissions, but it represents a difference of 27 percent, a not inconsequential margin.

The surgery rate is comparatively high in the aged group mainly because of the high rate for men. The rate for aged women (36 per 1,000) is near the average for all females (34) and, in fact, is slightly lower than that for other adult females. On the other hand, the rate for aged men (50) is well above the figure for men at younger ages.

Unlike other categories of utilization, hospitalized surgery for the aged is not more frequent among the converttees than among persons covered by group contracts. The rates are nearly the same, 43 and 45 per 1,000 respectively.

Requirements for surgery are only partly defined by total rates. Detailed data regarding operative procedures are needed for complete analysis. Only a few such data are now available. As indicated by the rates in table 9 for broad categories of procedures, the aged differ substantially from persons of all ages in the types of operations they undergo.

Gastrointestinal, abdominal, and genitourinary operations account for about three-fifths of the hospitalized surgery among the aged as compared with two-fifths of the surgery at all ages. Furthermore, from the limited data

Table 9. Hospitalized surgery rates for HIP members, by type of operation and age and sex, 1956

³ Includes circumcision of newborn. Exclusion of

these procedures reduces the rate for all males to 4.4 and the rate for males under 15 to 3.5.

NOTE: Data based on a sample consisting of all operations performed in hospitals during alternate months in 1956.

available, it appears that the nature of the operations within broad categories differs with age. This is illustrated most clearly with respect to eye, ear, nose, and throat operations. In this category two-thirds of the operations among the aged are for cataract and glaucoma (3.4 per 1,000 persons over 65) whereas at younger ages by far the most frequent surgical procedure is tonsillectomy (5.0 per 1,000 persons under 65).

Summary and Discussion

The enrollment and medical care experience of the aged in the Health Insurance Plan of Greater New York has been examined from a number of standpoints bearing on current discussions of health insurance for the aged. In generalizing it is important to keep in mind the characteristics of this medical care plan. It is prepaid, comprehensive in coverage for all medical services, and it provides care through medical groups. There are no restrictions on enrollment because of age or preexisting conditions. Initial enrollment is principally through employment groups, but subscribers leaving their groups have an unrestricted privilege of converting to individual contract.

The outstanding feature of HIP's enrollment experience with aged subscribers is that despite the conversion privilege most of those who must decide whether to convert or to terminate coverage drop their insurance. This situation illustrates the paradoxical position of many members of health insurance plans when they reach retirement age. Group coverage is obtained while they are employed and for an increasing proportion of them under arrangements whereby the employer or a health and welfare fund pays at least part of the premium. On leaving employment, many of the subscribers are faced with the dual economic problem of reduced income and increased out-of-pocket costs to maintain their insurance. And this occurs at a time when their medical needs are increasing. A pertinent question for the community is where and how do the aged whose health insurance is terminated obtain medical care. It would be of much interest, for example, to determine the extent to which former HIP enrollees become dependent on hospital clinics and ward facilities.

With respect to the medical care requirements of the aged, HIP's experience affords several observations:

1. The aged see a physician on the average considerably more often than do persons of all ages combined. The rates are 7.3 physicians' visits per member per year for the aged and 5.2 for the total enrollment. The older people who have converted to individual contract average 9.3 visits to a physician per year.

These rates are unquestionably high, but they are not quite so forbidding when it is realized that the rates are also high in other age groups (60-64, 20-29, and under 5 years). Viewing voluntary health insurance as a community institution, it is appropriate to consider what would happen if the aged were represented in HIP in the same proportion as in the total population. In New York City, this would mean an increase in the aged subscribers from 3.6 to 9.1 percent, and an estimated rise in the rate of physician visits of 6 percent (provided the aged added to HIP were representative of all the noninstitutionalized aged in the city). This is a small quantitative increase, but its true impact on the medical care plan cannot be fully assessed without information about the qualitative aspects of the care received by the aged.

2. Most of the medical specialties are affected by the comparatively high medical requirements of the aged. The greatest effect is on the surgeon, the internist, and the urologist. Of equal significance is the fact that the family physician continues to occupy a central position in providing medical care to the aged. Thus an increase in enrollment of the aged would require not only an expansion, in varying degrees, in some of the specialties but also the addition of family physicians.

3. Extensive use of hospital care is a major reason for the comparatively large volume of physicians' services received by the aged in HIP. More than a fifth of the contacts the aged have with the physician (21 percent) take place in the hospital; the corresponding figure for members of all ages is 11 percent. A higher surgery rate is an important factor in this situation, although there are indications that admissions for services other than surgery contribute more to the high hospital rate. The type of operation performed on the aged differs from

the type for younger persons. This may have greater bearing in evaluating the surgical requirements of the aged than the general rates of operations performed. A full exploration of this point is dependent on the development of data concerning specific operations.

Arthur S. Flemming, Secretary

Marion B. Folsom, Secretary of Health, Education, and Welfare, resigned from his post July 31, 1958. Mr. Folsom became Secretary August 1, 1955, after having served as Under Secretary of the Treasury for 2½ years.

He had previously been active in social security programs for more than 25 years.

In 1928, he developed a life insurance, retirement, and disability plan for employees of Eastman Kodak Company and 3 years later Mr. Folsom developed an unemployment benefit plan which included 13 other companies in Rochester, N. Y.

His work in Federal social security began with membership on the President's Advisory Council on Economic Security which helped draft the original Social Security Act in 1934.

In 1942 he helped organize the Committee for Economic Development, of which he later became chairman, and in 1944-46 he served as staff director for the House Committee on Postwar Economic Policy and Planning.

During his tenure with the Treasury Department, he worked with the Department of Health, Education, and Welfare on a study of old-age and survivors insurance resulting in extension of coverage and liberalization of benefits under the 1954 amendments to the Social Security Act.

Arthur S. Flemming, president of Ohio Wesleyan University since 1948, succeeds Secretary Folsom. While on leave from his university post, Mr. Flemming served as director of the Office of Defense Mobilization, during 1953-57, and as assistant to the Director of that agency in the years 1951-53.

A member of the United States Civil Service Commission during 1939-48, he was also chief of labor supply in the Office of Production Management in 1941-42, chairman of the Management-Labor Policy Committee of the War Manpower Commission during the next 4 years, and on the Manpower Survey Board of the Department of the Navy in 1943 and 1944.

Mr. Flemming was twice a member of the Commission on Organization of the Executive Branch of Government, during 1947-49 and again in 1953-55, and served as chairman of the Advisory Committee on Personnel Management of the Atomic Energy Commission from 1948 to 1953. He has been a member of the International Civil Service Advisory Board since 1950 and of the President's Advisory Committee on Government Organization since 1953.

From 1930 to 1934, Mr. Flemming was on the editorial staff of the publication now known as the *U. S. News & World Report*.

Nursing Home GOALS

The First National Conference on Nursing Homes and Homes for the Aged, called by the Public Health Service, was held February 25-28, 1958, in Washington, D. C. Some 150 persons, representing individual homes, social service organizations, State health and welfare departments, and 32 national associations met to discuss measures for improving services to the chronically ill and aged. The goals set by the participants, their recommendations on how these goals can be reached, and three of the addresses at the conference are summarized on the following pages. The full proceedings are being published by the Public Health Service.

Achieving the Goals

The Federal role in achieving the goals of this conference is necessarily an auxiliary one, affording certain aids and opportunities that are valuable only to the extent that they are used, creatively and imaginatively, by the States and communities. A review of current activities of the Public Health Service and other units

This summary is based on a paper presented by David E. Price, M.D., chief, Bureau of State Services, Public Health Service.

of the Department of Health, Education, and Welfare as they relate to these goals may spark your thinking on ways you can use existing aids to greater advantage and suggest to you recommendations for additional activity which we could legitimately undertake.

Goal 1. Several national studies, completed, in progress, or planned, should help to advance this goal. One of them, already published, is especially pertinent: *Nursing Homes, Their Patients and Their Care*. Knowing the characteristics of the people in these homes is an important first step toward determining the services and facilities they require.

Other studies now under way, such as the U. S. National Health Survey which began in July 1957, and the sample survey of Old Age and Survivors Insurance beneficiaries which will be conducted this year, can be expected to give us additional data that will be helpful.

Goal 2. Perhaps the most notable contribution the Federal Government has made in this area is the so-called standard-setting amendment to certain public assistance titles of the Social Security Act. Prior to this legislation, there was no way substandard homes could be forced to provide at least the essentials of decent living for older people. Now, all States have regulatory authority over most types of homes even though all States do not have it for all types of homes. Licensing authorities in both the State welfare departments and the State health departments have recognized that the most important contribution they can make to the improvement of services is not through the use of police power, but through the assistance they can offer home operators.

Goal 3. The Federal Government has been active in many facets of the knotty financial problems involved in improving the services and facilities of nursing homes.

The Hill-Burton program provides a strong financial incentive to States and communities to create much needed facilities. Since 1955, about \$21 million in matching funds have been provided annually for construction of facilities primarily serving patients with long-term illnesses. Four hundred projects, adding 3,900 chronic disease beds, 4,500 nursing home beds, and other facilities, were aided by these special funds.

Public assistance financing has also been liberalized. Legislation in 1956 not only increased the Federal share in assistance payments but also provided a separate formula and additional funds for medical care.

Here again, however, there are wide variations in the value an area receives for its Federal aid dollar. For example, with the constantly increasing number of older people in the population, general hospitals, planned, staffed, and organized to provide costly care for patients with acute illness, find that more and more of their beds are occupied by long-term patients.

Conference Goals

1. To determine the essential elements of service in the different classifications of homes.
2. To delineate more clearly ways in which accrediting, standard-setting, and regulatory agencies may assist in improving the quality of care in nursing homes and homes for the aged.
3. To encourage a more realistic attitude in financing the cost of facilities and services provided by nursing homes and homes for the aged.
4. To explore the need for and methods of providing public, professional, patient, and family education.
5. To explore ways and means of providing consultative services and assistance to administrators and staffs of nursing homes and homes for the aged.
6. To set guidelines for future action.

Many of these same patients could be cared for at far less cost in nursing homes where medical care is available.

Similarly, public assistance payments for medical care are often much higher than they would need to be if the community were willing to invest more in public health programs that prevent the development of chronic diseases, retard their progress, and minimize their effects. Multiple screening projects for the early detection of chronic conditions would reduce the need for institutional care. Rehabilitation programs, planned cooperatively by health and welfare agencies, hospitals, homes, and physicians, would help to reduce the time period when costly medical and nursing care is required.

Goal 4. In the field of professional education, we can already count solid gains: the Public Health Service traineeship programs for nurses and public health personnel into which some \$5 million is being invested this fiscal year and the authorization for a program of grants to States for extending the number of trained public assistance personnel, to mention only two of the most recent ones.

Another educational approach is through publications. For example, there is now available an illustrated booklet showing in detail the exercises that will help stroke patients. This will make it possible for the general practitioner, his patient, and the patient's family to work out a regimen of exercises. The new diet booklets prepared for heart disease patients on sodium-restricted diets, sponsored by the Public Health Service and a number of voluntary and professional agencies, are designed for the same type of use. Other examples are the manuals *How to be a Nursing Aide in a Nursing Home*, produced cooperatively with the American Nursing Home Association, and *The Older Person in the Home*, and, of course, the periodical *Aging* which is issued by the Department's Special Staff on Aging.

Goal 5. The Public Health Service last year received from Congress an additional \$3 million in general health grants to assist States to develop programs in chronic disease and other health areas not covered by the traditional type of public health activity. A gratifying number of States elected to use their share of this fund to strengthen their consultative services to nursing homes. Altogether, 75 percent of this fund has gone into chronic disease and health of the aging programs.

Other units of the Department have also taken measures to strengthen their service component. The Bureau of Old-Age and Survivors Insurance, for example, has recently established a welfare branch to help its field staff give better service to OASI beneficiaries who consult them about nursing homes and other personal problems. Recent public assistance legislation encourages welfare agencies to extend their social services to older persons, a significant step because social problems are quite as important as medical problems. The well-balanced nursing home program makes provision for dealing with both.

Goal 6. I hope this partial review of Federal programs will prove of some value to you in achieving your final goal of setting guidelines for future action. For any Federal effort to be meaningful, it must be backed by local action. Every type of Federal aid, to be of

real value, must evolve from firm roots in local soil; otherwise you may have paper progress, token action, but you will not really change the lives and outlook of the rapidly growing millions of the very old.

This First National Conference on Nursing Homes and Homes for the Aged will indeed become historic if it marks the beginning of a concerted drive to give our chronically ill and aged the kind of care that each of us would hope to have when it comes our time to enter into that final stage of life.

The Heart of the Matter

In a certain nursing home lives a little old lady, aged 90 years, a former school teacher. She is happy, active, comfortable, busy with crossword puzzles, books, and newspapers. She takes a daily walk around the block with the aid of her aluminum walker and watches the world go by from her cheerful front-room window.

A year ago, she was alone in the world, living in a house that had been her home for nearly 50 years. When a severe stroke crippled her, she was living in squalor, helpless in an unheated room. The postman missed her usual greeting one day, and getting no response to his knock, he summoned the police. After a few weeks in the hospital, she was removed to a nursing home.

There, with skilled care under a physician's supervision, she was restored to her present state of self-care, better health, comfort, and good spirits. Her pension and funds from the sale of her house assure her good care in the nursing home as long as she lives. Her remaining years will be far happier there than in any other setting.

She (with some 300,000 others in nursing homes and homes for the aged) is the focal point of your deliberations. Never lose sight of her, or her counterpart in some home known to you.

It is not easy to keep focused on the human factor. We deal with scores of impersonal

This summary is based on remarks by Leroy E. Burney, M.D., Surgeon General of the Public Health Service.

factors. Physicians may tend to think of diseases and diagnoses, administrators of programs and procedures, nurses of medications and supervisory problems, social workers of caseloads and therapeutic interviews.

But if we think exclusively of our own little specialties, we do so at the peril of the people we serve. For although each of us makes a necessary contribution, no one has all the knowledge, the skills, and the resources to place and maintain this elderly, retired school teacher in her present happy state.

Nor can we think exclusively of our particular zones of responsibility, whether it is national, State, or local. What is done or not done in each zone, in the national agency, the State, the community, and the nursing home affects in some degree all other zones. And this in turn affects for better or worse the people in nursing homes and homes for the aged. We who have any kind or degree of responsibility for the well-being of aged people cannot afford to let a colleague's efforts go unmarked with respect, his successes without rejoicing, nor his failures without prompt help.

Kaleidoscope of Health Services

There is no ideal pattern for nursing homes and homes for the aged in the kaleidoscope of health services for older people. The health services that older people require, like the bits of colored glass in a kaleidoscope, can be arranged in an endless variety of harmonious, effective patterns to suit the circumstances of any individual, any family, any community, or any State. The nursing home is just one piece, and its place in the pattern depends on the availability and quality of other health services for the aged.

This is a vast kaleidoscope, and we must keep our eyes on single bits of this pattern which concern this conference. We must seek a common vantage point from which we can describe the place of the homes and their quality in practical terms as realistic goals for every institution, community, State, and national organization.

Facilities and services that permit better care of older people are at the center of the larger

problems of aging. This lack keeps tens of thousands of older patients in general hospitals when they no longer need full hospital services. The lack of enough high-quality nursing homes and homes for the aged, or their equivalent, places persistent, exorbitant demands upon many communities for additional general hospital beds and drives up the costs of hospital care. The lack of high-quality institutions to serve the aging population thus denies good hospital care to thousands.

According to the first estimates of the U. S. National Health Survey, about 1,800,000 men and women over 65 years are unable to carry on their normal family and vocational activities because of chronic conditions. I do not imply that all of these should be in nursing homes or homes for the aged. But among them are many whose families cannot afford skilled care at home, many who are eking out a lonely, marginal existence, and many whose illness contributes to dependency because an employed member of the family must give up a job to care for an invalid. We have reason to be disturbed about the dollar price of our neglect of health services for the aged; it touches everyone's pocketbook.

Personal Concern

More important, we care about people. The past 20 years have dynamically changed the whole fabric of our society. But another sort of change, hard to define and springing in part from these dynamic processes, is becoming widespread. It might be called the depersonalization of society. Industrial automation and its counterparts in family life have removed large segments of the population from direct participation in basic communal activities. Decisions affecting the entire population are made by a relatively few people far from the local community. As cities absorb neighboring rural areas, distances from residential areas to the center of community decision increase. The migration to the suburbs is depriving the central city of much of the personal concern of its leadership. Not only in metropolitan areas but in the burgeoning smaller cities communi-

functions tend to become concentrated in the hands of a few.

This aspect of depersonalization should be a

continuous warning light to the health and welfare professions. In making community decisions leaders in these fields should be severely

Nursing Home

FACTS

TYPES OF HOMES

Proprietary. Operated under private, commercial ownership.

Public. Operated under State or local governmental auspices.

Voluntary. Operated under private, nonprofit auspices, such as church and other groups.

Skilled nursing. Provides as its primary function skilled nursing care, including procedures which require technical nursing skill beyond that of the ordinary untrained person.

Personal care (with skilled nursing). Provides some skilled nursing care, but only as an adjunct to its primary type of services.

Personal care. Provides such personal services as help in walking, getting in and out of bed, bathing, dressing, and feeding and supervision of self-administered medications.

Shelter. Provides room, board, and minimum services of a domiciliary nature such as laundry, personal courtesies, and occasional help with tasks such as shopping and correspondence.

THEIR NUMBERS

There are an estimated 25,000 nursing homes and homes for the aged in the United States.

They contain 450,000 beds, 180,000 in skilled nursing homes, and 80,000 in homes that provide some skilled care.

Ninety-one percent of the nursing homes are privately owned; three percent are publicly owned. The publicly owned homes have 15 percent of the beds, an average of 69 each; privately owned homes average 18 beds each.

Nursing homes are licensed by every State and Territory except Puerto Rico and the Virgin Islands; only Puerto Rico, the Virgin Islands, and South Carolina do not license homes for the aged. State agencies responsible for licensure programs are:

Type of agency	Nursing homes	Homes for the aged
State and Territorial health departments	42	34
State welfare departments	6	14
Other State agencies	3	2
None	2	3
Total	53	53

The demand for nursing homes is growing. At present 15 million Americans are more than 65 years of age, and by 1975, there will be 19 million. The control of infection, higher standards of living, and improved medical and hospital care are contributing to the longevity and growth of the population of oldsters.

THEIR RESIDENTS

Nursing home residents have an average age of 80 years; two-thirds of them are more than 75 years old. Two-thirds of them are women. Two-thirds have some circulatory disorder. Less than half can walk alone. About one-third are incontinent. More than half have periods when they are disoriented.

Their care costs an average of \$150 monthly. Public funds pay for the care of 50 percent of nursing home residents, and public assistance payments range from \$55 to \$155 per month.

These definitions and data were obtained from Public Health Monograph No. 46, *Nursing Homes, Their Patients and Their Care*, by Jerry Solon, Dean W. Roberts, Dean E. Krueger, and Anna Mae Baney, 1957.

self-critical lest we fall into the delusion that we are the community.

A major contribution of this conference can be to lift the deadening hand of depersonalization from planning and programs for the aging throughout our country. In doing so we would release the most powerful force that mankind has developed, the force of human affection and personal concern.

To do this, we need to touch base with the realities of the problems we hope to solve; to draw upon the experience of the frontline workers in our midst.

I come back to the little old lady in the nursing home. By keeping her in the center of our thinking, we find that the patient is often the first obstacle. Don't think she wears a halo. A person so resistant to change is not easy to help.

Many older people seem to withdraw progressively from the world around them. Their perception of themselves and others and their responses seem to grow less acute. When illness comes, the benefits of medical, psychological, and social treatment are more difficult to achieve. The family may also be an obstacle to better care and better health of an older person.

The community, however, is the greatest obstacle to better care and better health of the aging in these homes. By its collective attitudes and its resistance to change, the community places these institutions in the same withdrawn situation that characterizes so many of their residents. The community has allowed the remarkable scientific and technical advances of this century to bypass nursing homes and homes for the aged.

Deeply rooted in the community consciousness is the age-old dread of institutions. In the 19th century the hospital, as well as the nursing home, the county farm, or the old folks home, was a place for the sick poor to go to, and die. Advances in medicine, psychiatry, sociology, architecture, equipment, and personal services have revolutionized the community general hospital and made it a place where all classes go, and live. These advances are applicable to the nursing home and the home for aged, as many existing institutions have demonstrated.

Our main task is to find ways that will make all nursing homes and homes for the aged places for all classes to go and live.

State and Local Progress

Despite overwhelming handicaps, the State and local official agencies that license nursing homes and homes for the aged are making great progress. But there is much more progress to be made. Moreover the official agencies alone cannot improve the operation and the quality of patient care in these institutions.

Primary responsibility for the licensure of nursing homes and homes for the aged rests with the State health department in most States. Moreover the health departments are usually consulted in the States where some other department handles licensure. Within the State health departments, however, administrative patterns for licensure vary. But the majority of the departments have the same overall program director for both licensure and Hill-Burton programs. Usually the licensure unit itself is a small section within a division of the health department. It calls on other parts of the State health department for such services as public health nursing, nutrition, environmental health and safety, and chronic disease.

The licensure of hospitals and the licensure of nursing homes and homes for the aged are handled by separate units in most States, although an increasing number of States are combining their functions in one division.

State agencies are delegating more and more functions to local agencies when the local unit can handle them. States with strong local health departments find that decentralization is effective and that activities relating to the homes can be integrated into regular public health programs.

Other States hold that decentralization to the regional level is best, and some carry on all activities from the State level. Others are still

This summary is based on a paper presented by Bruce Underwood, M.D., consultant in nursing homes, Chronic Disease Program, Public Health Service.

experimenting and trying out various plans. Some understaffed local health departments do not have time to give to programs for the homes. However, it is my impression that whenever local health departments have a major role in these programs, progress is greater. The picture is similar in the States where welfare departments have the licensure function.

There is wide variation in the types of personnel who actually do the inspections and consultations and carry on the programs. The background of these people may be primarily environmental health, architecture, engineering, medicine, nursing, or a combination thereof. Few State licensure agencies have adequate staffs. Consultation services available from or through the agencies are usually meager.

Inspection procedures also vary. In one State, 7 to 9 inspectors from separate agencies must visit the nursing home before a license is issued. In most, one person inspects for the official licensure agency and another for the official fire safety agency. The inspecting agencies usually work well together and with interested voluntary and professional groups, but in a few States there is little cooperation.

Educational Approach

Perhaps the most important trend among the official agencies is the use of the educational approach rather than the big stick of law enforcement. In one county with long experience in licensing, the official inspectors or consultants have good relationships with the homes. Persons who want to open homes are helped if they can meet the standards, discouraged if they cannot. Homes are approached with these questions: How can we help you? What can we do for you? What are your problems? How can they be met?

This county once had a number of homes that didn't comply with the standards. At informal hearings with the administrators of these homes, laws and standards were not emphasized. Rather patients' needs were stressed, a list of necessary items were agreed upon, and a timetable and priorities were established for the most urgent needs. In this way, the homes, agencies, professions, voluntary agencies, and the nursing home administrators came to under-

stand, support, and cooperate with each other. Together they received the all-important backing of public opinion and public understanding as well as the support of appropriation agencies.

This educational approach is being used increasingly all over the Nation. Where it prevails, the State nursing home associations usually want higher standards, stricter enforcement, and more consultative assistance than the official agency can give. In some areas cooperation is so close that official personnel are difficult to distinguish from those of the voluntary agency. Statewide and regional seminars and institutes are jointly planned and conducted.

Signs of the Future

Nursing home laws and regulations are being revised and standards are being raised all over the Nation. The Public Health Service is assisting official agencies by providing consultation of various kinds and making available instructive handbooks. Various laws and regulations on nursing homes and homes for the aged are being compiled. Also under way is the development of definitions and principles for the States to use as a guide for their nursing home laws and regulations.

Some new, exciting developments are indications of the future. In Peoria, Ill., under a project of the Illinois Public Aid Commission, workers have been trained and are visiting nursing homes to teach aides physical and occupational therapy and rehabilitation techniques.

The outlook of the staff in the homes is changing. One of the attendants in one of these nursing homes was asked, "What do you think of this program?" She answered, "It makes me feel good down in my heart." The administrator of that home said, "Our home will never be the same. People are being rehabilitated and returned to self-help at home or in a foster home at the rate of five or six a month."

Efforts are being made in at least one State to set up accreditation programs for nursing homes in addition to licensure. Others are studying operating costs and personnel time. Some States are experimenting with increased payments to nursing homes to employ physical

self-critical lest we fall into the delusion that we are the community.

A major contribution of this conference can be to lift the deadening hand of depersonalization from planning and programs for the aging throughout our country. In doing so we would release the most powerful force that mankind has developed, the force of human affection and personal concern.

To do this, we need to touch base with the realities of the problems we hope to solve; to draw upon the experience of the frontline workers in our midst.

I come back to the little old lady in the nursing home. By keeping her in the center of our thinking, we find that the patient is often the first obstacle. Don't think she wears a halo. A person so resistant to change is not easy to help.

Many older people seem to withdraw progressively from the world around them. Their perception of themselves and others and their responses seem to grow less acute. When illness comes, the benefits of medical, psychological, and social treatment are more difficult to achieve. The family may also be an obstacle to better care and better health of an older person.

The community, however, is the greatest obstacle to better care and better health of the aging in these homes. By its collective attitudes and its resistance to change, the community places these institutions in the same withdrawn situation that characterizes so many of their residents. The community has allowed the remarkable scientific and technical advances of this century to bypass nursing homes and homes for the aged.

Deeply rooted in the community consciousness is the age-old dread of institutions. In the 19th century the hospital, as well as the nursing home, the county farm, or the old folks home, was a place for the sick poor to go to, and die. Advances in medicine, psychiatry, sociology, architecture, equipment, and personal services have revolutionized the community general hospital and made it a place where all classes go, and live. These advances are applicable to the nursing home and the home for aged, as many existing institutions have demonstrated.

Our main task is to find ways that will make all nursing homes and homes for the aged places for all classes to go and live.

State and Local Progress

Despite overwhelming handicaps, the State and local official agencies that license nursing homes and homes for the aged are making great progress. But there is much more progress to be made. Moreover the official agencies alone cannot improve the operation and the quality of patient care in these institutions.

Primary responsibility for the licensure of nursing homes and homes for the aged rests with the State health department in most States. Moreover the health departments are usually consulted in the States where some other department handles licensure. Within the State health departments, however, administrative patterns for licensure vary. But the majority of the departments have the same overall program director for both licensure and Hill-Burton programs. Usually the licensure unit itself is a small section within a division of the health department. It calls on other parts of the State health department for such services as public health nursing, nutrition, environmental health and safety, and chronic disease.

The licensure of hospitals and the licensure of nursing homes and homes for the aged are handled by separate units in most States, although an increasing number of States are combining their functions in one division.

State agencies are delegating more and more functions to local agencies when the local unit can handle them. States with strong local health departments find that decentralization is effective and that activities relating to the homes can be integrated into regular public health programs.

Other States hold that decentralization to the regional level is best, and some carry on all activities from the State level. Others are still

This summary is based on a paper presented by Bruce Underwood, M.D., consultant in nursing homes, Chronic Disease Program, Public Health Service.

plans should include arrangements for ready transfer of patients into the hospital and back again as their needs dictate, with full exchange of medical and related information. Arrangements may also be made for bringing the benefit of the hospital's resources to the patient while he is in the home, through use of the hospital's laboratory, radiological, and other direct services, and through consultative services to the patients and the staff by the medical, dental, nursing, dietary, physical therapy, social, and other staffs of the hospital.

7. There is a trend toward establishment of nursing homes under the jurisdiction of hospitals. This is one among many other arrangements for achieving closer relationships between nursing homes and hospitals. This trend should be encouraged, particularly for the benefit of certain types of patients for whom close and continuing medical supervision is most essential.

8. Older people who are ill have changing needs, ranging from full hospital care to assistance in personal care. For those who are not in need of hospital services, the remaining range of services may be provided within a single facility or in several different types of facilities. It is the community's responsibility to assure the availability of

these services and to make possible the ready movement of patients among facilities according to their needs.

9. Voluntary classification and accreditation of nursing homes and homes for the aged have the potential for upgrading standards of care beyond minimum acceptable requirements of licensing programs. It is important that appropriate mechanisms for such an accrediting and classification process be developed.

10. The beginning efforts toward correcting the lack of training of health personnel in the problems of care of chronically ill and aged persons are commended. Extension of undergraduate and graduate education programs in this direction is strongly urged for all professions contributing to care. Nursing homes and homes for the aged should be utilized in such educational programs as appropriate clinical teaching facilities.

11. There is a great need for research and investigation into the many complex problems associated with nursing homes and homes for the aged. Emphasis should be given to expanded programs of study and experimentation directed toward improvement of administration, to provision of health, social, and related services, and to financing of these services and facilities.

ministrators of nursing homes and homes for the aged concerning their programing of medical care.

4. For maximum benefit to patients in nursing homes and homes for the aged, it is recommended that:

- Each patient have his own personal physician and be under continuous medical supervision.

- Every patient have a medical and social evaluation prior to or at the time of admission to establish a specific plan for care and that this evaluation be made a part of the patient's record in the home.

- Every home have an organized plan for the medical care of its patients.

- The frequency of physician visits rests with the personal physician and should be based on the needs of the particular patient.

5. It is recommended that general hospitals and nursing homes cooperate in the development of integrated programs for care of long-term patients.

6. It is recommended that there be further exploration of the development of nursing home facilities as integral units of general hospitals.

7. Colleges of nursing should be encouraged to develop regional conferences on nursing administration in nursing homes and homes for the aged in the various States in cooperation with nursing home associations and State health and welfare departments similar to the pilot project conducted in Pennsylvania, December 9-13, 1957.

8. Nursing services in skilled nursing homes should be under the supervision of a registered professional nurse.

9. Personal care home groups should, as a minimum requirement, have their nursing care supervised by a trained, licensed practical nurse.

10. It is recommended that curriculums in nursing education be enriched to include clinical practice in chronic illness and administrative practice in chronic illness facilities.

11. Since personnel policies have a direct effect on recruitment and retention of qualified personnel, it is recommended that clear, written

Selected Professional Services

1. In order to insure proper placement of the nursing home patient in the facility best suited to his needs, it is recommended that a system of classifying patients be developed which considers diagnosis, type and degree of disability, potentialities for rehabilitation, and medical, nursing as well as other professional service requirements. A beginning has been made in several localities toward developing such a classification, but it is felt that further research is required to refine, improve, and test such a classification system.

2. Every home should have some organized plan for medical supervision in keeping with its size and needs. It is recommended that

every nursing home operator select at least one physician to act as principal medical adviser to advise on medical administrative problems, review the home's plan for medical care, and handle emergencies if the patient's personal physician is not available.

3. The adequacy and effectiveness of medical supervision depend in part upon the relationship that exists between the home operator and the local physicians. Recognizing the need for continued improvement of this relationship, it is recommended that the American Medical Association Committee on Aging continue its efforts to bring about the formation of State and local committees on aging to advise ad-

therapists and occupational therapists to return people to self-help whenever possible. They are finding this program to be more economical in the long run, to say nothing of the humane factors involved. There are many other new developments and activities taking place in our Nation.

The philosophy behind these omens of the

future has been expressed by Dr. Albert L. Chapman, Division of Special Health Services, Public Health Service, in these words, "The hallmark of civilization is a voluntary commitment of time and money to make sure that oldsters, youngsters, and the infirm are not denied whatever benefits and privileges a humane society can endow them with."

Conference Recommendations

General Policy Questions

1. Nursing homes and homes for the aged are and should continue to be administered under public, voluntary, and proprietary auspices. All have a part to play in providing facilities of good quality. In any particular instance, the most desirable sponsor of a facility from the community's point of view is that one which will provide the best quality of care economically.

2. To clarify the functions of nursing homes and homes for the aged, the following fourfold classification of services is recommended. Each successive category encompasses the preceding category and goes beyond to the extent indicated. Homes, whatever their names and auspices, may be characterized according to the level of services provided in these terms of classification.

Services

The descriptions only convey the essential differences among the categories. This should not detract from the necessary focus in each of the categories on the social, emotional, and spiritual needs of the residents as part of providing opportunity for a satisfactory total pattern of living.

Residential services. Encompasses housing, food services, and limited services of a domiciliary nature such as laundry, personal courtesies, occasional help with correspondence or shopping, and an occasional helping hand short of

routine provisions of "personal care."

Personal care. Includes such personal services as help in walking and getting in and out of bed, assistance with general bathing, help with dressing or feeding, preparation of special diet, supervision over medications which can be self-administered, and other types of personal assistance of this order.

Nursing care. Includes services in caring for the sick which require technical nursing skills.

Comprehensive services. Extends the types of care outlined above to emphasize, in addition, social and group-work services, auxiliary medical services and rehabilitation (including psychiatry, physical medicine, and occupational therapy). This multiplicity of services provides full opportunity for a rich, well-rounded living experience in its social and psychological aspects as well as medical and nursing aspects short of hospital care.

Facilities

Corresponding to this classification of services, the following terms are recommended as designations for understanding the type of home, whatever its given name. These types are the residential facility, personal care facility, nursing care facility, and the comprehensive services facility.

It should be recognized that any type of facility need not confine its services to its residents. It may also be open to persons living out-

side the facility who come in for a portion of the day to use its services.

3. Comprehensive planning at the local level should be done in developing new facilities, utilizing existing planning agencies where such exist, or creating a medium for this purpose. Community planning for new facilities should take into consideration the availability of services to assist in care of patients in their own homes.

4. For those persons who can and wish to be cared for in their own or family homes, this "natural" home usually provides the most desirable environment. To help maintain this environment, the community should make available enabling resources such as visiting nurse services, homemaker services, day centers, foster homes, meal-delivery services ("meals-on-wheels"), and so forth. For those persons in this category who are in financial need, the community should provide adequate financial assistance.

5. Government, through its public welfare programs, is in a position to influence the quality of nursing home care. By its frequently inadequate payments for public assistance recipients in nursing homes, government denies to many patients adequate care while it perpetuates the operation of homes at a sub-standard level. Government should provide payments for public assistance recipients in nursing homes in amounts sufficient to assure provision of adequate care.

6. The development of planned cooperative arrangements between hospitals and homes for the aged and nursing homes should be widely and energetically promoted. Such

cost and cultural demands of the patients and residents in the homes.

2. The food service in nursing homes and homes for the aged should meet the nutritional needs of the patients and residents through foods. Nutrient concentrates should be given only on the prescription of a physician.

3. Any processed foods served in nursing homes and homes for the aged should be processed by safe and approved methods.

4. The licensing agency should provide ways and means of making it possible for nursing home administrators to put into practice a food service which will meet the Recommended Dietary Allowances. This will involve information on selection and use of kinds and amounts of foods at varying cost levels and use of qualified personnel and/or authoritative materials. Some sources of personnel and materials are official and nonofficial health and welfare agencies at national, State, and local levels; colleges and universities with home economics departments; hospital dietitians and dietetic associations; and Federal, State, and local departments of agriculture and extension services.

5. At least 3 meals per day should be provided with not more than a 14-hour span between a substantial evening meal and breakfast.

6. Food should be prepared in ways that conserve the nutritive value, and it should be suitably cooked for the digestive capacity of the groups served. The food should be served in a manner that will be acceptable to the patients and residents.

7. Table service for the individual or group should be available to all those who can and will eat at a table. Table service should be provided in a manner that will best serve the interests of the patients.

8. Because of the therapeutic value of getting the patient up for meals wherever possible this practice should be followed, whether or not it would affect the classification of the patient or the rate charged.

9. The entire licensing staff of the regulatory agency should be familiar with the criteria for evaluating

the food service and the specific assistance for food service which may be provided to the operator of the home.

10. The licensing agency should assume responsibility for education and training in all phases of food service for all personnel in nursing homes and homes for the aged. Such education and training should include individual and group conferences, on-the-job training, and formal training. Qualified personnel from the following sources could be used: health and welfare agencies, home economics departments of colleges and universities, hospital dietary departments, and departments of vocational education. New and prospective employees in nursing homes and homes for the aged should be included in such programs.

11. Formal training of professional workers concerned with care

of patients and residents of nursing homes and homes for the aged should emphasize geriatrics and especially geriatric nutrition. Furthermore, this recommendation should be relayed to the appropriate organizations and groups responsible for its implementation.

12. Regulations should require that there be made available for review the menus as served, a record of kinds and amounts of food used for a given period of time, and the number of people served during this period.

13. A national project should be conducted to develop a cost accounting system specifically for nursing homes and homes for the aged.

14. Further studies of the nutritional requirements of the aged person in nursing homes and homes for the aged should be encouraged; this recommendation should be referred to properly equipped research laboratories.

Social and Related Services

1. It is recommended that as a basis for sound medical, social, and personal planning for the older individual, there be the recognition that he be enabled through coordinated community efforts and services to remain in his own home as long as this is consistent with his health and welfare.

2. It is recommended that ways be developed to provide information about services and resources to guide the aged and their families to the appropriate service or resource which may best meet their needs. These informational resources could be central referral services, brochures, booklets, and/or other media.

3. It is recommended that in the interest of mobilizing and making available all community resources for the evaluation of the older individual and his needs, emphasis should be placed on the importance of the development and coordination of consultative services at Federal, State, regional, or local levels.

4. It is recommended that the team approach be used in evaluating the individual's health, social, and other related needs, including the involvement of the older individual

and his family in order to do the best possible planning to meet his needs and those of his family.

5. It is recommended that in all applications for institutional placement, the total assessment of the older person's needs and the resources available to meet those needs, be required prior to actual placement in any institutional setting.

6. We recommend acceptance of the basic premise that persons living in institutions have a right to live as fully as possible within the limits of their abilities and within the limits imposed by the group setting. To achieve this end, full utilization of all social and related services of the community is essential.

7. We recommend continuous consultation on social and related services by both regulatory and other public and voluntary agencies to all institutional facilities for older people.

8. We recommend that professional schools include in their curriculums content material emphasizing the social and emotional needs of older people. Professional schools, colleges, universities, and other com-

personnel policies be developed by nursing homes and homes for the aged, including job descriptions, plans for orientation of new staff and provision for inservice education. It is suggested that the American Nursing Home Association give consideration to the development of suggested personnel policies for nursing homes.

12. It is recommended that appropriate groups undertake research projects in nursing homes and homes for the aged to develop criteria for classifying patients according to nursing needs, the levels of nursing personnel required to meet these needs, and the educational programs desirable for each type of personnel needed to provide these services.

13. State licensing agencies should include professional health consultation services for nursing homes and homes for the aged.

14. It is recommended that a study be made to determine the requirements of nursing homes and homes for the aged with relation to supply, availability, storage, dispensing, and supervision of administration of medications. This study should consider providing medications for acute, chronic, and maintenance needs with due regard for all legal and medical requirements.

15. Medication and its administration should be based on the plan of medical care for the patient and the level of nursing services available.

16. Comprehensive dental care has not been readily available to many residents of nursing homes, especially to those in smaller institutions. In most instances, dental treatment has been limited to emergency care for the relief of pain.

Therefore, to stimulate interest in oral health and to improve the quality and quantity of dental care in nursing homes, the following actions are recommended:

- Dental evaluation of patient on admission to be included in the patient record.

- A principal dentist and/or an advisory committee to nursing homes and homes for the aged should be appointed from the appropriate dental society.

- The dental staff of the community hospital or hospitals should organize a liaison committee with the administrators of nursing homes and homes for the aged for dental consultations and service.

- The dental division of the public health agencies should establish a consultant service to nursing homes and homes for the aged.

- The curriculum in dental schools should include instruction in problems of caring for the chronically ill and the aging.

- Research should be conducted to establish dental needs, necessary portable equipment, and appropriate treatment procedures.

- There should be representation of the dental profession on planning committees for nursing homes and homes for the aged.

17. It is recommended that refresher courses and inservice training on dietary service be provided to personnel responsible for inspection of nursing homes and homes for the aged.

18. It is recommended that to meet more adequately the individual needs of patients in nursing homes and homes for the aged, established community agencies jointly undertake a plan whereby specialized professional services in the community are made available to patients in these facilities. Such services might be made available by voluntary or public agencies or both. Services should include occupational, recreational, and physical therapy, and social, nutritional, X-ray, laboratory, pharmaceutical, and dental services. Specific patterns for providing these services will depend on the local situation.

19. It is recommended that central referral and counseling services for the chronically ill and the aged be developed on a community or regional basis with provision for outposts in surrounding local areas.

These services should be provided by skilled professional personnel.

20. Public assistance agencies with support and cooperation of professional and other interested groups should make the utmost effort, as part of their responsibility for providing care for indigent persons, to obtain public funds adequate to provide the recommended services.

These services should be furnished to all patients on the basis of their needs, without regard to the source of financial support or the type of ownership of the institution.

21. One objective of the nursing home is to promote optimal physical and emotional health and to restore and return to his community every individual who has a potential for such restoration. Therefore, it is recommended that:

- Efforts be made to develop within the nursing staff techniques and skills in counseling and in restorative services and to utilize these so that the patient will not remain bedridden unnecessarily.

- Nursing homes adopt a program of restorative care that can be accomplished through a combination of direct services by the staff or by personnel services provided by other community agencies and consultation services. Personnel used for such services should be individuals with recognized professional qualifications who function under specific medical directions.

- The therapist should be a graduate of a school approved by the American Medical Association's Council of Medical Education and Hospitals, and State licensed or registered, if required by the State.

- Those patients with severe disability and rehabilitation potential beyond the capacity of the nursing home should, when possible, be referred to a rehabilitation facility.

Nutrition and Food Service

1. The nutritional needs of persons in nursing homes and homes for the aged should be met in accordance with the National Research Council's current Recommended Dietary

Allowances adjusted for the population concerned.

It is recognized that these allowances may be met by many food combinations designed to meet the

grams of self-inspection of members' facilities, and

Whereas in facilities where unsatisfactory conditions are found to exist the several State associations do take appropriate action to have such conditions corrected and when this fails deny or revoke association membership, and

Whereas this program of self-inspection is most beneficial to the welfare of the patients as well as the financial success of the individual nursing home,

Therefore, State nursing home associations are commended for their programs of self-inspection and are urged to continue and strengthen their procedures for corrective action in the case of members who continue to willfully and flagrantly fail to carry out the objectives of good nursing care of the nursing home association.

9. Whereas it is the total care given to the nursing home patients which is of paramount importance to the nursing home operator, the general public, and the State and local agencies responsible for the inspection and licensure of nursing homes and nursing home operators, and

Whereas the development of a mutual understanding between the official agencies and the members of the nursing home industry for the ultimate attainment of an acceptable level of care in nursing homes and a better understanding of the problems involved in this rapidly increasing community responsibility, and

Whereas this goal would be attained more readily if the staff members and the directors of the official agencies responsible for the inspection and licensure of nursing homes were given an opportunity to approach their problems on a more definite and uniform basis, a better relationship could be established with the operators and agencies responsible for providing patient care,

Therefore, it is recommended that the Public Health Service undertake to establish regional meetings to train such public agency personnel, and to secure some financial aid for personnel selected to attend such training meetings.

10. Whereas nursing homes and homes for the aged have a real and vital concern with the process of aging, and

Whereas there is proposed a White House conference on aging,

Therefore, it is recommended to the U. S. Department of Health, Education, and Welfare, and to such other agencies as may participate in structuring a White House conference on aging, that the assistance of representatives of nursing homes and homes for the aged be actively sought in developing plans for the conference.

11. Whereas the thermal, acoustical, and illumination characteristics of environment have a direct bearing on the health and safety of the aged in both private and institutional homes, and

Whereas there exists today no recognized qualitative or quantitative criteria for the design of the opti-

mum environment for the aged, in terms of thermal, acoustical, and illumination factors,

Therefore, it is recommended that the Public Health Service foster the development of study and research programs leading to a better understanding of these important environmental factors and to the development of criteria which may serve as a basis for sound environmental design.

12. Whereas the proper care of the aged is a major and growing problem facing the United States today,

Therefore, it is recommended that the American Medical Association, American Hospital Association, American Nurses' Association, American Dietetic Association, American Nursing Home Association, and other groups interested in the total problem coordinate their efforts in order to bring about maximum benefits to our aging population.

Regulatory Agency Problems

1. This conference should endorse the action of the Association of State and Territorial Health Officers, November 2-8, 1957, which has formally requested the Public Health Service to collaborate with other groups having interest in the field of medical care facilities to establish classifications and definitions of such facilities.

2. The Public Health Service should be asked to develop a model law, rules, and regulations for nursing homes and homes for the aged.

3. The model law, rules, and regulations should provide that:

- each patient have his personal physician, a physician be available at all times for emergencies, and medical advice be available to the administrator;

- physical examinations be required within 48 hours of admission date and periodic examinations be made thereafter;

- the regulatory agency will specify the required records on a current basis, including identifying and socioeconomic information, records of physical examinations, and other continuing medical records.

4. The model licensure law

should include provision for an advisory committee to the regulatory agency composed of representative professional and interested groups, official and voluntary in the State concerned.

5. In drafting the model law, attention should be given to the human factors, for example, personal interest, dignity, and privacy in patient care.

6. The law, rules, and regulations should include initial and continuing evaluation of physical, mental, financial, educational, and moral qualifications of applicants for licensure to operate or manage nursing homes and homes for the aged.

7. It is recommended that in nursing homes sufficient personnel be on duty and awake at all times.

8. It is recommended that the Public Health Service undertake a study of the requirements for the staffing of nursing homes and homes for the aged.

9. It is recommended that the agency best qualified to provide the following functions should be the responsible regulatory agency: set standards for safety, environmental

munity agencies should be encouraged to offer institutes and other inservice training programs with similar content for institutional personnel and others working with older people.

9. We recommend that in every community there be a responsible group, such as the regulatory agency, council of social agencies, or other special group whose function it is to evaluate and interpret to the public the human values as well as the costs of social and related services. Evaluation and interpretation are

necessary if sufficient funds are to be secured and the best possible utilization of these funds is to be assured.

10. We recommend that studies be made by qualified individuals or agencies (voluntary or public) to develop minimum standards for the amount and types of social and related services required by the older person in a crisis and for his long-term requirements. These standards should be related to the size and type of community in which the older person lives.

Environmental Health and Safety

1. Whereas it is the consensus that fire protection in nursing homes for the aged is of paramount importance,

Therefore, it is recommended that the States adopt, as minimum requirements for life safety in these establishments, the current National Fire Protection Association Standards pertaining to nursing, convalescent, and old age homes, and that each State establish a deadline date for the adoption of these standards.

2. Whereas the importance and the use of automatic fire sprinkler systems in all nursing and rest homes and other structures housing the aged and infirm is recognized, and

Whereas it is especially important that such installations be made in rural locations not served by water mains, and

Whereas it is recognized that the installation of sprinkler systems and other safety to life measures present a problem of increasing operating costs, and

Whereas the majority of the patients housed in nursing homes are supported by the community and other public sources,

Therefore, it is recommended that the communities and their legal representatives recognize their responsibility to the aged and infirm to provide funds that will permit the installation of such equipment as necessary safety elements in the adequate housing of such patients.

3. Whereas there is not available

a compilation of all State and local laws, rules, regulations, and methods of enforcement in regard to nursing homes, and

Whereas such information would be of great value as a basis for discussions of standards and for assisting State and local groups in the development of standards,

Therefore, it is recommended that the work of the Public Health Service now being carried out in the compilation of such data be continued and extended to include laws detailing fire prevention and control, and that such a compilation be published and made available to interested groups.

4. Whereas innumerable active and prospective nursing home operators are acquiring or attempting to modify unsuitable facilities,

Therefore, it is recommended that all available means of publicity be utilized by all interested persons or organizations to acquaint the general public with the free consultation services offered by the individual State licensing agencies, and that a compilation of all such consultation services by any governmental or other agency be published for distribution by the U. S. Department of Health, Education, and Welfare.

5. Whereas the dissemination of information among the participants of this nursing home conference has proved most valuable in creating sympathetic understanding of common problems, which gives promise of practical approaches to the solu-

tion of some of these complex and difficult problems, and

Whereas this kind of transmission of information and development of understanding is most urgently needed at local levels where the facilities are being operated and where the laws are being applied,

Therefore, it is recommended that the Public Health Service continue and extend the sponsoring and development of regional conferences at the local level throughout the country, to which are invited personnel representing local groups similar to those participating in this conference and including agencies and organizations having an interest in the regulation of or services to nursing homes, as well as those agencies and organizations providing financial support for individuals cared for.

6. Whereas employees' fire safety training programs are required of hospitals for accreditation, and

Whereas the fire hazards in nursing homes and homes for the aged are generally similar to those existing in hospitals, and

Whereas the universal adoption of fire sprinkler systems is still in the future,

Therefore, it is recommended that this conference advocate that nursing homes and homes for the aged institute employee fire safety training programs.

7. Whereas accident prevention programs and specific procedures designed to avoid accidents in nursing homes and homes for the aged are restricted by a present lack of substantive information,

Therefore, it is recommended that the Public Health Service make known this general situation and advise qualified investigators that morbidity and mortality studies of nursing home accidents will be considered for National Institutes of Health research grants and, further, that State health departments, municipal health departments, medical schools, and schools of public health be specifically contacted in this regard.

8. Whereas several State associations of nursing home owners now operate desirable and effective pro-

ordinating services; reporting to the board, the public, and the clients; and budgeting.

2. All nursing homes and homes for the aged, whether nonprofit, proprietary, or public, should have a governing board or advisory committee. In some communities it may be more practical for several homes to utilize one committee.

3. Ways and means should be found for encouraging the conduct of active education programs for board and advisory committee members on their functions and responsibilities.

4. Every nursing home or home for the aged should have a medical adviser or medical advisory group. It should be the responsibility of the administrator to initiate the action for establishment of such advisory service, preferably utilizing a local general hospital. If there is no general hospital within easy access, liaison should be worked out with the medical profession through the county or State medical society.

5. A person who becomes an administrator of a nursing home or a home for the aged should be licensed to do so by a properly designated regulatory agency. Such a person should possess a personal motivation to provide or obtain suitable patient care, possess the customarily required moral qualities, and have the following minimum qualifications to merit a license:

- Graduation from an accredited high school or equivalent training.

- Successful completion of a prescribed course of training presented by a recognized educational agency. The content of the course may be planned in cooperation with pertinent professional organizations and approved by the regulatory agency. In any jurisdiction enacting legislation along this line it is expected that suitable training facilities be organized to make feasible the procurement of such training.

- A minimum of 6 months' professionally supervised experience in a recognized medical care facility

which would provide background and experience in institutional management, human relations, and ethical practices.

- For one currently functioning as an administrator of a nursing home and/or home for the aged it is further recommended that upon the establishment of a licensure program a grace period of not more than 3 years be extended as a reasonable period of time for such a person to acquire the additional training necessary to qualify for licensure. A specified number of years of appropriate experience could be accepted by the regulatory agency in lieu of this requirement.

- It is recommended that persons currently functioning as administrators of nursing homes or homes for the aged be immediately screened by a testing process designed to disqualify for such a position those who cannot demonstrate adequate ability to read and understand the regulations and literature pertinent to the operation of such institutions.

6. Every nursing home and home for the aged should have a home-like, cheerful, friendly, and hopeful atmosphere that will contribute to the promotion and preservation of the personal integrity of each individual. The home should make available and utilize those services necessary for the emotional, physical, social, and spiritual enrichment of the patient.

This would require properly trained personnel to provide: personal care including food, shelter, and personal hygiene; medical and nursing care, and rehabilitation and optimum health; social, emotional, and spiritual well-being.

Personnel should be selected on a full-time or a part-time volunteer basis to meet these needs. It is recognized that the size, location, and type of home would determine the variables in the staffing pattern of one home compared with another.

The administrator should have a knowledge of the necessary skills

and education, as well as the legal requirements for the successful performance of the services to be rendered.

In the selection and engagement of personnel, the administrator should give consideration to the individual applicant's physical, mental, and emotional qualifications for work with the resident "to help the patient to do as much as he can as well as he can as long as he can." He should try to instill in all of his staff a sense of dignity and worth as members of the team of the nursing home or home for the aged.

Personnel practices, methods, and procedures should be explained to staff members in the most effective way possible so that they will be apprised of their functions in the operation of the home. General policies under which the home operates should be written and available to all employees at all times.

7. The administrator of a nursing home and home for the aged should be responsible for determining the qualifications and suitability of each prospective employee for the job he is to perform.

8. Prospective employees should have a preplacement health examination.

9. Every administrator should provide opportunity for the growth and development of staff, professional and nonprofessional, through training either within or outside of the home. Such inservice training may be provided separately or in cooperation with each other by: nursing home associations, State welfare and health agencies, universities, professional organizations, hospitals and related institutions, and other voluntary agencies.

10. There should be uniformity of business and accounting practices in order to establish a basis for charges to patients and agencies purchasing patient care and for better planning and programing.

health, and patient care; carry out and coordinate inspections; give consultation and planning services; and furnish teaching.

10. It is recommended that a single agency have primary regulatory responsibility for all medical care facilities and homes for the aged.

11. It is recommended that there should be provision for the exchange of information between regulatory and other agencies which would enable all concerned to carry out their responsibilities.

12. It is recommended that State regulatory agencies arrange inter-agency meetings for workers within a State.

13. It is recommended that adequate funds be made available for research and demonstration projects by State and local agencies with monies furnished by Public Health Service, the States, or other agencies.

14. It is recommended that the appropriate body or bodies should: study staffing needs, qualitatively and quantitatively, of State regulatory agencies including full-time and borrowed services; survey the resources available for education and training of personnel; and prepare a plan to supply education and training not currently offered.

15. It is recommended that the appropriate body or bodies should: study training needs, qualitatively and quantitatively, for administrators of nursing homes and homes for the aged; survey the sources available for education and training of personnel; and prepare a plan to supply education and training not currently offered.

16. It is recommended that the Public Health Service be requested to collaborate with State agencies and other interested groups to collect statistical data at least annually, regarding nursing homes and homes for the aged.

17. It is recommended that there be regional meetings similar to the National Conference on Nursing Homes and Homes for the Aged.

18. It is recommended that regional meetings be held by the

Public Health Service, working with State agency personnel giving direct service of all kinds in the area of patient care.

19. It is recommended that the Public Health Service and the State agencies prepare additional guidance materials for dissemination to

administrators of nursing homes and homes for the aged.

20. It is recommended that the Public Health Service collect pertinent material developed by State regulatory agencies and all other agencies and disseminate such information.

Financing of Facilities and Services

1. There is need for Federal legislation to further encourage financing for the construction and renovation of nursing homes and homes for the aged, including a set of recommended construction standards for use by the financing agencies when such construction or renovation meets clearly demonstrated local needs. The need for such legislation is so urgent as to require prompt consideration by the appropriate executive and legislative sections of the Federal Government.

In view of the action already taken in certain States in providing funds for housing for older people, it is recommended that consideration be given to allocation of State funds on either a grant or loan basis for the construction of homes for the aged and nursing homes.

Since county and municipal tax funds have traditionally been a primary source of financing institutions for dependent local residents, the possibility of this source for additional financing should also be considered.

2. Since realistic payments cannot be intelligently negotiated without a sound basis of cost, it is recommended that modern accepted accounting methods be adopted in nursing homes and homes for the aged.

Local agencies should be encouraged to determine costs, based on modern accepted accounting methods, related to the kinds and quality of services that can be provided. Public assistance payments should

be established to provide a minimum commensurate with these established costs.

3. It is recommended that the Public Health Service collect and publish good cost data that are presently available concerning the operation of nursing homes and homes for the aged, separated by geographic area, and further subdivided to show various levels of service.

4. It is recommended that health insurers of all types should give earnest study and consideration to the further extension of health insurance to cover care in nursing homes and other institutions performing the functions of nursing homes. The prerequisites for such action should be establishment of the medical nature of the care and specific recommendation of the service by a physician either following hospitalization or otherwise. Consideration should also be given to continuation of existing health insurance policies, regardless of age or health condition of the insured. Welfare departments should continue the payment of health insurance premiums on behalf of people who have health insurance coverage at the time they are accepted for public assistance.

5. It is recommended that States be urged to take full advantage of Federal matching funds for medical care to defray cost of care of public assistance recipients in nursing homes and related institutions providing nursing care.

Administration of Homes

1. Every nursing home and home for the aged should have an administrator who is continuously responsible for the proper operation

of the home. His functions should include planning of objectives and services; organizing staff and facilities; directing, supervising, and co-

the TRANSFORMATION of NA NGOO

INTERNATIONAL MAIL POUCH

Na Ngoo is like tens of thousands of other villages in Thailand. Its 49 families own a few pigs, a scattering of scrubby chickens, and some buffaloes. They use bamboo, palm leaves, and rice straw from the surrounding country to build their houses. Those who can afford flooring timbers raise their houses on stilts, Thai fashion, always with an odd, never an even, number of steps to confuse evil spirits. Their household possessions are essential clothing, a few pots and pans, sleeping mats of woven grasses, and large clay jars for storing a day's water supply.

Despite the historic agricultural abundance of the country, the people of Na Ngoo, like millions of other farm families in Thailand, battle poor soil, a scarcity of water 7 or 8

months of the year, and the inaccessibility of markets for their rice crops. No more than \$30 or \$40 pass through their hands in a year of back-breaking toil. They cannot afford even a dollar or two for insecticides to prevent the loss of a crop or to build a tank for storing scarce drinking water.

Na Ngoo has no public facilities. Even its water hole, a stagnant pool during the dry season, is a kilometer away. The people send their children to a school nearly 2 kilometers distant because schooling is compulsory for the first four grades, but ignore the district health center, an equal distance away.

Smoking-Mortality Rate Among Veterans

A Public Health Service study among 198,926 United States veterans shows a significantly higher death rate among regular tobacco smokers than among nonsmokers. The first report on the continuing statistical survey was made July 8, 1958, by Dr. Harold F. Dorn, chief statistician for the National Institutes of Health, to the Seventh International Cancer Congress in London. Dr. Dorn is also chief of the Biometrics Branch in the Division of Research Services of the Institutes.

The survey generally supports findings of earlier studies which demonstrated a statistical relationship between death rates and smoking.

Death rates among the group of veterans who were United States Government Life Insurance policyholders were summarized for the period July 1954 to December 1956. The deaths were then related statistically to the smoking habits of the veterans. Clinical and laboratory research were not included in the study.

The initial report covers 7,382 deaths during the 2½-year period. Of these, 6,203 occurred in smokers and 1,179 in nonsmokers. The data was from persons who served in the Armed Forces between 1917 and 1940 and ranged in age from 30 to 90 years. The majority were between 50 and 70 years of age.

The report included the following points:

- The death rate from all causes of persons who used tobacco was 16 per 1,000, compared with 13.1 per 1,000 for persons who never smoked. Adjusted for differences in age distribution between the two groups, the death rate was 32 percent higher for smokers than for nonsmokers.

- Persons who regularly smoked only cigarettes had the highest death rate of all groups of smokers—58 percent greater than the death rate for nonsmokers.

- The lung-cancer rate for regular smokers of cigarettes only was about 10 times the death rate for nonsmokers.

- The death rate among regular cigarette smokers was closely related to the amount smoked. For example, the death rates of persons who smoked more than 40 cigarettes a day were much higher than those of persons who smoked fewer than 10 cigarettes a day.

- The death rate of persons who regularly smoked cigars or pipes, or both, was not significantly higher than that of nonsmokers. Only the heaviest users of cigar and pipe tobacco had an appreciably higher death rate from all causes than nonsmokers.

- Nearly two-thirds of the 6,203 deaths of tobacco users studied were attributed to diseases of the heart, blood vessels, and kidneys. The death rate from coronary heart disease was found to be 63 percent higher for regular cigarette-only smokers than for nonsmokers.

- Regular cigarette smokers who had stopped smoking cigarettes before the study began in 1954 had a lower mortality rate than those who continued to smoke. However, the rate was 30 percent higher than that of nonsmokers.

- Regular cigarette smokers also had higher death rates from certain respiratory diseases, such as bronchitis, pleurisy, and emphysema, from ulcers of the stomach and duodenum, and from cirrhosis of the liver.

- The death rate from coronary heart disease among regular users of cigarettes only is 63 percent higher than the rate for nonsmokers.

In addition to the use of tobacco, the continuing study will also explore possible statistical relationships between death rates and such environmental factors as occupations, work environments, and characteristics of the home communities.

Dr. Dorn's paper is entitled "Tobacco Consumption and Mortality from Cancer and Other Diseases." The study was made possible by the cooperation of the Veterans Administration.

Left: Na Ngoo's privies repudiated skeptics who said they would never be accepted. Right: Even the pigs are well scrubbed. Below: Sitting villager tells sanitarian Nai Chit Chivonge (left) that the new privies saved time which he used to make baskets to sell.

As one of the poorest communities in a fairly prosperous district, Na Ngoo was chosen to be one of a number of village pilot projects in health and sanitation. These projects were designed to find out if even the poorest villages could be induced to change old ways and if the individualistic Thai would work with others on community projects. This was the difficult task of Alexander A. Robertson, American sanitarian, when he began work in Na Ngoo in March 1957.

Three months later, the Public Health Office of the United States Operations Mission in Bangkok got a report from Robertson that 19 sanitary privies were installed in the village and 6 more were planned for completion the next month.

Curiosity drew us to Na Ngoo in early July. Three hours' travel from Bangkok over a fairly good, hard-surfaced road brought us to within a kilometer of Na Ngoo, but we had to make the rest of the way on foot over the rice paddy embankments. Our guides were Robertson, Dr. Khien Kraivichien, director of Cholburi Health Training Center, and Nai Chit Chivonge, sanitarian instructor.

Na Ngoo's health committee meets. Headman (1st left) and school teacher (3d right) are members. Below: Wife pours rice into milling machine.

district health center offered. He explained the advantages and problems of sanitation in the village and urged the people to talk it over. If they were interested, there would be another meeting.

A week later, the head of every family in the village gathered with Nai Chit, Nangsao Vimoon, Robertson, and Nai Thongkam. The villagers agreed that water was their big problem. The nearest supply was a kilometer away, often muddy, and at the height of the dry season, almost nonexistent. They needed more and cleaner water, and, if possible, close by. If the villagers were prepared to undertake a village sanitation program, the officials said, the health center would help them get a safe, dependable water supply and a pump.

But privies would have to come first, because the water cannot be kept clean and safe without them. And after the privies and the water supply, the village needed a general cleanup. All three steps were necessary to health, and all must be agreed to if they were to get help, the officials explained. Help would include cement and forms for making the privy slabs at cost. Payment, roughly a dollar per privy, would be required but not until after the next harvest. Any family that could not afford the cost all at once would be allowed several years to pay.

The heads of the 49 households, with some dissent, agreed to take the three steps and form a health committee.

A few days later, the men and women voted to elect the health committee members. The village was divided into 7 groups of 7 families each, and each group elected a member. The headman of the village and the local school teacher each won a place on the committee of 5 men and 2 women. If Na Ngoo had had a Buddhist temple, the abbot would have been given an honorary place on the committee, but the village is too small and too poor to support a temple.

The committee decided to start the cleanup immediately, while privy sites were selected.

They set Wan Phra, the Buddhist sabbath, as cleanup day, since it was the only day the people were not busy in their fields.

On the first cleanup day only five families worked. The second week seven more families joined them. Each week more and more people worked at the cleanup. Two families held out for almost 10 weeks, but finally they joined too. Whole families, working together, cleaned up their own compounds and then the public places. They dug the privy pits, built the housing over them, and learned to mold the slabs with the sanitarians' guidance. They built their health committee headquarters and dug the catchment and the wells.

We asked one man what part of the work was hardest. With a grin he replied, "Cleaning house," which to him meant cleaning the whole compound around his house as well. It was hardest because he did it every day after he came home, hot and tired from the fields. He didn't limit cleanup to Wan Phra.

He was eager to talk, so we questioned him. "Why is the program good for you?"

"I will make more money," he said.

"You mean save more money, don't you, by not getting sick and not having to spend money on medicines?"

"No. I will make more money. Not spend so much time looking for a place to relieve myself. Have more time to make things to sell."

Meanwhile, Nai Chit and the village committee were discussing something that seemed serious and important. The matter was finally settled with friendly smiling nods by these villagers who people said would never change their traditional easy, careless ways. On the way back to Bangkok we asked Nai Chit about it.

"The committee asked that another privy be built. A family who was sharing one with another would like to have its own. It will be built, of course."

—HARRY L. CARR and MRS. JAY S. BOHLE,
U. S. Operations Mission, Thailand

Left: The old water hole, a kilometer from the village, became a stagnant pool in the dry season. *Right:* Men, women, and children dug the rain catch basin and two wells, separated from the basin by a filter system, to give the village a constant, safe supply of water.

No one expected us, and most of the people were at work in the rice fields. But when we arrived the village looked as if it had been prepared for an inspection.

We hesitated to flick a cigarette ash in the cleanswept compounds. The houses were scrubbed and orderly, with wood neatly stacked. Animal pens were as clean as living rooms and the animals themselves fairly shone; even the hogs looked as if they were ready for a State fair. Buffaloes, customarily sheltered under the stilted houses, were penned under the shade trees.

The privies were the repudiation of skeptics who said they would never be accepted because privies infringe on the Thai's historic right to relieve himself when and where he pleases. Na Ngoo had 33 of them, although 25 would have sufficed with families sharing. Not only were they clean with daily scrubbing and covered with neatly built housing of rush and bamboo, but many had been decorated with fancy grass weaving.

The pride of the villagers was also mirrored in flower and vegetable gardens, growing where none had ever existed before. Women and girls were weaving fly covers to put over food dishes. One woman, who was milling rice, told us the food value of the grain was in the bran, not the white kernel.

Close by was the village's biggest achievement, its new water supply system. Everyone,

even the children, had worked on it. The headman donated a generous piece of land. On it they built a large catch basin and dug wells on either side. Now Na Ngoo's people would not have to walk a kilometer for their water, and their water was cleaner.

Under a huge tree in the center of the largest compound the village health committee built a shelter for its meetings. Adorning the building were colorful posters proclaiming, "Prevention is better than cure."

The health committee felt it was just starting its work. After the catch basin and wells would come a corral for the village buffaloes, to keep flies and manure a safe distance from the houses. Next they planned a community compost pit, a plentiful source of organic fertilizer for the tired land.

"How did it happen?" we asked. Na Ngoo was no hothouse project. Its changes had come from the heart and muscle of the people themselves.

Our three guides and Nangsao Vimoon Thongpoonsak, health educator, and Nai Thongkam Suwarnachitr, district sanitation officer, supplied the initial spark. One evening they pushed their jeep as close as possible to the village and strung a long electric cable from the jeep's generator. They showed an entertaining motion picture and a film on sanitation. Then Dr. Khien talked to the audience, everyone in Na Ngoo, about the services the

Part two of a series, this report describes microscopic findings in bones from persons exposed to 1.0 to 4.0 ppm fluoride in comparison with a series of controls. The study discloses no pathological condition that could be attributed to fluoride ingestion.

Pathological studies in man

after prolonged ingestion of fluoride in drinking water

**E. F. GEEVER, M.D., N. C. LEONE, M.D.,
P. GEISER, M.S., and J. E. LIEBERMAN, M.A.**

PUBLIC HEALTH programs to prevent dental caries by artificial fluoridation of drinking water have always considered the possibility of cumulative toxic effects. The present studies were instituted to determine whether pathological changes could be correlated with prolonged ingestion of fluoride-bearing water.

In an earlier publication we reported the necropsy findings in persons who had lived in a community with a fluoride level of 2.5 ppm (1). This is $2\frac{1}{2}$ times the level recommended for prevention of dental caries. Since necropsies do not routinely include microscopic examination of bones, a separate study of this phase of the question was undertaken. Persons com-

ing to necropsy who had lived in communities with 1.0 to 4.0 ppm fluoride, naturally occurring or added, in the drinking water were the subjects.

Material and Method

Necropsies were performed in Grand Rapids, Mich. (1 ppm), Colorado Springs, Colo. (2.5 ppm), Amarillo, Tex. (2.8 ppm), and Lubbock, Tex. (4.0 ppm). Bone specimens were obtained through the cooperation of local pathologists: Dr. Joseph Mann and Dr. Harold Bowman of Grand Rapids, Dr. Morgan Berthrong and Dr. Raoul Ulrich of Colorado Springs, Dr. Marie Shaw of Lubbock, and Dr. John Denko and Dr. C. P. Churchill of Amarillo. The series consisted of 37 persons who had resided for 10 years or more in the above communities. The majority, 24, were residents of Colorado Springs; they provided 65 bones for the study. The ages of the subjects, 17 men and 20 women, ranged from 36 through 90 years.

Dr. Geever is pathology consultant, Dr. Leone is chief of medical investigations, and Miss Geiser is a nurse officer, National Institute of Dental Research, Public Health Service, Bethesda, Md. Mr. Lieberman is a mathematical statistician, Biometrics Branch, Division of Research Services, National Institutes of Health.

Medical Care Responsibilities

Joint letter by the Surgeon General and Commissioner of Social Security to State and Territorial Health Officers and State Directors of Public Welfare, June 26, 1958

The fields of health and welfare administration offer many opportunities for joint action which can be mutually beneficial to the responsible agencies and result in improved services to the public. These opportunities have existed for years and in some States and communities have received considerable attention. Recent developments, however, have greatly expanded the opportunities for a concerted attack on the prevention and reduction of economic dependency due to illness. These developments accentuate the need for the closest possible working relationships between health and welfare agencies at all levels of government. Anything short of this aim is costly, both in terms of taxpayers' dollars and human well-being.

This joint letter is intended to focus on the growing need and to encourage mutual consideration of program objectives, plans, and resources by State health and welfare officials.

That illness is a major contributing factor to economic dependency and that low income breeds health problems are well-known facts. Public health departments have a traditional responsibility to provide and promote communitywide health services, such as immunization, public health nursing, and casefinding programs, nutrition and health education services. Many health departments have traditional responsibilities in regard to the medically indigent which sometimes involve diagnostic and treatment services. Special arrangements to ensure the fullest possible coverage of public welfare clients in all types of health

programs should result in improved health and decreased dependency for this population group.

Provision of or payment for medical care services for public welfare clients is commonly a responsibility of public welfare agencies. Public health agencies have much to contribute to the successful operation of such services. This assistance can take the form of ensuring that welfare clients receive the direct services of the public health agency, such as services for crippled children or for tuberculosis control. In other instances, the assistance may be through professional consultation in the establishment of standards and procedures for making medical care available to the welfare client. In some States it might be desirable for the welfare department to contract with the health department to administer the medical care aspects of the public welfare program.

Obviously, the arrangements will depend upon the varying legal and operational potentialities in the States. Again, however, joint consideration of the problems is imperative to effective and efficient working relationships. This is particularly important when public welfare agencies are contemplating new or additional medical care responsibilities.

We all know that family finances and the ability and willingness of a family to seek to correct health defects are closely related. With increased emphasis on chronic disease programs and health services for older persons, the problems of economic security are becoming ever more apparent as major considerations affecting the success of public health programs.

Public welfare agencies, with their

wide experience in administering financial assistance and welfare services related to the particular needs of the individual, can be of real help to health departments in problems of this kind. The welfare department can identify health needs of recipients and assist them to fully utilize public health facilities. Similarly, provision of social services and financial assistance to persons whose need is recognized by medical social workers and other staff of the health department frequently depends upon the resources and staff of the welfare department. Such interagency relationships cannot be maintained effectively unless each agency is fully informed on the programs and resources of the other.

These examples of mutual interest areas between health and welfare agencies could be multiplied many times. The most useful identification of such areas, however, is in relation to the program objectives and resources of an individual State and as a first step in the development of interagency planning.

We are confident that increased attention to opportunities for interagency cooperation will result in better health and welfare services to the public and will enable both agencies to carry out more effectively their respective legal responsibilities.

The full resources of the Public Health Service and the Social Security Administration are prepared to provide technical assistance and consultation at your request to assist in accomplishing these goals.

L. E. BURNEX
Surgeon General

C. I. SCHOTTLAND
Commissioner of Social Security

Figure 2. Active osteoclasia and fibrosis, periosteum and cortex of lumbar vertebra, 105X, 59-year-old man, control series.

new bone pushed up the periosteum in a trabecular pattern. Sometimes foci of bone were found in the parosteal tissue with no apparent connection to the subjacent bony cortex.

Irregularity in contour in some fields was due to old or active periosteal osteoclasia (figs. 1 and 2). Sometimes gaps were visible in the bone where blood vessels entered and the periosteum appeared to be the only barrier between the marrow and adjacent marginal tissue, particularly in the sections of vertebrae. The majority of the frayed or fuzzy papillary projections of bone and basophilic material appeared to be old and unaccompanied by cellular proliferation. However, small strips or foci of bright, eosinophilic, new and incompletely calcified bone (osteoid) could be observed also. Often cuboidal or columnar osteoblasts were seen nearby.

Surface irregularity was frequently found near the sites of tendon insertion in the sections of iliac crest in both groups. Often it was accompanied by cartilaginous changes and irregular basophilic staining presumably due to calcification (fig. 3). Irregularity due to extension of cartilaginous and basophilic stained material along the front periosteal surface away from the intervertebral joint and toward

the midlevel of the vertebral body was often seen.

The criteria used in grading excessive bone or calcium deposition were based on the maximum degree of projection from adjacent surfaces as measured by an ocular micrometer, the maximum foci per standard low-power microscopic field, the number of fields affected, and the presence of extraperiosteal bone or basophilic stained foci independent of the adjacent cortex. Bones from the fluoride and control groups were examined alternately.

Irregularity in periosteal contour due to excessive bone or calcium deposition, or both, was found in 48 of a total of 94 satisfactory bone sections in 25 of the 33 controls (table 1). Similar changes were present in 35 of a total of 99 satisfactory bone sections in 24 of 37 fluoride-exposed persons. Focal, nonspecific inflammation was found in 3 bones in 3 controls and in 2 bones in 2 of the fluoride group.

Active osteoclasia was found not infrequently with 1 or 2 osteoclasts recognizable in the margins of typical Howship's lacunae. Arbitrary criteria were set up to evaluate increased activity. Since the tissue sections were only approximately equal in size, quantitation could also be only approximate. Grading was started at +, for a mild, or slight, increase based on

Figure 3. Parosteal and periosteal cartilaginous changes, iliac crest, 35X, 73-year-old woman, control series.

For comparison with the fluoride series, 33 persons, 24 men and 9 women, who had resided in essentially nonfluoride (less than 0.5 ppm) communities served as controls. They ranged in age from 21 through 87 years.

Most of the persons in both series died suddenly. The most common causes of death were trauma, coronary heart disease, and cerebral vascular accidents. Those with chronic illness and diseases known to affect bone structure were excluded. Thus, there were none with primary or metastatic bone cancer, long-standing cancer of other organs, or renal or parathyroid disease.

In most cases three bones were selected for the microscopic studies: the body of a lumbar vertebra, a portion of iliac crest, and the sixth rib. In addition, the lumbar intervertebral body joints were examined for possible changes in articular cartilage. Less often, the sternum was also studied. A few bone or joint specimens proved unsatisfactory for some phase of the study, with the result that the totals vary.

The bones were fixed in 10 percent formalin and forwarded to the National Institute of Dental Research. Decalcification was carried out using a 5-percent-formic-acid method. Paraffin embedding and sectioning were performed and hematoxylin and eosin stains were applied, according to routine procedures.

Fluoride analyses of most of the specimens in both these series (plus a few other specimens) were performed independently. The results are reported in a separate article, by Zipkin and colleagues, on pages 732-740 of this issue.

Parosteal and Marginal Tissue

Parosteal and marginal tissue consisted of laminated or loose collagenous elements often merging with and indistinguishable from periosteum. Striated muscle fibers, fat, blood vessels, lymph nodules, nerve trunks, or nerve ganglia were sometimes observed. In the sections of vertebra, the longitudinal ligaments were often included.

Focal, nonspecific, chronic inflammatory reactions were found in the marginal tissues of 4 bones from 3 persons in the control group. These foci were found adjacent to a lumbar

vertebra in 3 bones and near the sternum in 1. Focal swelling and necrosis of striated muscle fibers were found in another control, a 59-year-old woman who died of rheumatic heart disease. The changes, found near lumbar vertebrae were not accompanied by inflammatory reaction.

In the fluoride-exposed group, inflammatory change was observed in tissues of only one person. It consisted of a fairly severe subacute nonspecific parostitis of the rib. In both the fluoride and the control groups small marrow foci were seen occasionally in periosteal and parosteal tissue of the vertebrae. These foci were undoubtedly related to the marrow of the vertebral body.

Periosteum

The periosteal surface was often irregular, microscopically, in both series. The irregularity in itself followed no consistent pattern. Sometimes slender, frayed or fuzzy papillary projections of bone and basophilic material, presumably calcium, were seen. Occasionally, smooth deposits of bone bulged up over wider areas under the periosteum. In other instances,

Figure 1. Active osteoclasia and fibrosis, periosteum of iliac crest, 105X, 44-year-old man, resident 40 years of a community with a natural fluoride level of 2.5 ppm.

Figure 2. Active osteoclasia and fibrosis, periosteum and cortex of lumbar vertebra, 105X, 59-year-old man, control series.

new bone pushed up the periosteum in a trabecular pattern. Sometimes foci of bone were found in the parosteal tissue with no apparent connection to the subjacent bony cortex.

Irregularity in contour in some fields was due to old or active periosteal osteoclasia (figs. 1 and 2). Sometimes gaps were visible in the bone where blood vessels entered and the periosteum appeared to be the only barrier between the marrow and adjacent marginal tissue, particularly in the sections of vertebrae. The majority of the frayed or fuzzy papillary projections of bone and basophilic material appeared to be old and unaccompanied by cellular proliferation. However, small strips or foci of bright, eosinophilic, new and incompletely calcified bone (osteoid) could be observed also. Often cuboidal or columnar osteoblasts were seen nearby.

Surface irregularity was frequently found near the sites of tendon insertion in the sections of iliac crest in both groups. Often it was accompanied by cartilaginous changes and irregular basophilic staining presumably due to calcification (fig. 3). Irregularity due to extension of cartilaginous and basophilic stained material along the front periosteal surface away from the intervertebral joint and toward

the midlevel of the vertebral body was often seen.

The criteria used in grading excessive bone or calcium deposition were based on the maximum degree of projection from adjacent surfaces as measured by an ocular micrometer, the maximum foci per standard low-power microscopic field, the number of fields affected, and the presence of extraperiosteal bone or basophilic stained foci independent of the adjacent cortex. Bones from the fluoride and control groups were examined alternately.

Irregularity in periosteal contour due to excessive bone or calcium deposition, or both, was found in 48 of a total of 94 satisfactory bone sections in 25 of the 33 controls (table 1). Similar changes were present in 35 of a total of 99 satisfactory bone sections in 24 of 37 fluoride-exposed persons. 2 to 4 multinucleated osteoclasts per low-power field associated with Howship's lacunae and present in more than one field. Grade ++, or moderate, was based on at least 5 osteoclasts, and grade +++, or severe, on 7 or more osteoclasts per low-power field. On the basis of this scale, ++ osteoclasia was observed in 2 bones and + in another for a total of 3 bones with such periosteal changes in 3 controls (table 1). In the fluoride group 2 bones showed a + increase, 1 a ++, and 1 a +++ increase in activity for a total of 4 bones in 4 individuals.

Compact Cortical Bone

Recently deposited bone (osteoid) could be determined by eosinophilic staining of the matrix, as mentioned above. This was particularly impressive when layers of various ages were arranged side by side. Configuration of cement lines, degree of cellularity, and appearance and arrangement of osteoblasts and osteocytes also aided. In the compact portion, swelling of endosteal cells was sometimes observed on surfaces abutting the marrow cavity, within the Haversian canals or within large open endosteal spaces. Sometimes such cellular arrangement was also associated with strips of bright eosinophilic new bone (osteoid). Other fields showed new bone layers without evident cellular activity. Serial section in such instances might have disclosed the presence of osteoblasts nearby. Some zones revealed what appeared to be mobilization and swelling of

endosteal cells without evidence of new bone formation. This might have represented a preliminary phase in such a process.

The cortices of the rib and iliac crest were thicker than those of the vertebra, and the Haversian systems there were usually well defined. Sometimes, however, excessive decalcification made the lamellae appear delicate, poorly stained, and incompletely outlined.

An attempt was made to evaluate osteogenesis and osteoporosis objectively after the first survey of the material indicated that the differences in the amount of bone substance between the fluoride series and the controls would be slight, if there were any at all. No satisfactory method for such an evaluation could be

found in the literature, and the following approach was therefore devised:

To obtain an overall impression of representative thickness, the compact layer was measured with an ocular micrometer, and the two extremes, for the thickest and the thinnest points were recorded. All measurements were made with the same microscope, 10X ocular, and the lowest power or scanning objective, 5X N.A. 1.4. A rough calibration would be 1 oculomicrometer unit equals 0.1 mm. The iliac crest could not be measured satisfactorily because of marked irregularity of cortical contour. Hence only the measurements for the vertebra and the rib were used. Measurements of the cortex of the vertebral body adjacent to the hyaline articular cartilage were tabulated separately from those of the cortex of the vertebral body at other points, usually anterior and lateral. Osteoarthritic zones with spur or bridge formation were avoided as far as possible.

Statistical analysis of the measurements revealed no significant differences between the controls and the fluoride series (tables 2 and 3). The average coded measurements (square root of measurements) were 1.734 units for the controls and 1.550 for the fluoride series. The F value attributable to the difference was 3.74,

Figure 4. Increased deposition of osteoid tissue, rib trabeculae, 105X, 71-year-old man, resident 48 years of a community with a natural fluoride level of 4.0 ppm.

and the theoretical F value with 1 and 57 degrees of freedom was 4.01 at the 5 percent probability level of significance.

The mean measurements for the various bone categories (the lumbar vertebral cortex adjacent to the hyaline articular cartilage, the vertebral cortex elsewhere, and the rib cortex) did, however, differ significantly (tables 2 and 3). The F value attributable to differences in the measurements was 23.52, which is to be compared with the theoretical F value of 3.17. This comparison was independent of the fluoride-control comparison, and an adjustment was made for unequal numbers of bones in the three categories.

Abnormalities in bone architecture, such as irregular or excessive new bone deposition, resorption, excessive cellularity, fibrosis, and increased active osteoclasia were evaluated also. All bones were studied for these conditions.

Focal abnormality in cortical bone architecture was found in 2 bones in 1 control (table 4). Similar focal abnormality was observed in 4 bones in 2 of the fluoride group. An example of one type of abnormality observed, focal increased osteoid deposition, is shown in figure 4.

Table 4. Cortical and medullary bone changes in persons ingesting fluoride and in controls

Bone changes	Fluoride series		Control series	
	Number bones	Number persons	Number bones	Number persons
Total examined	99	37	94	33
<i>Compact cortical bone</i>				
Architectural abnormalities	4	2	2	1
Excessive active osteoclasia	20	15	15	10
<i>Spongy medullary bone</i>				
Architectural abnormalities	8	5	7	5
Excessive active osteoclasia	18	11	11	7

Active osteoclasia was believed increased slightly (+) in 10 bones, moderately (++) in 3 bones, and severely (+++) in 2 bones from 10 persons in the control series of 94 bones (fig. 5). In the fluoride group of 99 bones, osteoclasia was considered increased slightly (+) in 15 bones, moderately (++) in 4 bones, and severely (+++) in 1 bone from a total of 15 individuals.

Spongy Bone of Medulla

An attempt was made, though admittedly the results are approximations only, to determine trabecular breadth or thickness by ocular micrometer measurement, as was done with the cortex. The two extremes were recorded, and a representative value was tabulated. Abnormalities in bone architecture and evidence of increased osteoclasia were recorded also.

The average coded measurements for the spongy medullary bone are given in table 5. The differences in values between the controls and the fluoride series were not significant when the figures were analyzed statistically. However, as in the cortical bone analysis, a statistical difference was found between the values for the three bone categories.

Among the controls qualitative abnormali-

Table 5. Average coded measurements¹ for spongy medullary bone, fluoride and control series

Bone category	Fluoride series	Control series	Both series
All parts-----	1. 134 (97)	1. 126 (90)	1. 130 (187)

Iliac crest-----	1. 215 (32)	1. 264 (26)	1. 237 (58)
Rib-----	. 984 (29)	. 961 (33)	. 976 (62)

¹ Square root of measurements.

NOTE: Figures in parentheses are numbers of measurements.

ties were found in 7 bones in 5 persons (table 4). Focal architectural irregularity was seen in 6 bones, and a small osteoma, in the seventh (fig. 6). Similar focal irregularity in architecture was observed in 8 fluoride-exposed bones in 5 individuals. No tumors were found among the fluoride group.

Active osteoclasia was believed increased slightly (+) in 11 bones from 7 persons in the control series. In the fluoride group osteoclasia was considered increased slightly (+) in 14 bones, moderately (++) in 3, and severely (+++) in 1 bone from a total of 11 persons (fig. 7). In both groups active osteoclasia was often associated with osteoblastic activity and new bone deposition nearby. Variation in staining characteristics of the intercellular substance, configuration of the cement lines, degree of cellularity, and appearance and arrangement of osteocytes and osteoblasts, as mentioned in the discussion of the cortex, combined to provide fairly reliable impressions concerning relative ages of different bone layers.

Bone Marrow

Most marrow sections of both the fluoride and the control series showed active hematopoiesis. Of 93 satisfactory marrow sections in the control group, 63 were graded +++; 25, ++; 4, +; and 1 was considered atrophic. Interesting qualitative features of the marrow sections from the controls included focal lymphoid hyperplasia (11 sections), focal erythroid hyperplasia (9 sections), and focal myeloid hyperplasia (7 sections). In 3 there was focal

Figure 5. Increased active osteoclasia, vertebral cortex, 105X, 74-year-old man, control series.

proliferation of megakaryocytes. The marrow of one bone revealed rather extensive fibrosis, and that of another showed focal hyperplasia of eosinophils. There were thus 32 bones with focal qualitative marrow changes.

Of 97 satisfactory marrow sections in the fluoride-exposed group, 69 were graded +++ quantitatively; 23, ++; and 5, +. Comparative qualitative study showed 17 with focal lymphoid hyperplasia, 1 with focal erythroid hyperplasia, and 4 with focal myeloid hyperplasia for a total of 22 qualitative changes.

Intervertebral Lumbar Body Joint

Osteophytosis occurred in both groups in the form of "spurs" or "lips," sometimes bridges (figs. 8 and 9). The osteophytes were composed of irregularly arranged osteoid tissue and mature bone, irregularly calcified cartilage, and fibrous tissue often associated with increased osteoclastic activity (fig. 10). The marrow in the osteophytes was usually fatty and deficient in hematopoietic elements. Accompanying the above process were mixtures of bone, fibrous tissue, and haphazardly calcified cartilage at and near the attachment of the osteophyte to the line of junction between hyaline articular cartilage and cortical bony plate. The normally

Figure 7. Increased active osteoclasia, trabecula of lumbar vertebra, 415X, 69-year-old woman, resident 28 years of a community with a natural fluoride level of 2.5 ppm.

even contour along this line was usually disrupted. Varying degrees of thickening were noted in the subchondral bone along the line of attachment to the osteophyte. Large osteophytes were often associated with irregularity in appearance of that portion of the annulus fibrosus near the attachment of the osteophyte. Fibrillation, irregularly increased porosity, or cystic degeneration was observed. Clefts in the intervertebral joint matrix were seen in both groups and were impossible to differentiate from artefacts.

The periosteum and anterior longitudinal ligaments over the osteophytic process revealed only nonspecific fibrous thickening.

No inflammatory reaction was noted within the annulus fibrosus or the nucleus pulposus even with advanced osteophytosis. The central portion of the nucleus pulposus was usually porous in the younger subjects (30-39 years) of both groups. In such cases multiple, irregularly shaped, cystic zones were apparent. They contained amorphous eosinophilic material in which occasional viable-appearing cartilage cells could be identified.

The annulus fibrosus in the young patients in

Figure 6. Small osteoma, rib medulla, 105X, 35-year-old man, control series.

both groups consisted of fairly dense layers of sparsely cellular fibrous tissue. As this tissue approximated the nucleus pulposus, it was arranged in interlacing bands among cartilage cells.

Figure 8. Osteophyte, lumbar vertebral body, 14X, 62-year-old woman, resident 19 years of a community with a natural fluoride level of 2.5 ppm.

Figure 9. Fibrosis and increased osteoclasia in an osteophyte, lumbar vertebral body, 35X, 73-year-old woman, control series.

Figure 10. Increased active osteoclasia and fibrosis near osteophyte attachment, 105X, same bone and patient as in figure 9.

Also in the young patients the hyaline articular cartilage blended almost imperceptibly with the loose fibrocartilage or elastic cartilage of the nucleus pulposus and annulus fibrosus. Some variation in thickness was noted in the hyaline articular cartilage. The cartilage cells were arranged more regularly and their nuclei were oriented more nearly in parallel planes than those in the nucleus pulposus or annulus fibrosus. Occasionally, small clefts with loose connective tissue and capillaries penetrated the hyaline cartilage near its line of junction with the subchondral bone. The line of calcification was fairly even along this junction in the young patients, but prongs of cartilage extended beyond into the subchondral bone, and, similarly, microscopic prongs or tongues of bone and osteoid tissue projected upward into the hyaline articular cartilage. The marrow adjacent to the subchondral bone occasionally showed focal proliferation of delicate fibroblastic elements in the young patients of both groups.

In the aged patients of both groups cystic changes in the nucleus pulposus and fibrillar changes in the annulus fibrosus were more prominent. In the annulus near the periosteal junction, fibrosis and proliferation of vascular

Joint changes	Fluoride series	Control series
Total examined-----	31	35
Osteophytosis-----	12	18
Other evidence of osteoarthritis-----	4	5
Miscellaneous pathology-----	1	1

channels were sometimes observed. The vascular channels were occasionally arranged in clusters resembling telangiectasia.

Of 31 satisfactory sections of lumbar intervertebral joints from the controls, there were 12 with osteophytosis (table 6). The severity was rated arbitrarily from + to +++. In 6 persons it was graded +++, or severe. In the fluoride group of 35 satisfactory sections, there were 18 with osteophytosis. It was rated severe (+++) in 9. Other evidence of osteoarthritis included irregular proliferation of bone, osteoid tissue, cartilage, and fibrous elements disrupting the even line of junction of hyaline articular cartilage and subchondral bone. This irregularity was apart from that near the attachment of osteophytes described above. Such evidence of osteoarthritis was found in 4 controls and 5 of the fluoride group. Miscellaneous arthritic changes suggestive of trauma and accompanied by distortion of the joint were observed in one person in each series. There was no example in either series of rheumatoid spondylitis.

Discussion

Reports of microscopic bone changes in man after chronic exposure to fluorides are rare. Furthermore, some of the cases reported have been complicated by chronic disease that could have contributed to the changes. Roholm (2) reported 2 cases, 1 of which was complicated by a syphilitic infection. The other case occurred in a 68-year-old man exposed to cryolite for 25 years. The findings on gross and microscopic study included calcification of marginal tissues, ligaments, and tendons, increased thickening of the compact bone, irregular gran-

ular deposition of calcium in the intercellular substance, osteoid reaction around Haversian systems, and deposition of calcified fibrous tissue. The fluoride level of the bones was as high as 60 times normal values.

Another case, reported by Linsman and McMurray (3) and later listed in the Atlas of Orthopedic Pathology (4), was complicated by chronic renal disease. This occurred in a 22-year-old white man from a high-fluoride area in Texas. On microscopic examination his bones were described as having large trabeculae and "granular" architecture with lamellae which were irregular, not well seen, and with a tendency to fragmentation. Also described was some "condensation" of bone at the periphery of the trabeculae. The sternum contained 0.69 percent fluoride and the lumbar vertebra 0.75 percent.

In 1937 Bauer, Bishop, and Wolff (5) presented the findings in a worker exposed to phosphate rock containing about 4 percent fluoride. At necropsy the chemical concentration of the bones was 10 to 20 times normal fluoride values. The microscopic changes, reported only in a rib, included an increase in width of the cortex and thickening of the trabeculae. These investigators found no young osteoid tissue and no widespread deposits of calcium as described by Roholm. They observed little distortion of the normal bone architecture except reduction in the diameter of the Haversian canals and encroachment upon the marrow.

Weinmann and Sicher (6) advanced a tentative theory of the effects of fluorides in older persons and animals: first, there is a slow and incomplete destruction of compact bone and partial transformation into spongy bone; then, fairly dense osteophytes of both immature and mature bone and narrow osteoid seams are laid down as compensatory reinforcement, most prominent near the periosteum.

In our study microscopic changes in ligaments, parosteal tissue, and the periosteum were more numerous in the controls than in the fluoride series. Nothing comparable to Roholm's findings of calcification of marginal tissues, ligaments, and tendon was observed. Focal calcification and cartilaginous changes of the periosteum and adjacent tendon or fascia of the iliac crest were seen with equal frequency

and intensity in both the control and the fluoride groups and were interpreted as normal.

Statistical analysis of measurements of bone mass in the cortex and medulla revealed no significant difference between the controls and the fluoride series. Since the fluoride group was approximately 12 years older than the control group (table 7), the differences in occurrence of osteoclasia and osteophytosis were studied further to determine whether there was any relation to age.

Table 7. Average age (in years) of persons supplying bone and joint specimens for microscopic examination

Sex	Fluoride series	Control series	Both series
Both sexes...	67.8 (37)	55.6 (33)	62.0 (70)
Male.....	64.5 (17)	54.0 (24)	57.3 (41)
Female.....	70.5 (20)	60.0 (9)	67.2 (29)

NOTE: Figures in parentheses are numbers of persons.

Ten of the 15 bones with increased active osteoclasia in the cortex of the controls were from 6 persons 60 years of age or over. There were 41 bones from 14 subjects in this age category; thus the incidence of increased osteoclasia, by bones, was 24.4 percent. By contrast 16 of the 20 bones with increased cortical osteoclasia in the fluoride series were from 16 persons 60 years of age or over. There were 68 bones from a total of 26 subjects in this age category for an incidence, by bones, of 23.5 percent.

Increased active osteoclasia in the medulla was similarly considered. Eight of the 11 bones of the controls with that finding were from 5 persons 60 years of age or over. Thus, the incidence for the 41 bones from this age category was 19.5 percent. In the fluoride series 17 of the 18 bones with that finding were from 10 persons aged 60 or over. The 68 bones from that age group yielded an incidence of 25.0 percent.

Examination of lumbar intervertebral body joints showed an increase in osteophytosis in the fluoride series. Many roentgenologists and orthopedists feel that osteophytosis in the lum-

bar vertebrae is not in itself to be considered a manifestation of arthritis or a cause for symptoms or disability (7, 8). Schmörl (9) found spinal osteophytes in 90 percent of all women over 60 years of age. On analyzing our data in the light of the difference in average age between the two groups, the difference in incidence of osteophytosis almost disappears. Nine of 13 patients, 69.2 percent, 60 years of age or over among the controls had osteophytosis as compared with 16 of 24, 66.0 percent, in the same age category in the fluoride series.

The differences in incidence of architectural abnormalities were not significant. Bone marrow examinations showed focal qualitative changes of minor importance. They were more frequent in the controls than in the fluoride series.

The results of this study can be correlated to some extent with previous work on necropsy material in Colorado Springs, where the fluoride level is 2.5 ppm (1). In that study there was no significant difference in the occurrence of bone cancer between 334 long-term residents (more than 20 years) and 188 short-term residents (less than 5 years). There were 3 deaths attributed to bone cancer in the former group and 2 in the latter. The microscopic study of bones adds further support to the belief that fluoride in drinking water at a level of 1.0 ppm can be ingested without cumulative toxic effect.

Summary

Microscopic examinations were made of 99 bones from 37 persons coming to necropsy who had resided 10 years or more in communities where the drinking water contained 1 to 4 ppm of naturally occurring or artificially added fluoride. Ninety-four bone specimens from 33 controls who had lived in areas where the drinking water contained less than 0.5 ppm fluoride were used for comparison.

In addition to the bone specimens, the lumbar intervertebral body joints of the subjects were examined.

The microscopic examinations showed no significant differences between the fluoride-exposed group and the control group that could be related to fluoride intake. Microscopic changes

in the bones and joints incidental to aging and due to non-fluoride-related conditions were observed in both series.

Radiation Protection

The New Jersey Legislature has created a Commission on Radiation Protection in the State department of health. The recently approved Radiation Protection Act specifically details the duties and responsibilities of the health department and the newly created commission.

The commission, consisting of five scientifically trained members appointed by the Governor and serving 4-year terms without compensation, will adopt, promulgate, amend, and repeal codes, rules, and regulations that may be necessary to prohibit or prevent unnecessary radiation.

Policies and programs developed by the health department under authority of this act will be reviewed by the commission. The commission, when requested, will also provide the department with technical advice and assistance.

The health department's responsibilities with regard to radiation protection will encompass administration, personnel, program development and evaluation, consultation with interested or affected groups, research, training, and demonstrations, health education and

information, review of plans and specifications for the design and shielding of radiation sources, and inspection.

The act requires "all sources of radiation shall be shielded, transported, handled, used, and kept in such manner as to prevent all users thereof and all persons within effective range thereof from being exposed to unnecessary radiation." The health department is empowered to issue orders directing persons to cease and abate causing, allowing, or permitting "unnecessary radiation." In the event of an emergency, the health department has the right to order immediate compliance with codes, rules, and regulations laid down by the commission, and it may bring civil action in the Superior Court to prevent violations of the provisions.

No ordinance, resolution, or regulation concerning unnecessary radiation adopted by any municipality, county, or local board of health can be effective, according to the act, until a certified copy of such ordinance or regulation has been submitted to the commission and approved by the commissioner of the health department.

Analysis of the rib, iliac crest, vertebra, and sternum for fluoride indicates a direct increase in bone fluoride with an increase in fluoride in drinking water up to 4.0 ppm.

Fluoride deposition in human bones

after prolonged ingestion of fluoride in drinking water

I. ZIPKIN, Ph.D., F. J. MCCLURE, Ph.D., N. C. LEONE, M.D., and W. A. LEE, B.S.

IN CONJUNCTION with microscopic examination of human bones for possible effects of prolonged ingestion of fluoride in drinking water (reported in this issue by Geever and associates, pp. 721-731), essentially the same bones were analyzed for ash and fluoride. These bones were obtained at autopsy from 69 persons, 36 of whom were exposed to 1.0 to 4.0 ppm fluoride for 10 to 76 years. The remaining 33 had lived in areas with less than 1.0 ppm fluoride for 10 to 87 years.

This study represents the first systematic survey of the fluoride concentration of bones of individuals exposed to various concentrations of fluoride in drinking water. Previous studies of exposure to high levels of fluoride, recently reviewed by McClure and associates (pp. 741-746 of this issue), have dealt with no more than

four cases (1-5). More extensive data have been reported on the fluoride concentration of selected bones of individuals in low-fluoride areas (6-8).

Most of the persons whose bones were examined in the present studies died suddenly, the chief causes being trauma, coronary heart disease, and cerebrovascular accidents. Although bones of persons with chronic illness or diseases known to affect bone structure were excluded from the microscopic study, they were included in the fluoride deposition study so that the effect of such conditions might be observed. The fluoride analysis thus included bones from 3 individuals with a malignancy and 3 with renal disease.

The 69 individuals in the fluoride deposition study, 40 men and 29 women aged 26 through 90 years, provided 190 bones and 64 specimens of intervertebral cartilage. Approximately 80 percent of these bones and cartilage specimens were also examined histologically. The bones, consisting of a portion of the iliac crest, the lumbar vertebra, and the sixth rib, were fixed in 10 percent formalin at autopsy.

Dr. Zipkin and Dr. McClure, biochemists, are respectively assistant chief and chief of the Laboratory of Biochemistry, National Institute of Dental Research, Public Health Service. Dr. Leone is chief of medical investigations with the institute, and Mr. Lee is a chemist with the biochemistry laboratory.

¹ Resident of Baltimore, Md.; water fluoridated to 1 ppm in November 1952; received fluoridated water for 2 years.

² Residents of Washington, D. C.; water fluoridated to 1 ppm in June 1952; received fluoridated water 4, 2, 3, and 3 years, respectively.

The intervertebral cartilage was separated from the vertebra, and all specimens were cleaned of adhering soft tissues. Each sample was dried overnight at 105° C., broken into pieces, and extracted with alcohol for 8 hours and with ether for 4 hours. After the sample was ground to pass a 60-mesh sieve, a portion was ashed for 3 hours at 550° C. and analyzed for fluoride (9-11). The significance of the differences in means was calculated according to Fisher's *t* test for paired values. The sodium, potassium, calcium, magnesium, phosphorus, carbon dioxide, and citrate contents of these tissues will be reported later.

Bone Fluoride

The percentages of ash and fluoride in dry, fat-free bones for each individual in the study, grouped according to the level of fluoride in the drinking water, are recorded in tables 1 through 4. Ages and years of residence are also given, but it is not possible to detect any definite relation between the fluoride concentration and these factors.

The fluoride values for the 15 bones from the individuals who had a malignancy or renal disease were within the variations encountered for others in the same group (subject No. 5 in table 1; subjects Nos. 8, 10, and 11 in table 3; iliac crest, subject No. 1 in table 4) or slightly higher (subject No. 2 in table 2; rib and vertebra, subject No. 1 in table 4). No significance can be attached to the somewhat higher values since they occurred in individuals from the two

smaller groups (tables 2 and 4). Moreover, approximately a tenfold increase in fluoride concentration of the bones from the lowest to the highest fluoride areas (tables 1 and 4) was seen without any apparent tissue damage.

Less Than 1 ppm Fluoride

Individuals exposed to less than 1 ppm fluoride were residents of several localities, with fluoride concentrations in the drinking water varying from 0.1 ppm in New York City to 0.4 ppm in San Antonio, Tex. The mean was 0.2 ppm. Five persons in this group, aged 32 through 74 years, drank water fluoridated to 1 ppm fluoride for 2 to 4 years. The fluoride content of the bones of these five was within the variations encountered in other samples in this group (table 1).

On a dry, fat-free basis, the mean concentrations of fluoride in the various bones of individuals exposed to less than 1 ppm fluoride were similar, 0.041, 0.050, and 0.054 percent for the iliac crest, the rib, and the vertebra, respectively. As expected, the fluoride concentrations of the rib and the vertebra were generally highest in the individuals from San Antonio.

Five samples of sternum from this group varied from 0.040 to 0.101 percent fluoride with a mean, \pm standard error, of 0.066 ± 0.012 percent (not including one inordinately high value of 0.229 percent fluoride). On an ash basis, they ranged from 0.078 to 0.188 with a mean of 0.134 percent. The mean concentration of fluoride in the ash of the vertebra (0.112 ± 0.010

Table 2. Percentage ash and fluoride in dry, fat-free bones of individuals ingesting drinking water containing 1 ppm fluoride, Grand Rapids, Mich.¹

Subject No.	Sex	Age (years)	Residence (years)	Iliac crest		Rib		Vertebra

¹ Fluoride added to drinking water January 1945. Subjects received fluoridated water for 12 years with exception of male aged 82 years.

percent) was similar to that of the sternum ash (0.134 ± 0.023 percent), but it was significantly higher than that in the ash of the iliac crest (0.072 ± 0.006 percent, $P < 0.01$) or in the rib (0.086 ± 0.008 percent, $P < 0.05$).

While ash concentrations of the vertebra and the sternum were similar (49.0 percent and 49.4 percent), they were significantly lower than that of the iliac crest (57.4 percent, $P < 0.01$) or the rib (58.8 percent, $P < 0.01$).

Fluoride Level of 1 ppm

A second group, composed of 5 persons, were residents of Grand Rapids, Mich., where the water supply was fluoridated to 1 ppm in January 1945. The autopsy specimens were obtained between November 1956 and January 1957; thus exposure to 1 ppm fluoride was for a maximum of 12 years during the last years of life.

As with the low-fluoride group, no differences were found in the concentration of fluo-

ride in the various bones of this group (table 2). On a dry, fat-free basis, the mean percentages were 0.138 for the iliac crest, 0.139 for the rib, and 0.160 for the vertebra. The fluoride concentrations of the ash of the iliac crest (0.225 ± 0.026 percent) and of the rib (0.241 ± 0.030 percent) were similar, but they were significantly lower than that of the vertebra (0.323 ± 0.043 percent, $P < 0.05$). Appreciable amounts of fluoride thus accrued during the last 10 to 12 years of life of these 5 individuals aged 64 through 85 years.

For the 5 exposed to 1 ppm fluoride, the concentrations of ash in the iliac crest (61.2 percent) and the rib (57.4 percent) were similar but significantly higher than that of the vertebra (50.0 percent, $P < 0.01$).

Fluoride Level of 2.6 ppm

Colorado Springs, Colo., and Amarillo, Tex., were the residences of 27 subjects. Colorado Springs has had a uniform and verified history

of 2.5 ppm fluoride within narrow limits for some 75 years (12, 13). The fluoride level of the water of Amarillo from 1934 to 1948 ranged from 3.6 ppm to 6.2 ppm (14). According to a personal communication from the city chemist, 33 new wells were added between 1948 and 1953, and the fluoride level ranged from 2.6 to 3.2 ppm. In 1955 and 1956 the water supply of Carson County, which probably contains less than 1 ppm fluoride inasmuch as Dean (15) considered the incidence of mottled enamel virtually negative, was developed to augment that of Amarillo. In 1957, 92 wells were pumping into the Amarillo reservoir, and the fluoride content averaged 1.6 ppm. From 1948 to 1957, the fluoride level of the drinking water in Amarillo averaged 2.8 ppm, and the weighted mean for the two cities was 2.6 ppm.

For the 27 individuals, the mean fluoride concentration, on a dry, fat-free basis, of the iliac crest was 0.267 percent; of the rib, 0.257 percent; and of the vertebra, 0.286 percent (table 3). On an ash basis, the mean concentration of fluoride in the vertebra (0.598 ± 0.015 percent) was significantly higher than that in the iliac crest (0.450 ± 0.040 percent, $P < 0.01$) or in the rib (0.432 ± 0.036 percent, $P < 0.01$). The concentration of ash in the iliac crest and the rib (59.7 percent) was significantly higher than that in the vertebra (48.3 percent, $P < 0.01$).

Fluoride Level of 4.0 ppm

Prolonged exposure to about 4.0 ppm fluoride in the drinking water took place in Lubbock, Tex., now the largest community in the United States reported to have this much fluoride. Because of the unusually high fluoride content of

its drinking water, Lubbock, as well as Amarillo, has been the scene of a number of previous studies of the effects of fluoride (14-18). The water fluoride of Lubbock up to 1948 ranged from 3.5 to 4.4 ppm (14). In a recent letter from the Lubbock City-County Health Department, the fluoride content of the water supply from storage reservoirs was reported to have varied from 3.1 to 5.2 ppm from 1948 through 1955, with a mean of 4.0 ppm. The four subjects from Lubbock were autopsied from May through July 1955.

For the Lubbock residents as for the other subjects, the fluoride concentrations of the dry, fat-free iliac crest, rib, and vertebra were not significantly different, being 0.413, 0.398, and 0.411 percent, respectively. Although the concentration of fluoride in the ash of the vertebra (0.802 ± 0.109 percent) was greater than that of the iliac crest (0.687 ± 0.081 percent) or that of the rib (0.629 ± 0.095 percent), the difference was not significant ($P > 0.05$). The ash content of the iliac crest (59.9 percent) and that of the rib (57.5 percent) were similar but higher than the ash content of the vertebra (50.7 percent). An unusually high value of 59.9 percent ash for a specimen of vertebra prevented any level of significance being attached to the difference in the mean ash content of the various bones.

Group Comparison

To summarize these data, the mean concentrations of fluoride in the various bones were plotted against the fluoride level of the drinking water to which the individuals were exposed (see chart). The result indicates that the relation between fluoride in the bones and fluoride

Relation of fluoride in dry, fat-free bones to fluoride in drinking water.

in the drinking water up to 4.0 ppm is adequately described by a straight line function.

Other Findings

The concentration of fluoride in the dry, fat-free intervertebral cartilage also appeared to increase somewhat with elevated levels of water-borne fluoride (table 5). Calcification of this tissue, however, appears not to have been affected by the fluoride concentration of the drinking water.

In addition to the fluoride and ash analyses reported in the preceding tables, it may be of interest to note that the fat content of neither the bones nor the intervertebral cartilage was

related to the fluoride content of the drinking water. The mean concentrations of fat in the oven-dry bones had the following range:

	Fat content (percent)	
	Lowest	Highest
Iliac crest.....	23.2 ± 5.7	35.3 ± 2.6
Rib.....	23.4 ± 3.6	30.2 ± 5.7
Vertebra.....	32.2 ± 7.6	43.8 ± 4.3
Sternum ¹	41.3 ± 4.3	41.3 ± 4.3
Intervertebral cartilage...	1.8 ± .2	3.3 ± .8

¹ Only one fluoride group examined.

Discussion

The fluoride concentrations in the bones examined in the present study from both low-fluoride areas and high-fluoride areas approximate those observed in the previous limited studies (tables 6 and 7). For one resident of London, a low-fluoride area, a very high value of 0.687 percent fluoride in rib ash was obtained (7). The highest concentration of fluoride found in the present study in bones of individuals who had been drinking water containing less than 1.0 ppm fluoride was 0.428 percent in a sample of ashed sternum, and the next high value was 0.238 percent fluoride for a sample of vertebral ash. In considering the data for high-fluoride areas, some reservations must be attached to the high values presented by Kilborn and associates (5), since these results may have been due to the subnormal living standards and the low nutritional status of this area (Chengtu, China).

Fluoride in the drinking water up to 4.0 ppm did not affect the ash content of any of the bones analyzed.

For any given level of fluoride in the drinking water, the mean concentrations of fluoride in the

Table 5. Percentage ash and fluoride in intervertebral cartilage in relation to fluoride level of drinking water

dry, fat-free iliac crest, rib, and vertebra were similar. On an ash basis, however, the fluoride concentration of the vertebra was significantly higher than that of the rib at fluoride levels up to 2.6 ppm. At higher amounts of fluoride in the drinking water, this difference did not obtain.

Previous studies dealing with fluoride deposition in the white rat (20-22) and urinary fluoride excretion by the rat (23) and by man (24,25) have indicated that as bone ages it may lose some of its capacity to store fluoride. This decrease in fluoride deposition with increasing age has been presented in graphic form by Hodge (26) based on the data on man of Smith and associates (7). In the present study, most of the subjects were of advanced age, and the

means for the four groups varied only from 55.5 to 75.6 years. Hence, on the one hand, it was unlikely that a relation between fluoride deposition and age would be apparent; on the other hand, the age factor would tend not to bias any relation between bone fluoride and water fluoride.

From this extensive survey on the fluoride content of human skeletal tissues, it appears that the deposition of fluoride is directly related to the fluoride content of the drinking water up to 4.0 ppm. The deposition of fluoride in dentin and enamel is also elevated proportionately with an increasing concentration of fluoride in the drinking water (27).

There is no indication in these data or in those of previous studies that these human calcified

tissues approach their theoretical capacity of about 3.5 percent fluoride, although drinking water containing as much as 4.0 ppm fluoride was ingested. Prolonged exposure to the water of Colorado Springs, Colo., and Amarillo, Tex. (2.6 ppm fluoride), and to that of Lubbock, Tex. (4.0 ppm fluoride), elevated the fluoride content of the bone ash to a maximum of 1.080 and 1.103 percent, respectively.

The data from the five subjects of Grand Rapids, Mich., are of special interest. Exposure to water containing 1 ppm fluoride did not exceed 12 years, and the average age of the subjects at the time they started to use fluoridated water was about 63 years. Nevertheless, a mean concentration of 0.146 percent fluoride on a dry, fat-free basis was found in these relatively old bones, compared with an average value of 0.049 percent in the bones of individuals of an average age of 56 years ingesting water containing less than 1.0 ppm fluoride.

The fluoride data in the present study coupled with the microscopic findings on essentially the same individuals constitute substantial evidence that a concentration of fluoride as high as 0.548 percent in the dry, fat-free bone and 1.080 percent in the bone ash (for subjects in both studies) may be present without producing any apparent tissue damage.

Summary

Selected bones and skeletal tissue—iliac crest, rib, vertebra, sternum, and intervertebral cartilage—obtained from 69 individuals 26 through 90 years of age who had drunk water containing 0.1 to 4.0 ppm fluoride for at least 10 years were analyzed for ash and fluoride. These bones, which showed no significant histological changes, contained up to 0.548 percent fluoride on a dry, fat-free basis and 1.080 percent fluoride on an ash basis. The mean ash content of the iliac crest and ribs varied from 57.4 to 61.2 percent and that of the sternum and vertebra from 44.6 to 53.7 percent.

At any given level of fluoride in the drinking water, the various bones contained, on a dry, fat-free basis, similar concentrations of fluoride. The fluoride concentration of the intervertebral cartilage was considerably less than that of the bones.

The concentration of fluoride in the bones increased in an essentially linear fashion with an increase of fluoride in the drinking water up to 4.0 ppm.

Training in Radiological Health

Sanitary Engineering Center. A course in the medical and biological aspects of radiological health will be given at the Robert A. Taft Sanitary Engineering Center, Public Health Service, October 20-31, 1958. Designed for medical, dental, and biological personnel responsible for program decisions in Federal, State, and local health agencies, the course will present data pertinent to radiological health program planning, with emphasis on radiation exposure in the healing arts.

Areas to be covered include biological effects of radiation, philosophy and procedures of radiation protection, practical methods of reducing exposure from medical and dental X-rays, administrative problems of a radiological health program, and the current status of legislative and regulatory procedures.

No previous formal training in radioactivity or radiation is necessary, and there are no tuition or fee charges. Application forms and further information concerning the course may be obtained from the Robert A. Taft Sanitary

Engineering Center, 4676 Columbia Parkway, Cincinnati 26, Ohio.

University of Pittsburgh. Beginning in 1958-59, 2- and 3-year courses in the health aspects of nuclear technology leading to master's and doctor's degrees will be offered by the Graduate School of Public Health. Although focused on occupational and health aspects of nuclear reactors, the new program will cover the fields of health physics and radiation biology. In addition to graduate school facilities, other University Medical Center facilities and some community installations will be used.

Pittsburgh's radiation health training program, located in the department of occupational health, was made possible by a 10-year grant from the Rockefeller Foundation. An additional grant of \$30,000 awarded by the Atomic Energy Commission will be used for equipment and instruments.

Applications and more information may be obtained from the Secretary, Graduate School of Public Health, University of Pittsburgh, Pittsburgh 13, Pa.

Chemical analyses of the bones of two women indicate that human bone may contain as much as 0.5–0.6 percent fluoride without being adversely affected.

Excessive Fluoride in Water

and Bone Chemistry

Comparison of two cases

F. J. McCLURE, Ph.D., H. G. McCANN, M.S., and N. C. LEONE, M.D.

CHEMICAL analyses of skeletal tissues of two women have provided new data on the effect on bone composition of excessive amounts of fluoride in drinking water. One of these women, subject A, 74 years old, lived for 24 years prior to death in Washington, D. C., where the drinking water contained 0.2 ppm fluoride. The other, subject B, died at 78 years after 34 years of residence in Bartlett, Tex., where the drinking water contained 8.0 ppm fluoride. Subject B, whose death was caused by a cerebral vascular accident, was a member of a population group previously studied (1). Subject A died of a heart attack.

The ingestion of fluoride and its concomitant occurrence in the animal body has been studied previously and extensively by the analysis of various tissues of cattle, sheep, swine, and small laboratory animals (2–12). Similar data for man, however, are limited and apply practically entirely to the bones and teeth.

The authors are all with the National Institute of Dental Research, Public Health Service. Dr. McClure is chief, and Mr. McCann is a staff member of the Laboratory of Biochemistry. Dr. Leone is chief of medical investigations.

Roholm (2) tabulated the results of the fluoride analyses of human tissues available in the literature up to 1937. His fluoride data, expressed as a percentage of the bone ash, are considered normal for the bones of adults without unusual exposure to the mineral. Values ranged from 0.05 to 0.21 percent fluoride.

He also reported the fluoride content of bones of two men who had been employed in the handling of cryolite and were thereby exposed to excessive quantities of the dust of this fluoride-containing mineral. The ash of bone specimens from these two cryolite workers contained as much as 1.31 percent fluoride.

Boissevain and Drea (13) reported 0.12–0.35 percent fluoride in ash of human rib bones after 15–40 years of exposure to a domestic water containing 2.5 ppm fluoride. They found 0.07 percent fluoride in ash of one human rib with no known exposure to a fluoride drinking water. Linsman and Murray (14) attributed a case of so-called fluoride osteosclerosis to the use of drinking waters containing 4.4–12.0 ppm fluoride. The ash of the sternum and that of lumbar vertebral body were reported to contain 0.69 and 0.75 percent fluoride respectively.

In 1938 Wolff and Kerr (15) analyzed the

skeletal tissues of a man, 48 years of age, exposed almost daily for 18 years to the dust of rock phosphate (3.88 percent fluoride). According to their data, based on 9 different bone specimens, 0.18-0.70 percent fluoride was present in the dry, fat-free bone.

Kilborn and co-workers (16) observed not only a high incidence of mottled enamel in the inhabitants of a remote province of China but also a chronic skeletal disease which they attributed to fluorosis. The drinking water used in two villages contained 6.3 and 5.9 ppm fluoride. A native of one of these villages, a 37-year-old man, was autopsied after accidental death. Sixteen different bones from this man averaged 1.27 percent fluoride in the dry bone and 1.91 percent fluoride in the bone ash. The results varied from 0.97 to 1.50 percent fluoride in dry bone and from 1.47 to 2.20 percent fluoride in bone ash.

The fluoride in the ribs of humans of different ages with no known abnormal exposure to fluoride was studied by Glock and associates (17). Although considerable variation occurred, there is evidence of an increase in skeletal fluoride concomitant with advancing age. Their results, which appear to be somewhat high, are:

Age (years)	Percent fluoride in fat-free bone	Percent bone ash
Under 1	0.024	-----
Under 1	.033	-----
2	.06	0.115
15	.088	.174
22	.18	.397
25	.061	-----
27	.28	.591
32	.089	.194
37	.31	.687
37	.15	.280
54	.23	-----
59	.09	.186
60	.23	.473
68	.18	.380

This relation to age has been studied more recently by Smith and associates (18). In the age group 81-90 years, the fluoride in skeletal ash averaged a little more than 0.128 percent but ranged from 0.034 to 0.331 percent for 10 samples of rib and vertebra. Although marked variations thus occurred in the data for individuals of the same chronological age, these authors state that there is "a striking approximation to a linear relationship for the average

bone fluoride concentrations when 10-year age groups are plotted against the logarithm of the age." These normal accumulations of skeletal fluoride were associated with the use of a drinking water containing 0.06 ppm of fluoride.

In a more recent study, the fluoride content of the iliac crest was found to vary from 0.0164 to 0.0505 percent on dry, fat-free bones in persons aged 32-84 years who had no known exposure to a fluoride water (19). Extensive data on the relation between fluoride in drinking water and fluoride in skeletal tissues are reported by Zipkin and associates (see pp. 732-740 of this issue of *Public Health Reports*).

It is evident from these bone analyses that fluoride may accumulate in skeletal tissues concomitant with the ingestion of fluoride. The presence of relatively large quantities of fluoride in drinking water would be expected to cause marked increases in skeletal fluoride after a prolonged exposure. This was found to have occurred in the woman of this study exposed to high-level fluoride water.

While a major interest in the chemistry of these human skeletal tissues is the extent of fluoride accumulations, it was our purpose also to throw some light on the relation of fluoride to other bone elements, particularly those concerned with calcification. Accordingly, the ash, calcium, phosphorus, magnesium, and carbon dioxide contents of the bones were determined.

Methods and Results of Analyses

For the chemical analyses, the bones were reduced to small pieces; the fat was extracted with alcohol and ether; and the sample was ground to pass a 60-mesh sieve and then dried at 110° C. A temperature of 600° C. was maintained in the electric muffle furnace for ashing. Fluoride was determined on the ashed sample by standard procedures (20, 21), which require steam distillation using perchloric acid and titration of the fluoride evolved in the distillate with standard thorium nitrate. In addition to fluoride, calcium was determined on the ashed samples by triple precipitation of the oxalate from acid solution by slow addition of NH_4OH to avoid contamination with phosphate and to assure good separation of mag-

nesium (22). Final weighing was as CaF_2 . Magnesium was determined in the filtrate by double precipitation as magnesium ammonium phosphate. Phosphorus was determined on the unashed sample by the molybdovanadophosphate differential spectrophotometric method (23). Carbon dioxide was determined on the unashed samples by evolution with HClO_4 and absorption of the dried gas in a weighing bulb, a modification of the standard procedure (22).

In Table 1 the analytical data are presented

on the dry, fat-free bone. As might be expected, the most remarkable difference in the chemical content of the bones of these two aged adults lies in the fluoride. As much as 0.653 percent fluoride was present in the calvarium of the Bartlett woman, subject B, with a minimum of 0.512 percent fluoride present in the fibula. In striking contrast, the maximum percentage of fluoride in the skeletal tissues of the control, the nonfluoride subject A, was 0.092 percent in the calvarium. The fluoride concen-

trations in all the different dry, fat-free bone specimens were relatively constant.

Table 2 shows the percentage composition of the bone ash of the two women. It will be noted that the femur and fibula ash of B contained somewhat less fluoride, 0.771 percent and 0.715 percent respectively, than did the other specimens of bone ash of B; which were quite uniform and ranged from 0.855 to 0.966 percent fluoride. The femur ash of A also contained less fluoride than did the ash of other bones. One explanation of this observation may be the higher ash content of these bones.

Some differences in the ash, calcium, and perhaps phosphorus, in addition to fluoride, in the dry, fat-free bones of these two particular women occurred (table 1). In 5 possible comparisons of the same bones from these 2 similar individuals, more ash, calcium, and phosphorus were contained in the bone specimens of B than in those of A. These differences are most pronounced with respect to ash and calcium. There is a suggestion of some elevation in percentage of carbon dioxide in the bones of B compared with A. The calcium-phosphorus ratio and the magnesium content of the two subjects were comparable.

Discussion

The results of the fluoride analyses of these human skeletal tissues agree with previous experimental and clinical evidence that skeletal

tissues become an extensive depository of fluoride. The fluoride accumulations found in B resulted from the prolonged use of a drinking water containing an excessively high concentration of fluoride. As indicated by comparison of the data for these two subjects, this accumulation of fluoride increased slightly the calcification of skeletal tissue.

The ash and perhaps the calcium of dry, fat-free bones of B were slightly higher than the ash and calcium in normal human bones, as shown in table 3. Fluoride analyses of the bone specimens from normal subjects, previously studied by Illinois investigators (24-26), were made at the National Institute of Dental Research. Analytical data for the individual bones of A and B have been averaged and are presented for comparison with the other findings.

There is a remarkably close agreement among the data obtained on the normal men and on our own normal subject A. Whereas the ash values of the bones from these subjects varied from 56.67 to 57.85 percent, the ash content of the bones of subject B averaged 64.91 percent. The calcium averaged 24.16 percent compared with a variation of 21.26 to 22.84 percent in adult bone exposed to low-fluoride water. There is no indication of an effect of fluoride on the calcium, phosphorus, and calcium-phosphorus ratio of the bone ash.

It seems evident, considering the data in table 3, that a slight increase in calcification did occur

Table 3. Comparison of composition of human skeletal tissue exposed to normal and high-fluoride water.

Subject and exposure	Dry, fat-free bone					Bone ash

in the skeletal tissues of B. This is regarded as the result of exposure to excessive water-borne fluoride.

Bone Pathology and Fluoride Content

For previous evidence bearing on the relationship between fluoride content and pathological changes in human bone tissues, we must refer to the early classic studies of Roholm (2). The two autopsy cases he studied represent the characteristic skeletal pathology produced by excessive fluoride. The abnormalities were concomitant with 0.76 to 1.319 percent fluoride present in the ash of the affected bones. An unusually low value of 0.31 percent fluoride is reported for the frontal bone of 1 of these 2 cryolite workers.

The deleterious effects of fluoride, observed in experimental animal studies, have resulted consistently from excessive fluoride exposures, and the observations supply substantial information concerning the relationship between bone fluoride and bone pathology. Swine bones, according to Kick and associates (3), retained upwards of 0.30–0.40 percent fluoride before any toxic effects of fluoride were discernible. In the bones of dairy cattle suffering from extreme fluorosis, the severity of bone exostosis increased directly with the fluoride content, a mild form of exostosis being associated with 0.53 percent fluoride in the bone tissue (9).

Recently Suttie and associates (27) reported that dairy cows tolerated the ingestion of 30 ppm of fluoride in the diet, with a concomitant accumulation of 0.46 percent fluoride in dry, fat-free rib bones. On the basis of the evidence that 0.01–0.15 percent fluorine is present normally in the bone ash of animals, Peirce (6) suggested that the "ingestion of quantities of fluorine which apparently exert no untoward effects on the general health of animals or which bring about no obvious morphological change in its skeleton, may nevertheless increase ten- to fifteen-fold the fluorine content of bones and teeth."

The data available through the present study provide additional evidence regarding the threshold level of fluoride which may be tolerated by human skeletal tissues. As much as 0.5–0.6 percent fluoride in the bones of B did not

prove to be a physiological hazard. This is about 10 times the quantity of fluoride regarded as normal. X-ray examination, medical, and clinical studies made prior to the death of B (1,28) do not reveal any skeletal abnormalities or systemic conditions of consequence to health or well-being which could be directly associated with the remarkable increases in the skeletal fluoride content. Other reports contain extensive information on the relation between fluoride content and bone pathology (see pp. 721–731 and 732–740 of this issue).

It must be concluded in the light of the available evidence that human skeletal tissue may have a very high degree of physiological tolerance to accumulations of fluoride.

Summary

Analytic chemical studies of similar human skeletal tissues obtained at autopsy from two comparable women were conducted to determine the effect of a prolonged exposure to drinking water containing 8.0 ppm of fluoride on the chemistry of human bones.

As a result of the prolonged use of this fluoride drinking water, the fluoride in dry, fat-free skeletal tissues ranged from 0.512 to 0.653 percent, as compared with 0.062 to 0.092 percent fluoride in the skeletal tissues of a subject, comparable in age, height, weight, and sex, with no unusual water-fluoride exposure.

There was some indication that the prolonged use of drinking water containing 8.0 ppm fluoride accounted for an increase in the ash and a slight increase in the calcium content of the skeletal tissues.

The absence of any gross or systemic findings, or of any impairment of health or well-being, malformation of the skeletal tissues, or malfunction generally in the one subject studied, indicates that human bone may not be affected by as much as 0.5 to 0.6 percent fluoride. These findings compare favorably with other previous evidence pertinent to human bone as well as fluorosed animal bones.

Summary of a lecture at the National Academy of Sciences-National Research Council, Washington, D. C.

TRACE ELEMENTS in BIOLOGY and AGRICULTURE

WILLIAM D. McELROY, Ph.D.

FOODS and nutrients are necessary for cell growth because of their function in generation or release of energy, building and repair of protoplasm, and regulation of metabolic processes. They are usually classified as: (a) an energy source, (b) a nitrogen source, (c) growth factors (organic compounds not synthesized by the organism and required usually in small amounts), and (d) mineral salt or inorganic nutrient.

A number of inorganic elements, or minerals, are required by all living forms for normal growth and reproduction. This is not true of all the elements of the periodic table, although most have been found in living cells. The minerals essential to life are generally divided into two classes: macronutrients, or major elements, needed in relatively large amounts, and the micronutrients, or trace elements, required only in small amounts.

For most organisms the macronutrient elements include sulphur, phosphorus, potassium, magnesium, calcium, and nitrogen. In addition, sodium and chloride are needed by animals and, according to recent experiments, probably by plants as well. The trace elements include iron, zinc, manganese, and copper. Molybdenum, boron, and vanadium are

also needed by plants, and iodine, cobalt, and probably molybdenum by animals. Even though micronutrient elements are required in only extremely small quantities, they are no less important than the major elements.

The fact that the trace metals are needed in only small quantities indicates that they are functioning in some catalytic role, usually as part of an enzyme system. In this respect the function of trace elements is similar to that of the organic micronutrients, the vitamins. A known enzymatic role has been described for most of the trace elements. Exceptions are iodine, which is a component of the thyroglobulin molecule, and cobalt, which is part of the vitamin B₁₂ molecule.

Although we can describe a specific function for most of the metals, as long as essential enzyme systems can be activated by a variety of elements we can expect nonessential metals to have a significant effect on the metabolism of plants and animals. There are many examples of multiple-metal effects on enzyme systems, some of the most striking of which are from the area of plant-animal relationship. Judging by the optimum concentration of an element for enzyme activity as well as the ratio of stimulatory and inhibitory metals present, it is evident that under physiological conditions some systems may be working at a maximum rate whereas others may be operating at less than 1 percent of maximum efficiency.

Obviously there must be some balance in the

Dr. McElroy is professor of biology, chairman of the department of biology, and director of the McCollum-Pratt Institute, Johns Hopkins University, Baltimore, Md.

soil, in the plant, and in the animal which leads to a normal, healthy individual. However, the difficulty of determining the normal activator of a metabolic system and factors which will influence the rate of reaction *in vivo* is demonstrated by a number of recent experiments.

Is growth or yield an adequate criterion for determining whether the various metabolic systems are functioning at a level to give maximum benefit to the organism? Can we apply trace elements and other fertilizers to the soil and to the diets of animals until we obtain maximum crop yield or maximum growth rate and expect, at the same time, to receive maximum nutritional benefit for the organisms? There are several excellent examples which say we cannot. One might say that these are extreme and special cases. However, it is gradually becoming evident that visual symptoms of plant and animal deficiency are not necessary to prove deficiencies in the health and vigor of the organism. Deficiencies and excesses are a matter of degree, and plants, like animals, may become decidedly inferior in quality long before showing outward signs. Hence, yield or growth is no longer an adequate sign of health.

The next question is, what criteria can be used? From a physiological point of view, criteria must by necessity vary with the nature of the objective. If it is aroma in tobacco that is desired, then a plant that is slightly deficient in sulphur may be essential. If it is tensile strength and kink in wool, then the dietary level of copper may be one of the major factors. Many other examples could be cited.

What seems clear from numerous studies is that certain metabolic characteristics appear under conditions of varying trace-element supply and not merely in association with an overall reduction or increase in mass or quantity. In other words, each level of trace-element supply during growth produces a characteristic metabolic pattern irrespective of the yield. The enzymatic patterns are the real test. Enzyme concentration and activity are changing under all conditions of trace-element nutrition. These changes of enzymatic activity will certainly be of value in the early diagnosis of animal and plant diseases which are not apparent from growth studies, and, as Williams

recently emphasized, each individual represents a special problem (1).

Several general patterns evolve from the physico-chemical and nutritional studies on the influence and mechanism of action of metals in enzyme systems. Although there are exceptions to these generalizations, it appears that those metals most closely associated with electron transferring systems are copper, iron, zinc, and molybdenum. Nonenzymatic studies have shown that these metals have the inherent capacity to function as electron mediators in oxidation-reduction reactions. The important biochemical questions are: (a) why is this capacity for catalyzing oxidation-reduction reactions accentuated in the presence of specific proteins, and (b) what is the nature of the linkages which allow specific coupling of these metal systems to others, which in turn allows the transfer of electrons along specific pathways? The pattern that seems to be emerging is that these metals are not required specifically for the combination of substrate to the catalytic protein but rather that they function primarily as "electron couplers" from one protein system to another.

Tabulated results of studies show that magnesium and, to a certain extent, manganese are required primarily for those reactions involving group transfer, in particular those in which phosphate participates. For example, to metabolize glucose it must be phosphorylated. Phosphate is transferred from adenosine triphosphate to glucose to form glucose-6-phosphate and adenosine diphosphate. Magnesium is required for this group transfer. In recent years it has become increasingly clear that enzymes participate intimately in group transfer by serving as the intermediate carrier. Magnesium plays a predominant role in promoting the formation of the enzyme-substrate complex and the resulting intermediate of the reaction. The presence of a pyrophosphate structure in many of the co-factors and substrates involved in group transfer suggests that a chelate structure with magnesium is probable.

The predominant metal in general enzymatic decarboxylation and hydrolysis reactions is manganese. To a lesser extent zinc and magnesium also are factors. At present there is no general agreement as to the primary mechanism

of action of these metals. Some workers feel that they form an essential structure with the substrate and thus act to bring the substrate into combination with the protein. Others feel that the metal combines with the enzyme and functions primarily to accelerate and therefore to increase the concentration of an essential intermediate in the reaction. Manganese does not have strong inherent properties for catalyzing decarboxylation, whereas other metals, such as copper, which do not function as co-factors in enzymatic decarboxylation, are very effective in nonenzymatic reactions. The suggestion, therefore, that manganese functions in enzyme systems by forming chelate structures with the substrate lacks strong experimental support.

Conclusion

Emphasis in nutrition during the past 30 years has been on identification and establishment of absolute requirements of inorganic and

organic nutrients for "normal" growth and development. Almost by necessity it was assumed that the animals in a population were all identical and therefore had the same nutritional requirements. It is now clear, however, that there are large individual variations in nutritional requirements. In addition, quantitative studies on various tissues indicate that small changes in the diet often lead to dramatic effects on enzyme systems. Thus studies in the future must emphasize the individual.

Nutritional individuality can be an important factor in human health and disease. Small changes in concentration of the trace elements in the diet, for example, will alter the concentration of metabolic intermediates and products formed by an individual. Growth alone, therefore, is not the only criterion that can be used for testing the adequacies of a diet.

Mortality in mental hospital patients is analyzed in an exploration of its relation to changes in the general pattern of mortality.

Mortality in State Mental Hospitals of Michigan, 1950-54

GEORGE K. TOKUHATA, Ph.D., and VERNON A. STEHMAN, M.D.

MODERN science has not only extended average life but also has markedly affected the pattern of mortality in the United States. The effect of demographic factors associated with mental patients on an overall mortality rate and the trends and characteristics of mental hospital mortality have become subjects of interest and curiosity among professional investigators in the mental health field, including demographers (1-5).

The present study compares differential mortality rates among resident patients in Michigan State mental hospitals with those in the general population of Michigan during a 5-year period beginning in 1950. The source for the data on mortality of mental patients is the statistics section of the Michigan Department of Mental Health. Figures for the general population of Michigan for 1950 are from the United States census. To compute death rates, the number of resident patients and the number of people in communities as of June 30 were used as denominators. Analyses and discussions of the data are presented in the following order. First, age-sex composition of the population in order to provide the basic information that would facilitate intelligent discussion of the differential mortality rates observed in two different environments. Second, trends and characteristics of the mortality rates by all

causes of death. Third, trends and characteristics of the mortality rates by selected causes of death. Fourth, diagnosis-specific death rates among patients with different mental disorders. Fifth, psychiatric hospital mortality from the point of view of physical condition and age of patients on admission to the hospital.

Population Characteristics and Deaths

It is estimated that, during the 1950-54 period under study, Michigan's total population increased from 6,371,766 to 7,156,481, or by 12.3 percent. During this period total deaths in Michigan increased from 57,743 to 60,632 or by 5 percent. These changes led to a shift in the crude death rate, which declined from 9.1 to 8.6 per 1,000 of the State population.

In contrast, the number of resident patients in Michigan State mental hospitals increased from 18,738 to 20,031, or by 6.5 percent, while the number of deaths occurring in the hospitals during the same period decreased from 1,455 to 1,348, or by 7.4 percent. This brought about a sharp decline in the crude death rate for the patients from 77.6 in 1950 to 67.2 in 1954.

Examination of the available data indicates that patient movement during the quinquennium has shifted toward the hospitalization of increasingly more women than men in the middle and old age groups. Conversely, there has been increasingly more men than women of young ages in the hospitals for psychiatric treatment.

Dr. Tokuhata is research sociologist, and Dr. Stehman is deputy director, Michigan Department of Mental Health, Lansing.

Comparison of the general population with the patient population points up two obvious distinctions in the age composition. In the patient population there is an actual and proportionate preponderance in the middle and old age groups, with an extremely small number and proportion of people under 20 years of age, while in the general population, the largest proportion and number is in the youngest age group with a diminishing proportion as the age groups advance. On the other hand, the psychiatric hospital population usually consists of a large proportion of two distinctive diagnostic groups, namely, the schizophrenic patients who are mostly in the productive age groups, and the patients suffering from psychoses associated with senility.

Crude Death Rates by All Causes

The crude death rate, measured as the number of deaths per 1,000 of the total population, usually cannot be taken as an accurate index of the true mortality of the population. However, analyses and discussions of such rates are presented because of their pragmatic utility for health authorities.

Although the hospital population experienced a considerable decrease in the overall death rate, the data reveal no clear-cut and consistent pattern of change. It should be noted, however, that such an overall rate decline was actually accounted for by a remarkable drop in the rate of male patients during this period. Thus, it follows that, although male patients are gener-

ally subjected to a higher mortality than female patients, the death rate difference between the two sexes became continuously less important. On the basis of the 5-year average, approximately 20 more male than female patients per 1,000 died in the course of 1 year.

According to the data in table 1, the magnitude of decrease in the death rate is positively related to the age of the group. Particularly noted are the patients aged 65 and over, who recorded the sharpest decline, from 197.9 to 172.8, a drop of more than 25 deaths per 1,000. With male patients the death rate declined more in the older group than in the younger group, while the reverse was true with female patients, who showed a sharper rate drop in the younger group.

In sharp contrast to what was observed in the hospital population, the general population on the whole did not show a noticeable change in the crude death rate during the period being observed. In fact, in the general population the overall death rate for all causes remained almost unchanged at the level of 10-11 per 1,000. As expected, the male population as a whole always maintained a slightly higher rate of mortality than did the female population. On the 5-year average approximately four more men than women per 1,000 died yearly. Furthermore, both sexes managed to hold a fairly consistent relative position of the rate throughout the entire quinquennium.

The data in table 2 also reveal that the crude death rate for all causes in the general population declined steadily, but slightly, in each of

the three broad age groups during the same period. It was found, as in the case of hospital mortality, that the magnitude of a quinquennial rate decline was largest in the oldest age group. Differences in the crude death rates as observed between men and women in the general population seem far less significant than those observed in the hospital population.

In view of the extremely contrasting characteristics of the age-sex composition of the two populations, it was assumed that the crude rate of hospital mortality would far exceed that of general mortality. According to the 5-year average rates, the hospital mortality was found to be 6.8 times as high as the general mortality,

while the difference was slightly greater for the female (7.1 times) than for the male (6.1 times) population. The death rate difference between the two populations was found to be much greater in the young than in the old groups.

Age-Sex Specific and Standardized Rates

Examination of the data in table 3 indicates that in both populations the age-specific and age-sex specific death rates rise increasingly with advance in age. The age-sex specific rate is measured as the number of deaths of a given age-sex group per 1,000 of the population of that age-sex group. Similar to Malzberg's

findings (6), the largest relative difference in the age-specific and age-sex specific death rates between hospital and general populations was found in the young (20-24) age group. Most important, these specific rates of resident patients were always higher than those of the general population in every age group used in the table.

The mortality trend observed in the hospitals, as indicated by the standardized death rates, was a steady downward movement. The standardized rate is measured per 1,000 of the selected standard population with the adjust-

ment for age or age and sex. From the point of view of demographic significance, this drop is a remarkable change which took place within a period of 5 years beginning in 1950. There was also a considerable rate difference between the patients of different sexes, with the male patients showing a much greater decrease in adjusted mortality than did female patients during the same period.

In all age groups there was a steady and favorable trend in the adjusted mortality. In comparing the three age groups, it was found that the old age group showed a greater decrease

in the mortality rate than did the middle and young age groups.

In terms of adjusted mortality rate, it should be noted that the amount of improvement made by the young female patients was about twice that experienced by young male patients during the 5 years. In contrast, the pattern of such progress was reversed for the male patients in the middle and old age groups. In general the improvement on life expectancy of male patients was much greater than that of the female patients, with a consequent decreasing sex difference in the mortality rate among resident patients.

In short, it is apparent upon examination of the standardized death rates presented in the table that the downward movement of the mortality observed in State mental hospitals was not due to change in age-sex composition of the resident patient population. Rather it was because of the favorable impact of other environmental factors, or such factors as selective intake of patients so that the patients admitted in later years had a smaller risk of death, or to improvement in therapy which enabled patients to accept improved diets, thus improving their health.

In a 5-year comparison of the two popula-

tions, the adjusted hospital mortality rate was found to be 3.6 times as high as the adjusted general mortality rate (table 5), while no overall sex difference was noted. The greatest adjusted rate difference was found in the group aged 20-34 years, although such a discrepancy became consistently smaller during this period.

Crude Cause-Specific Rates

For the purposes of this paper, the definition of a cause of death, taken from the Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death, is "the morbid condition or disease process, abnormality, injury or poisoning leading directly, or indirectly, to death." A systematic classification of the causes of death as tabulated in the detailed list of the International List of Causes of Death was used in this study, and discussion of the basic mortality characteristics and trends is limited to the 12 leading causes of death. The cause-specific rate is measured as the number of deaths from a given disease per 100,000 of the total population.

The causes of death for patients in State mental hospitals show striking variations when compared with those for the general population.

Table 6. Percentage distribution of deaths by 12 leading causes for hospital population and general population, 1950-54

Note: Numbers in parentheses are category numbers of the International Statistical Classification, 1948.

Table 6 shows a percentage distribution of deaths by 12 leading causes for hospital and general populations respectively. In both populations, arteriosclerotic and degenerative heart disease ranked the highest among the 12 leading causes but, in the course of 5 years, the relative importance of heart disease as a cause of death has gradually and significantly decreased in mental hospitals as compared with an opposite trend observed in general communities. This may be partially explained by an increase of the incidence and mortality of vascular lesions affecting the central nervous system among patients, which has actually inflated the proportion by nearly 10 percent during the period covered by this study. While malignant neoplasms rank fourth as a cause of death in the mental hospitals as compared with second in the general population, the crude death rate for this cause among mental patients is greater than that in the general population. Pneumonia, which has become increasingly unimportant as a cause of death in the general population, is still one of the most frequent causes of patient deaths. The concentration of deaths among a few leading causes was much greater

for the hospital population than for general communities.

Table 7 provides the standardized cause-specific death rates per 100,000 of each of the hospital and general populations by sex.

There has been a steady, and general, decline in the importance of tuberculosis as a leading cause of death, although it has consistently maintained a much greater importance in the hospital population. To be specific, the death rate in hospitals dropped from 293.4 to 116.2 in the course of 5 years, while in communities it declined from 27.2 to 11.1. In general, the mortality rate of this disease was considerably higher for men than for women. However, the rate difference between the two sexes was not as distinct in the hospital population as in the general population. Syphilis and its sequelae were relatively unimportant as a cause of death in both populations, but while the rate declined from 10.5 to 2.9 in the general population, there was a rise from 26.9 to 40.4 among the patients during the 5-year period. This is explained by a sharp rise in mortality from this disease in aged patients, particularly among older male patients.

¹ See table 6 for full title of cause. ² Michigan 1910 population used as standard. ³ Rates standardized for age and sex. ⁴ Rates standardized for age.

The mortality rate for malignant neoplasms was generally higher in the hospitals than in the general communities, but the difference was not particularly remarkable. For example, the rate differential was 339.1 to 202.0 in 1950 and 368.7 to 222.2 in 1954. It is noted that while more men than women were dying from cancer in the general population during the entire quinquennium, the opposite pattern was developing toward the end of the period in the hospital population where female patients finally exceeded male patients in mortality rates from this disease. This increase in the importance of cancer as a cause of death among female patients seems worth special attention. The death rate for women in the 35-64 age group decreased fairly steadily in general communities, but rose rapidly in the mental hospitals' female population. In the general population there was an extraordinarily high cancer mortality rate for the aged group. It should be noted that the death rate for the general population not only exceeded that for the patient population, but also increased rapidly during the course of 5 years.

Diabetes mellitus is the one cause of death studied which was considerably more prevalent in the general population than inside the hospitals. For instance, the rates were 34.0 and 10.8 respectively in 1950. This difference was clearer and more consistent for the old age group. However, during the period of the study, the hospital death rate from diabetes showed a gradual rise from 10.8 to 35.4 which seems to be indicative of an increasing importance of this disease among mental patients. This increasing trend was almost exclusively accounted for by the female patients, particularly those in the older group.

Vascular lesions affecting the central nervous system caused a high mortality in both populations, although the mental hospitals had much higher rates than the communities, regardless of age and sex differences. During the quinquennium there was a very conspicuous rise in this disease as a cause of death in the hospital population, an increase in the rate from 656.7 to 1,146.4, but the rate remained relatively stable at the level of 150 in general communities.

Arteriosclerotic and degenerative heart disease was the most outstanding cause of death

commonly found in both populations. In 1950 the rate was 2,616.1 in hospitals and 372.1 in the general population. While there was a rising trend of the mortality from heart disease in the general population, there was a consistent and favorable decrease in the mortality from the same disease in the mental hospitals, particularly among female patients. The excess of male mortality over female mortality from heart disease was a common phenomenon. However, this characteristic was found to be much more distinct in the hospital population than in the general population.

Mortality rates from hypertension with and without heart disease were about twice as high in the hospital population as in the general community. For instance, in 1954 the rates were 116.2 and 65.9 respectively. It is notable that in the community population relatively more women than men were dying from hypertension, particularly in the older age group. In mental hospitals, on the other hand, there was a consistent and rapidly growing trend in mortality from hypertension during the first few years of the period.

It has been mentioned previously that the sharpest difference in mortality rates between the two populations was from pneumonia. On the 5-year average the rate difference was indicated by as high a ratio as 20 to well over 1,000. However, there has been a steady decline in the death rate from pneumonia in the hospital mortality tables, while the mortality in the general population has remained relatively stationary. This is probably a reflection of the improvement in the general medical care of patients in mental institutions.

Cirrhosis of liver was one of the much less important causes of death in both populations. In 1954 only 20.2 and 15.1 persons died of this disease in mental hospitals and general communities respectively. It is also indicated that neither environmental differences nor the differences in demographic characteristics seem to produce an appreciable variance in the mortality from this disease.

A steady decline in the death rate from nephritis and nephrosis was experienced both in the general population and in the mental hospitals, but this trend was much more markedly observed in the latter, where the rate changed

from 166.9 to 30.3, than in the former, where it changed only from 22.4 to 16.1.

Suicide and self-inflicted injury was a much more common cause of death in mental hospitals at the beginning of the quinquennium. The actual rate difference was 43.1 to 16.3 in 1950. However, the death rate difference became almost negligible toward the end of the period as the patient deaths from this cause gradually declined. This was almost entirely due to a decrease in suicide among male patients, in which group the death rate actually dropped to less than one-third of the 1950 record. Thus, at the end of the quinquennium, the death rate for men in the general community became considerably higher than that for men in the hospital population. Suicide and self-inflicted injury was a much more prevalent cause of death among people in the productive ages than those in other ages.

The accidental death rate was much lower in the hospital population than in the general population. In 1950, for instance, there were 26.9 per 100,000 accidental deaths in hospitals while 77.1, or three times as many, deaths per 100,000 were caused by accidents outside hospitals. However, there was a general rising trend in the mortality among patients, particularly among female patients.

Standardized Cause-Specific Rates

Having eliminated the influence of age-sex composition of a population, the standardized 5-year average rates provide a better basis for comparison of the mortality from specific causes between hospital and general populations, as well as between men and women of each population. The standardized cause-specific death rates for each of the two populations are ranked in the following order:

Hospital

- | | |
|--|--------------------------------------|
| 1. Arteriosclerotic and degenerative heart disease | 7. Nephritis and nephrosis |
| 2. Pneumonia | 8. Suicide and self-inflicted injury |
| 3. Vascular lesions | 9. Accident |
| 4. Tuberculosis | 10. Cirrhosis of liver |
| 5. Malignant neoplasms | 11. Syphilis |
| 6. Hypertension | 12. Diabetes mellitus |

General

- | | |
|--|---------------------------------------|
| 1. Arteriosclerotic and degenerative heart disease | 7. Pneumonia |
| 2. Malignant neoplasms | 8. Nephritis and nephrosis |
| 3. Vascular lesions | 9. Tuberculosis |
| 4. Accident | 10. Suicide and self-inflicted injury |
| 5. Hypertension | 11. Cirrhosis of liver |
| 6. Diabetes mellitus | 12. Syphilis |

The death rates from two different causes, pneumonia and tuberculosis, showed a marked difference between the two populations. The age-sex adjusted rate from pneumonia was approximately 30 times as high in the hospital as in the general population, while the rate from tuberculosis was 13 times as high in the hospital as in the general population. The adjusted rate from heart disease, vascular lesions, hypertension, nephritis and nephrosis, suicide, and syphilis was about twice as high for the patients as for the people in the community. Conversely, cancer, accident, diabetes mellitus, and cirrhosis of liver were found to be less important among the patients.

The data further indicate that the spread between highest and lowest cause-specific death rates was much smaller for the general population than for the hospital population. The adjusted mortality rates were always higher for men than for women excluding diabetes mellitus in both places, cirrhosis of liver in the hospital, and hypertension in the community.

Rates by Psychiatric Diagnosis

Of somewhat different significance from the cause-specific death rate was the death rate as it relates to psychiatric diagnosis. The diagnosis-specific rate is measured as the number of patient deaths with a given psychiatric diagnosis per 1,000 patients with the same diagnosis. The number and percentage distribution of resident patients and deaths by diagnosis (7) and sex and the diagnosis-specific death rates for 1955 are presented in table 8. (Because of the availability of data, 1955 was used for the data analyzed in table 8. Death rates computed in this table can be treated as proportions amenable to the statistical test for the significance of the difference. However, in view of small numbers in some diagnostic categories, the sampling distribution of the difference between

proportions may not approximate normality.)

Diagnostic groupings in this study were developed to provide homogeneity of categories and also to use the experience in hospitals which has indicated meaningful subgroups. Since the mortality data were not available by age and sex for each diagnosis, the following discussions are based upon the crude death rates without control for the age-sex variation of the patient groups with different diagnoses.

More than 80 percent of the 20,376 patients residing in State mental hospitals in 1955 were included in three diagnostic classes, with 57.9 percent diagnosed as schizophrenic; 13.2 percent diagnosed as chronic brain disorders; and 11.1 percent diagnosed as disorders of the senium. The degree of concentration just mentioned was found to be somewhat higher among male patients than among female patients, although a considerably larger proportion, 61.0 percent, of female patients than of male patients, 54.5 percent, belonged to the schizophrenic group. There were about twice as many males as females with chronic brain disorders.

The pattern of diagnosis-specific death rates appeared to be quite different from that of cause-specific death rates. First, the range between highest and lowest rates by diagnosis was found to be much smaller than that by cause of death. Second, resident patients can easily be dichotomized, in terms of crude death rate, into the high- and the low-risk groups respectively. The high-risk groups for both sexes consisted of those with disorders of the senium and those with acute brain disorders. This was also true when female patients were considered individually, but when male patients were so considered, those with disorders of the senium and those with involuntional psychoses actually constituted the high-risk group. Within the low-risk group the variation of death rate was not great.

The highest death rate, 360.9 per 1,000 was found for the group of patients having a diagnosis commonly associated with advanced age, that is, disorders of the senium. The second highest, 131.0 per 1,000, was for the group with acute brain disorders, but when male patients were considered separately the group with involuntional psychoses ranked second highest,

Table 9. Mean age of resident patients, by diagnosis and sex, 1955

Diagnosis	Mean age and sex		
	Both sexes	Male	Female
Acute brain disorder.....	56.3	56.5	55.8
Chronic brain disorder.....	54.3	54.5	54.0
Disorders of the senium.....	75.4	73.8	76.8
Involuntary psychoses.....	63.2	64.5	62.6
Manic-depressive psychoses.....	62.0	62.5	61.7
Schizophrenia.....	49.1	48.4	49.6
Psychoneurotic disorders.....	51.4	45.2	55.8
Personality disorders.....	44.8	44.8	44.8
All others.....	53.8	52.4	55.3
Total.....	56.7	55.8	57.4

141.8 per 1,000. For other diagnostic groups used in this analysis the rates were always less than 100 and ranked in the following order: chronic brain disorders, involuntary psychoses, manic-depressive psychoses, psychoneurotic disorders, all others, personality disorders, and schizophrenia. The psychotic group with relatively low death rates were those with the so-called functional disorders without known physical basis. For example, the schizophrenic group had the lowest death rate, 21.4 per 1,000, regardless of sex difference. As against the usual pattern, relatively more female patients than male patients diagnosed as either chronic

brain disorders, manic-depressive psychoses, or personality disorders died in 1955.

Physical Condition, Age, and Diagnosis

While the physical condition of a patient on admission cannot be assumed to remain constant during hospitalization, it still is the best available estimate of the importance of physical explanations for the generally high mortality rate of psychiatric patients. The information is provided by the admitting physician and is classified as "good," "fair," "poor," or "critical."

The mean age of resident patients by diagnosis and sex, and the physical condition of patients on admission by diagnosis, were examined together to account for some of the basic differences in the diagnosis-specific mortality rate (tables 9 and 10). Spearman's rank order correlation (8) between diagnosis-specific death rate and percentage of patients with "good" physical condition on admission substantiates a significant relationship between them ($r_s = -0.900$; $P < 0.001$). That is, the greater the percentage of patients with "good" physical condition the lower the death rate. An extremely high death rate for the senile psychoses was well supported by the fact that not only the mean age of this group was high but also a large proportion of the group had a "subnormal" physical condition on admission

Table 10. Percentage distribution of all admissions and admissions for selected age group, by diagnosis, and percentage distribution of admissions for selected disorder, by patients' physical condition, 1955

Diagnosis	All ages ¹	Age group			Physical condition				
		20-44	45-64	65 and over	Total ¹	Good	Fair	Poor	Critical
Acute brain disorders.....	1.8	2.3	2.2	0.5	100.0	58.4	28.6	10.4	2.6
Chronic brain disorders.....	10.0	7.0	18.1	6.8	100.0	29.4	47.7	18.2	4.7
Disorders of the senium.....	20.4	.1	10.6	80.4	100.0	14.8	35.2	38.9	11.1
Involuntary psychoses.....	3.7	.3	12.0	1.6	100.0	61.5	33.5	3.7	1.3
Manic-depressive psychoses.....	4.0	2.6	7.5	3.4	100.0	53.8	40.4	5.3	.5
Schizophrenia.....	42.2	65.2	32.8	4.5	100.0	74.5	21.4	3.6	.5
Psychoneurotic disorders.....	4.5	5.8	4.0	1.7	100.0	70.8	25.1	4.1	0
Personality disorders.....	11.6	14.4	11.1	1.0	100.0	75.5	22.1	2.0	.4
All other.....	1.8	2.3	1.7	.1	100.0	71.4	19.5	7.8	1.3
Total.....	100.0	100.0	100.0	100.0	100.0	56.1	28.4	12.4	3.1

¹ Including 19 and under.

NOTE: Because of the availability of data, 1955 was used for analysis.

identified as either "fair," "poor," or "critical." For example, 11.1 percent of those with disorders of the senium were identified as "critical" at the time of admission to the hospitals.

In contrast, the lower mortality rates for the schizophrenic group and for the group with personality disorders can be explained by the low mean age of each group and also by "good" physical condition of those patients on admission. The relatively high death rates in the diagnostic categories of acute brain disorders, chronic brain disorders, disorders of the senium, involutional psychoses, and manic-depressive psychoses coincide remarkably with the fact that each of these groups had a relatively high mean age as well as a relatively large proportion with "subnormal" physical condition at the time of admission.

It should be noted that as high as 43.9 percent of all patients admitted to State mental hospitals in 1955 were physically identified as either "fair," "poor," or "critical." This seems to be one of the most significant factors explaining the high mortality rate in mental hospitals as compared with the low mortality rate prevalent in the general communities.

The physical condition of the patient on admission was found to be closely related to the patient's age on admission. That is, the higher the age of the patient group the smaller the proportion having "good" physical condition. Spearman's rank correlation coefficient ($r_s = -0.835$; $0.01 > P > 0.001$) supports this generalization. The patient group between the ages of 20 and 44 at the time of admission had 75.7 percent classified as in "good" physical condition while only 17.3 percent of the patients aged 65 and over at the time of admission were so classified.

Summary and Conclusion

The interpretations and generalizations presented in the present study are based on data collected in Michigan for the 1950-54 period. The following conclusions appear to be of significance.

1. The mental hospital population was over-represented by the middle and old age groups as compared with the State population.

2. The hospital mortality rate was more var-

iable and unstable than the general mortality rate.

3. In terms of crude rate the overall hospital mortality was 6.8 times as high as the overall general mortality.

4. When the rates were adjusted for age and sex, the overall hospital mortality was 3.6 times as high as the overall general mortality.

5. The quinquennial decline in the death rate was much greater in the hospital population than in the general population, thus narrowing the rate discrepancy between the two.

6. The quinquennial decline in the death rate was much greater among older people, particularly among older men, in both populations.

7. The sex difference in death rate was much greater in the hospital population than in the general population.

8. The hospital death rate was always higher than the general death rate in each age-sex specific group.

9. The relative importance of each of the 12 leading causes of death was manifested differently in the two different populations. The two most frequent causes of death in the hospital population were arteriosclerotic and degenerative heart disease and pneumonia, while those in the general population were arteriosclerotic and degenerative heart disease and malignant neoplasms.

10. The age-sex adjusted mortality rates from pneumonia and tuberculosis were approximately 30 times and 13 times as high in the hospital as in the general population respectively.

11. Malignant neoplasms, accidents, cirrhosis of liver, and diabetes mellitus were found to be less important for the hospital population than for the general population.

12. The high mortality group of the patients consisted of those with senile psychoses and those with acute brain disorders.

13. The psychotic group with relatively low death rates were those with functional disorders such as schizophrenia.

14. A statistical analysis substantiated a consistent, positive relationship among death rate, patient age, and the proportion of patients with "subnormal" physical condition on admission to the hospital.

Although the present investigation is largely descriptive in nature, it is hoped that the results

will have not only heuristic value but will also be productive of a series of hypotheses in regard to the dynamics of differential mortality among hospitalized psychiatric patients.

DOCUMENTATION NOTE

An additional table showing the cause-specific death rate per 100,000 for hospital and general populations, by sex, for the 5 years 1950-54, has been deposited as document No. 5565 with the American Documentation Institute Auxiliary Publications Project, Photoduplication Service, Library of Congress, Washington 25, D. C. A photoprint may be obtained by remitting \$1.25; a 35-mm. microfilm copy by remitting \$1.25. Advance payment is required. Cite document number. Make check or money order payable to Chief, Photoduplication Service, Library of Congress.

Syphilis Serology Courses

Eight laboratory courses will be offered at the Venereal Disease Research Laboratory of the Public Health Service in Chamblee, Ga., September 1958 through May 1959, according to the following schedule:

Serology of syphilis. September 8-19; December 1-12; February 9-20; April 6-17.

Tests for syphilis using treponemal antigens. October 6-17; March 9-20.

Fluorescent antibody techniques in the diagnosis of the venereal diseases. March 23-27.

Control of syphilis serology by the regional laboratory. May 4-15.

The four refresher courses in serology of syphilis will consist of lecture, demonstration, and participation periods covering the most widely used nontreponemal procedures in addition to supplemental methods. Special reference will be made to the latest developments, such as the Kolmer test with Reiter protein antigen, the TPCF test, and the use of a stabilized antigen emulsion in the VDRL tests.

The two courses in the treponemal antigen tests for syphilis are designed for senior staff members. The course in fluorescent antibody

techniques will cover the performance of the fluorescent treponemal antibody test, with instruction in the use of ultraviolet microscope assemblies. Instruction in the identification of *Neisseria gonorrhea* and *Haemophilus ducreyi* will include antibody preparation, fluorescein-labeling, and preservation. The course in control of syphilis serology by the regional laboratory, designed for laboratory directors and senior staff members, includes review of national and statewide serologic evaluation programs, laboratory visits, and field workshop procedures, together with discussion and demonstration of new procedures.

Applications must be approved by a State health officer or State laboratory director, by the medical officer in charge or a Federal agency, or by the organization sponsoring applicants from other countries. Application forms may be obtained from: Director, Venereal Disease Research Laboratory, Venereal Disease Branch, Communicable Disease Center, Public Health Service, P. O. Box 185, Chamblee, Ga.

The Nurse in the U. S. Public Health Service

PHS Publication No. 361. Revised September 1957. 24 pages, plus supplement; illustrated.

The story of career opportunities for both clinical and public health nurses in the various nursing programs of the Public Health Service is brought up to date. The booklet describes the work of nurses in Service hospitals, at the Clinical Center of the National Institutes of Health, in Indian health and international health programs, in field research and investigation, in work with States, and in nursing resources activities.

The two personnel systems of the Service, Civil Service and Commissioned Corps, are explained, and methods of applying for various assignments are outlined. A supplement lists requirements for applicants and other detailed employment information.

Patients in Public Hospitals for the Care of the Mentally Ill, 1956-1957

PHS Publication. Mental Health Statistics. Current Reports Series MHB-H-3. December 1957. 8 pages. 5 cents.

Designed to permit early publication of selected statistics for public mental hospital systems in the United States, this report replaces the publications entitled "Patients in Public Hospitals for the Prolonged Care of the Mentally Ill," formerly published in this series, and "Mental Patient Data for Fiscal Year," previously presented in *Public Health Reports*.

Data from two sources are combined. Statistics for 1956 are based on preliminary tabulations of schedules submitted for the 1956 census of mental patients. Those for 1957 are based on estimates obtained in

a special survey of public mental hospitals conducted shortly after the close of the fiscal year. Selected items of patient movement, number of employees at end of year, and maintenance expenditures are shown for each State, with a separation into "all public hospitals" and "prolonged care" for those States having short-term psychopathic hospitals.

National Library of Medicine

PHS Publication No. 507. Revised February 1958. 13 pages.

Library hours, loan procedures, photographic and reference services, translators, history of medicine division, art section, medical motion picture collection, and publications of the National Library of Medicine are described in this booklet.

Uniform Definitions of Home Accidents

PHS Publication No. 577. 1958. 15 pages. 30 cents.

Designed to provide precise meanings of terms in the home accident field, this manual of definitions should prove useful to all personnel engaged in home accident reporting or home accident prevention programs.

To be listed a term must be pertinent to home accident prevention; it must have a special connotation in home accident prevention or a related field (medicine, statistical analysis, engineering, and so forth); and, it should, if possible, indicate a measurable variable. Certain common terms which are subject to misinterpretation are included, but clearly defined common or nontechnical terms found in the average dictionary are omitted.

The definitions were developed by the Conference on Uniform Defini-

tions of Home Accidents that met in Chicago, April 1957, under the sponsorship of the Public Health Service, the American Public Health Association, and the National Safety Council.

Taking Care of Diabetes

PHS Publication No. 567. 1958. 32 pages; illustrated. 20 cents.

Written especially to help the diabetic person and his family develop a better understanding of the disease and its control, this booklet presents salient facts about the physiology of diabetes and the relation of food, exercise, and insulin to its control.

The patient is shown how he can have a wide variety of foods by using the meal plan suggested by his doctor in conjunction with six food exchange lists. The technique used in administering insulin, how to take proper care of injection equipment, and Benedict's test for urine sugar are described.

Emphasis is given to the importance of recognizing symptoms of insulin reaction and onset of diabetic coma as well as the need for the diabetic patient to take proper care of his feet.

Manual for Nutrition Surveys

Interdepartmental Committee on Nutrition for National Defense. 1957. 160 pages. \$1.50.

Methods for conducting nutrition surveys and appraising the nutritional status of a population are presented in this reference and guide. Although the manual is designed primarily for surveys of military forces, the basic approach and methodology are applicable to civilian populations.

The manual is intended to establish uniform methods in collecting data, to provide a reference to insure maximum coverage of the essential facts, and to serve as a guide for interpretation of dietary, biochemical, and clinical data. It also offers guidelines in defining the duties of

various team members and for training local personnel.

The list of necessary supplies and equipment and the chapter on sampling are applicable equally to a single nutrition survey or a permanent nutrition service.

State Personnel in Official and Voluntary Agencies Concerned With Agricultural Migrants

PHS Publication (unnumbered). 1958. 1½ pages.

Persons in selected official and voluntary agencies in the States who are officially designated to be contacted on questions regarding agricultural migrants are identified. Representatives of State departments of health and education, the Farm Placement Service of the U. S. Department of Labor, and the Migrant Ministry of the Home Missions Division of the National Council of Churches are listed along with persons named by the governors as liaison with the President's Committee on Migratory Labor in States where there is no official committee.

Copies can be obtained from: Division of General Health Services, Bureau of State Services, Public Health Service, Washington 25, D. C.

Public Exposure to Ionizing Radiations

What Public Health Personnel Need to Know

American Public Health Association. 1958. 55 pages; glossary. \$1.35; orders for 25 or more at a discount.

This pamphlet aims to provide public health employees with simple concepts basic to a radiological health program. The text presents the issues, in perspective. Although it does not deal with physics or with the precise definition or measurement of radiations, it describes the phenomena of radiations and their probable public health effects. Major sources of radiation of concern to public health workers are discussed

as to their benefits and hazards, present and future.

The pamphlet was prepared by a committee of the American Public Health Association with advice and technical assistance from employees of the Public Health Service. Orders should be placed with the American Public Health Association, 1790 Broadway, New York 19, N. Y.

Research and Education in Rheumatic Diseases

Transactions of the Second National Conference

Arthritis and Rheumatism Foundation and the National Institute of Arthritis and Metabolic Diseases of the Public Health Service. 1957. 156 pages.

Texts of papers presented at the conference are assembled in this book under three headings: basic disciplines and promising pathways in research in rheumatic diseases, support currently available for research and training in rheumatic diseases, and the United States Public Health Service graduate training program in arthritis.

Distribution of the publication, now completed, is limited to members of the participating associations, medical libraries, medical schools, and a selected list of rheumatologists. Inquiries concerning availability should be addressed to the Information Office, National Institute of Arthritis and Metabolic Diseases, Public Health Service, Bethesda 14, Md.

Health Statistics From the U. S. National Health Survey

Origin and Program

PHS Publication No. 581-A1. 1958. 36 pages. 30 cents.

Background information on the U. S. National Health Survey, including history, need for health statistics, policies, and program, is presented in this booklet. It is the first

of a series (series A) covering technical and methodological matters relating to the survey.

Appendixes contain the text of the National Health Survey Act (Public Law 652, 84th Congress) and a reprint of recommendations for collection of health data of a subcommittee of the U. S. National Committee on Vital and Health Statistics (PHS Publication No. 333, 1953).

Health Statistics From the U. S. National Health Survey

Preliminary Report on Number of Persons Injured, United States, July-December 1957

PHS Publication No. 584-B3. 1958. 32 pages. 30 cents.

Persons sustaining injuries that caused restriction of their usual activities for at least a day or who were medically attended are included in the estimates. The report contains 26 detailed tables, text tables, and charts presenting breakdowns by age, sex, urban-rural residence, and class of accident. Data are based on nationwide household interviews of a representative sample of the population.

Appendixes provide technical notes on methods and definitions.

Digest of Prepaid Dental Care Plans, 1958

PHS Publication No. 585. 1958. By Walter J. Pelton and Richard W. Bowman. 41 pages.

All known prepaid dental care plans operating in the United States are listed by name, with address, sponsorship, date established, geographic area served, eligibility requirements, and size of enrollment. Information on methods of operation and types of benefits offered is also included.

The plans are grouped into two major categories, plans with regular benefits and those with limited benefits, and are subdivided into four groups: communitywide, union spon-

sorship, employer-employee sponsorship, and fraternal organization sponsorship. The complete dental fee schedules of four of the most comprehensive plans are reproduced in the appendix.

Tuberculosis Beds in Hospitals and Sanatoria, May 1, 1957

PHS Publication No. 518. 1958. By Stanley Glaser and Josephine Johnston. 41 pages. 30 cents.

A listing by State and city, as well as alphabetically, of hospitals and sanatoria in the United States and Territories with five or more beds available for treating patients with tuberculosis is provided. Included are all State, local, private, and Federal institutions except Federal mental and penal institutions. Type of ownership is specified.

Homemaker and Related Services

A Directory of Agencies in the United States

PHS Publication No. 598. 1958. 75 pages.

Name, location, telephone number, type of agency, area served, kind of service provided, year established, number of homemakers employed, and number of families served during a 1-week period are listed.

The directory was compiled from a nationwide survey of homemaker services by the Public Health Service in cooperation with the Children's Bureau and the Bureau of Public Assistance, Social Security Administration.

Strike Back at Stroke

PHS Publication No. 596. 1958. 37 pages; illustrated. 40 cents.

Step-by-step instructions and illustrations are given for 21 therapeutic exercises developed by experts in the field of medical rehabilitative therapy. The booklet also

contains information on how to fix the bed for the patient, how to place the patient in bed, and what to do if the patient cannot speak.

Designed to make it easier for the doctor to show what can be done for and by the stroke victim at home to help minimize the disability that usually follows a stroke, the manual even contains a prescription blank printed below each exercise so that the doctor can specify the frequency and duration of selected exercises.

The Vending of Food and Beverages

PHS Publication No. 546. 1957. 18 pages. 15 cents.

Intended for adoption by municipalities and States, the suggested sanitation ordinance and code contains the recommendations of the Public Health Service. It is published for the guidance of jurisdictions desiring a uniform law based on the best information currently available. The format of the ordinance permits flexibility in adoption or enactment.

The recommendations are based on field studies of current practices in vending machine design, construction, and operation, and a review of existing State and local regulations. They were developed at the request of State and local health authorities and the vending machine industry.

Proceedings of Symposium on Coccidioidomycosis, 1957

PHS Publication No. 575. 1957. 197 pages; illustrated.

Currently available information on the epidemiology, ecology, immunology, pathology, diagnosis, and treatment of coccidioidomycosis, together with the most recent advances in research, is comprehensively reviewed. This material is published for the benefit of investigators everywhere who are attempting to overcome the difficulties in diagnosing, controlling, and treating this disease.

Directory of Medical and Biological Research Institutes of the U. S. S. R.

PHS Publication No. 587. 1958. 340 pages.

More than 700 biological and medical research institutes in the U. S. S. R., with their subdivisions and laboratories, are listed in this directory. Arrangement is geographic, with a subject index. A name index includes more than 1,500 Russian scientists.

The directory is intended as a guide not only for those planning scientific visits or correspondence but also for those studying Soviet medical research.

Extent of Cancer Illness in the United States

PHS Publication No. 547. 1958. 23 pages. 25 cents.

Trends and variation in cancer mortality and incidence, some aspects of diagnosis and treatment, and survival prospects for cancer patients are covered in this well-documented, statistical study of cancer. The booklet is comprised of 31 questions and answers together with 22 charts and 9 tables. It is directed to persons concerned with the course of cancer in individual patients or with its impact on larger population groups.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared by other Federal agencies.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

the Hospital

as a Community Health Center

EDWIN L. CROSBY, M.D., Dr.P.H.

Following is the Wilinsky Lecture, delivered at the Harvard School of Public Health, Boston, on October 14, 1957. The Charles F. Wilinsky Lecture Fund was established in 1954 to endow lectures on the role of the hospital in public health. Dr. Wilinsky served as executive director of Beth Israel Hospital in Boston and deputy health commissioner of that city. He is a former president of both the American Public Health Association and the American Hospital Association.

THE HOSPITAL is a dynamic, not a static, institution. Looking at our hospitals in the context of American life and medical and scientific progress, we know that a revolution in hospital care is under way. In the words of Dr. James Mackintosh, emeritus professor of public health, School of Tropical Hygiene and Public Health, University of London, "It is exciting to live in a revolution; it is tragic not to realize it."

A little more than a half century ago it seemed that we'd gone about as far as we could. Then science exploded into medicine and almost overnight there was a whole galaxy of new treatment techniques, new equipment, and

Dr. Crosby is the director and a former president of the American Hospital Association. He served as director of Johns Hopkins Hospital, Baltimore, Md., from 1945 to 1952, and as director of the Joint Commission on Accreditation of Hospitals from 1952 to 1954. In 1950 he was the United States representative on the Expert Subcommittee on Hospital Statistics of the World Health Organization.

new and different personnel. Even professional workers in the health field must be astounded by the many new scientific developments which have changed hospital and health care in the last two generations. This period has been marked by the development of roentgenology; advances in the science of nutrition, including the discovery of vitamins; elimination of most of the infectious diseases through immunization, better control, and good public health practice; the control of diabetes with insulin; the discovery of the antibiotics; the medical use of radionuclides; new anesthetics making possible amazing surgical procedures; the use of human blood and its fractions; and so many other giant feats that I cannot possibly mention them all. During this period, medical thought broadened to see the individual as a physical and emotional whole. As Francis Peabody said, "What is spoken of as a clinical picture is not just a photograph of a man in bed; it is an impressionistic painting of the patient surrounded by his home, his work, his relations, his joys, sorrows, hopes and fears" (1).

In addition to the effect of new techniques in health care, hospitals have also felt the impact of dramatic social and economic developments in the United States. Our population is growing; we are now a nation of some 170 million, and by 1967 if the present rate of increase continues, we may well have a population of almost 200 million. There is a continuing increase in the proportions in our population of the elderly and of the very young, although we

are often inclined to overlook the proportionate increase of the very young.

Through our fine educational system, through the various medical, hospital, and public health organizations, and through the work of public information media, this vast American public is growing in knowledge about health services and becoming increasingly appreciative of the value of health. Good health care has become part of the increasingly higher standard of living which more Americans can now afford. The improving economic conditions of the last two decades have been accompanied by new concepts of the responsibility of employers, unions, and government at all levels for maintaining health.

As a result of this growth in numbers and in understanding of health care, the utilization of hospitals has risen rapidly. From 1946 to 1956 the number of admissions to all hospitals increased 41 percent, and admissions to nonprofit, short-term hospitals, the community hospitals, increased 54 percent. This increased use of hospitals is not due solely to increased population. In 1946, there were 112 admissions per 1,000 population to all hospitals, and in 1956 there were 132 admissions per 1,000 (2).

Meanwhile, the financial problems of hospitals have changed too. The costs of new buildings and of renovating old hospital facilities have been rising. Voluntary hospitals are no longer simply philanthropic institutions supported by private donations. Hospitals today are dependent on fees from patients or third parties such as Blue Cross, insurance companies, and public welfare agencies. Increased costs of operation have forced them to become business organizations. They are concerned with balancing budgets and defining the full cost of services in order to collect from the patient, or in his behalf, the amounts necessary to sustain the hospital's operations.

Thanks to the growth of prepayment, the hospital as an economic organism is now more stable than ever before. But the public has yet to fully realize the dollar cost of health care. People want the best in health care. It must be paid for, in one way or another. Hospital and other workers in the health field must support the idea that people should set aside enough from their current income to enable them to pay

for the best of care. We are responsible for seeing that they get a full dollar's worth of care for every dollar spent.

We in hospital careers feel the impact of revolutionary medical and social advances, and we are doing our best not only to adapt to them but also to advance hospital care as rapidly as possible.

Hospitals and Public Health

I would like to discuss one important aspect of hospital care, the hospital as a community health center. The community's investment in the hospital can best be realized when hospitals and public health authorities work together with the medical profession as partners in the teaching and practice of preventive medicine and public health. The relationship between the hospital and the public health profession has been, and continues to be, an important area for study, discussion, and action.

However, I would like to consider the hospital's contribution to the health of the public in a wider context; to describe some ways in which the hospital may serve its community; and finally, to discuss ways in which the public, through the hospital, may help improve the public health.

For many years, the hospital was virtually an island of curative medicine. To be sure, many hospitals thus insulated did a remarkably good job of serving their communities. But just as the practitioner of medicine can no longer limit his tools to his black bag, the average hospital today cannot offer the best care while limiting its resources to the skills found within its walls. If the hospital lives as an island in the community, concerned only with the patients who pass through its doors, not thinking whence they come or where they go, it is an incomplete public servant; it does not fully meet public demands.

I have heard Dr. Mackintosh say that while the function of hospitals today is "to care for the sick, in the future their function will be not to care for the sick, but rather the well." He emphasizes, and I agree with him, that its public health responsibility is one of the major functions of the hospital. In his words, "The good hospital acts as an intelligence service

sending out, as necessary, danger warnings for the protection of the public. Its function is to watch the movement of sickness, to act early and with dispatch before great harm is done. . . . Sickness is an incident in the life of an individual, but to the hospital and its staff, sickness is a challenge, a focus of enquiry from which prevention should radiate as well as cure." As early as 1936, the Committee on Public Health Relations of the American Hospital Association, of which Dr. Wilinsky was chairman, stated that newer conceptions of an adequate community health program emphasize "the gradual disappearance of the line of demarcation between the prevention and the treatment of disease" (3).

In fact, preventive medicine has long been a joint responsibility of the hospital and health departments. The hospital assists the work of the health department by deeds such as registering births and deaths; detecting and reporting communicable diseases; treating patients with tuberculosis and poliomyelitis; and continuing the never-ending fight against infection, a fight recently dramatized by the appearance of resistant strains of *Staphylococcus aureus*. The health department, especially in rural areas, may use the laboratory and other clinical facilities of the hospital. The hospital practices the principles of maternal, infant, and child hygiene, and tries to educate the patient and his family in these and other matters of health and hygiene.

The Ford Foundation reports that many hospitals used part of their foundation grant to improve educational facilities for the communities they serve; that they organized educational programs on such aspects of preventive medicine as maternal and child care, sex education, nutrition, mental hygiene, and early detection of serious diseases; and that their social service and outpatient departments "combine treatment with instruction in solving family health problems" (4). In the outpatient work of the hospital, cooperation between the health department and the hospital is closest. As the patient leaves the hospital, he is followed by the health department, which sees that the hospital's achievements are not lost and that he is restored to the greatest possible self-reliance.

Hospitals are also working out other new programs to extend their services to their communities. Individual hospitals and hospital associations are undertaking research in management aimed at expanding the hospital's responsibilities in community health protection. Subjects of such studies have included the planning of the hospital's physical plant, the improvement of food service, the possibility of organizing regional cooperation between large and small hospitals, and the development of new programs of outpatient and home care.

In another expansion of their service to their communities, hospitals are extending their emergency responsibilities beyond that of routine service in disaster planning: the resourceful organization of emergency equipment and procedures to save lives when natural or mechanical catastrophes engulf numbers of people. To be ready for communitywide emergency situations—whether fire, flood, tornado, or train or plane crash—hospitals are cooperating in planning with public health, civil defense, and other community agencies.

Another hospital activity, no longer new but of the utmost importance, is the voluntary program of hospital accreditation. Accreditation means that the quality of patient care in the hospital meets adequate standards. It is a stamp of approval conferred by the Joint Commission on Accreditation of Hospitals, an independent group formed in 1952. The public is becoming aware of the distinction between accredited and nonaccredited hospitals; the hospital which requests a survey and achieves accredited status, or is earnestly working toward that goal, vouches to the community that it is serving its best interests. Accreditation is a voluntary program of continued self-inspection, the strongest arm of freedom of medicine and hospitals. Through accreditation, hospitals indicate to their communities that with independence in a free society goes the responsibility to measure up to society's demands. National recognition that hospitals are striving to improve their services is indicated by the recent Ford Foundation grant to establish voluntary counseling service to help hospitals improve their administrative services and, as a result, their patient care.

Extending Services

Four aspects of extending the hospitals' services into the community seem to me especially adventurous and important: planned cooperation between large and small hospitals, new rehabilitation programs, new types of care for the chronically ill, and new concepts of outpatient care.

We still need more precise definition of the elements of institutional care of the sick. Such definition would lead to more effective and economical care. The community hospital of the future will not stand alone, but must be linked in some organized way with other institutions. With such a link difficult problems can easily be referred to centers with more specialized facilities, and the staffs of outlying institutions can benefit regularly by visits from specialists from the more central and highly developed hospitals. Every community should have a carefully developed plan for orderly integration between health and welfare agencies and the various institutions offering health services.

I would make three suggestions to guide planning. First, the community plan must assure that each patient is treated in the type of institution that his condition requires. Second, we must organize professional disciplines and physical equipment to focus on special treatment problems, grouping patients according to need and where care can best be given. Third, patient transfer is a two-way street. We must move toward broader acceptance of transfer of patients from small hospitals to large medical centers as patient care dictates. And conversely, we must arrange for movement of patients from general hospitals to nursing homes, convalescent homes, or home care programs.

Rehabilitation, the second important aspect, is vital in the changing therapeutic picture. I have often thought that almost every patient who enters a hospital is in need of some kind of rehabilitation, whether a brief but encouraging chat, a mild form of special exercise, or, in more seriously disabled cases, intensive physiotherapy and psychotherapy. All members of the hospital staff will need to understand the importance of rehabilitation in the early stages of a patient's illness.

I believe that if we are to bring the benefits of rehabilitation services to communities—including the smaller ones—then the hope for establishing and developing such services rests with the community hospital. A centrally located rehabilitation center may be able to serve the patients of several hospitals in the area. These centers might have not only medical and directly allied facilities but also such services as vocational testing, guidance, and training.

Many hospitals now include rehabilitation among their services, but as Dr. Theodore Klumpp has pointed out, "The hospital is still only a repair shop where broken bodies are sent to be mended" (5). I would agree with him that some day it will also be a maintenance shop where the most intricate mechanism in the world will be sent to find out how it can best be cared for to prevent damage. The development of proper rehabilitation services in a community is one of the greatest challenges facing hospitals.

Problems relating to the illnesses that accompany middle and later life are a third growing concern in the health field. In fact, meeting the challenge offered by our increasing number of aging persons is probably the single greatest problem we face. George Bugbee, president of the Health Information Foundation, has reported that the group over 65 incurs 13.1 percent of all charges for health services although it constitutes only 8.4 percent of the population (6). And the problem will become greater. Today, more than 13 million people are 65 years of age or older, and by 1980, 1 out of every 7 people will be 65 or older, while 2 out of 5 will be 45 or older.

Because much of the illness that hospitals see will be chronic, hospitalization will generally be a relatively short episode in a long course of treatment, and care will have to be continued at home. In the future services provided at home cannot be limited, as they generally have been in the past, to those performed by doctors and nurses. The full range of services now provided only to the hospital inpatient must be properly adapted to home care.

New concepts of outpatient care open a fourth area of expanding hospital service. Along with the other revolutionary trends in hospital care will come the death of the old idea that ambulatory care is only for the poor. Very slowly,

forced by a combination of economics, science, and good old-fashioned common sense, we are accepting the idea of ambulatory service to the whole community. Community hospitals take bed patients of all income groups, and in the future hospitals will probably eliminate financial distinctions among ambulatory patients as well. For both ambulatory and bed patients, it is becoming clearer that prepayment will be the means of paying hospital bills for the self-supporting, while tax funds assist the medically indigent and cover the cost for the indigent.

A major fault in our organizational plans for the care of ill persons has been that the plans seem to encourage patients to lie down in hospital beds in order to be eligible for prepayment benefits. Without the benefit of prepayment it is only natural for people to delay seeking the care they need. In the interest of good community health we must encourage prepayment plans to offer more complete coverage, adding to basic inpatient coverage on a service benefit basis both extended benefits and protection for the ambulatory patient.

Need for Research

In considering regional cooperation, outpatient care, and other new demands upon the hospital, I am repeatedly impressed with the problems of hospital administration and with the urgent need for hospitals to expand research into all phases of their operation. Hospital administration is being recognized as the demanding science and art that it is. With its singular system of relationships among the trustees, medical staff, administrator, other personnel, and volunteers, the hospital, of all institutions that I know, is the most difficult to administer. It is also one of the most satisfying. If the administrator is a skillful manager, he can help the complex health team work better together in the interest of the patients and their community. I predict that hospitals will become even more complex institutions to administer in the years to come. Two reasons for this prediction can be summed up in two words: costs and personnel.

The cost of hospital care has been rising, and there is no denying that it will continue to rise. A well-reasoned but admittedly conservative

estimate made in 1954 was an increase at the rate of 5 percent per year (7). From 1955 to 1956, the increase was 9 percent (2). Providing facilities and personnel for a widening range of services grows more expensive every year. The total expense of the Nation's short-term, non-profit, general hospitals rose 223 percent from 1946 to 1956. Better patient care today means both more skilled personnel to provide new technical services and simply more personnel of all types. In nonprofit, short-term hospitals, our community hospitals, personnel increased from 156 per 100 patients in 1946 to 213 per 100 patients in 1956 (2). No wonder payroll expense cuts the largest chunk from the hospital's budget, more than 60 percent of the total expense of nonprofit, short-term, general hospitals in 1956.

At the same time that the number of personnel has been increasing, the number of hours in the workweek of hospital personnel, like those in offices and factories, has been decreasing. The difference is that the hospital must operate 24 hours a day, 168 hours a week, 52 weeks a year, always ready for any emergency. The shorter workweek has frequently been helpful in attracting additional qualified personnel, but because of the around-the-clock nature of the hospital's activities, it has also necessitated many more workers, a larger payroll, higher costs, and inevitably higher charges.

As hospitals convert the results of medical research into ever more comprehensive patient care, they may reasonably expect that the percentage of the hospital budget allotted to payroll will rise to more than 70 percent. As wages rise generally, they must rise in hospitals. Hospital administrators in virtually every community face an acute and seemingly chronic shortage of personnel. Hospital careers offer well-recognized satisfactions of service, association with the aura of medical learning, and the prestige of the uniform of healing. But recruitment will not be easier until hospitals can compete with other employers' wages. Hospitals must make sure that they use their staff wisely and do not waste talent and training.

Automation can never be the complete answer for personal service institutions; reducing costs by increasing productivity is far more difficult in hospitals than in industry.

Yet I am optimistic enough to think that studies will show us how automation can be exploited more fully, for example, in food service, laundry, central supply, and other such departments. Through improved methods and work simplification, hospitals will undoubtedly be able to increase the efficient use of workers' time. We must stop viewing with alarm the rising costs of hospital care, but we must not cease our efforts to keep costs down to the minimum consistent with maximum quality. Hospitals must demonstrate to the public that they recognize the need for economical operation in line with sound business procedures.

Solutions to the problems created by rising costs and shortages of personnel as well as the radical changes in the patterns of patient care will be worked out through research by hospitals' administrative staffs, by all members of the health team, and by social scientists. We often think of research in terms of new drugs, new surgical techniques, and other giant steps in the march of medicine. There is other research that is conducted with as much sincerity of purpose and with results as directly related to patient care. After all, it is the hospital with its laboratories, clinics, and operating facilities that makes it possible for the physician to practice modern medicine.

Until lately research in hospital administration was sparse. We have finally been able to get underway, through foundation and Hill-Burton funds, the organized program of hospital research which we have desired for so long. The American Hospital Association has strenuously urged increased recognition of the importance of research. It was instrumental in setting up two important national research groups. One, the Commission on Hospital Care, offered the first analysis of the extent to which the Nation's health resources were meeting the increased demand for health services (8). The commission's report prescribed a much-needed pattern for orderly planning of health facilities, a pattern which influenced the development of the very successful Hill-Burton program.

The second, the Commission on Financing of Hospital Care, did the first comprehensive analysis of the basic problems in financing hospital care for the American people (9). The

American Hospital Association also participated in the Commission on Chronic Illness, which has completed a 7-year study of the problems of chronic disease, illness, and disability (10).

The Association led in the establishment of the Hospital Research and Educational Trust, a nonprofit, citizen-directed body to undertake needed research in hospital affairs. The trust has, from several sources, about \$4.3 million programed in current research or pledged for future research. It is conducting studies of medical records, hospital licensure, need for future hospital facilities, and construction and design.

I would certainly predict that in the years to come hospitals of all sizes and types will become more active in conducting research. For too long we have thought research could be undertaken only in large medical centers. Actually, all hospitals can keep the accurate records which offer a basis for investigations to determine such things as the relation of social factors to disease and a community's actual and potential needs for various health services. All hospitals can undertake studies designed to evaluate and improve their administration. If we stop labeling these activities with the bogeyword "research," perhaps we can encourage acceptance of the fact that they can be undertaken outside university citadels of learning.

You may have noticed that in speaking of these research programs and the extension of hospital services to which they lead—in describing to you the ways in which today's hospital is living up to its responsibilities as a community health center—my point of view has been rather one-sided; I have been dwelling on the functions of the community it serves.

Adequate preventive as well as curative health care has become an accepted part of the high standard of living which most Americans are now able to attain. The potential consumers of medical care have a right to help plan for community health, and they are becoming more vocal in their desire to do so. I believe that health care can be no better than the people demand. I believe that the people should be as concerned as professional health personnel with the form and the cost of medical care, and the method of paying for it. In the

United States we are fortunate that we have an interested and aroused public, which, if it does not understand all the technical details of our work, understands a great deal more than we frequently give it credit for; and recognizes the importance of health care.

Our community hospitals are built by voluntary contributions from private citizens. Some 115 million Americans are identified with hospitals even before they set foot in one, either through Blue Cross or one of the many commercial insurance plans. The hospital cannot refuse to respond to the demands which the public need places on it. The community in turn must support its hospital. Support it with money, yes, and with a supply of personnel; but above all with a vivid understanding of the hospital's purpose and encouragement of the professional hospital team.

Lay Leadership

In trying to assess the hospital in the rapidly changing community health picture, I find one constant of great importance, a constant unique to the United States. Our community hospitals are truly governed, not by a professionally trained group, but by laymen, community leaders, who are better known for other personal achievements, but who have demonstrated an abiding interest in the community's welfare. Of course, our hospitals are not unique in this regard. Professional educators do not generally govern universities; military men do not establish final policy in the Department of Defense; and nuclear physicists do not speak the last word in the Atomic Energy Commission's decisions on the uses of atomic energy—or space satellites. Major institutions other than hospitals are governed by boards of so-called "lay" trustees. Yet the most highly developed forms of contributed service in our society are those centered in our hospitals, with their trustees, their volunteers, and their members of the religious orders. The story of the founding of every voluntary hospital in America always has a basic theme, contributed service.

The hospital trustees of the Nation—some 50,000 of them—are entrusted with the responsibility of setting policy in medical institutions where only the most expertly trained physicians and paramedical workers can translate the latest

in scientific developments into the best of patient care. The point to remember is the desirability of this arrangement. The lay control of hospitals insures that the community's interest will never be overlooked.

Of course, hospital trustees and volunteers must be particularly sensitive to the hospital's purpose and needs. Theirs must be educated awareness, including a recognition of the need for good equipment and well-trained personnel, an understanding of the problems of the physician and his co-workers, and an effort to facilitate their dedicated labors. As professional health workers, we all have an obligation to educate our communities about the goals and means of health care.

The modern hospital has evolved, not step by orderly step, but by a series of rapid mutations which have not yet stopped. Advances in medicine and changing social and economic conditions are making new demands on the hospital. Its functions of caring for patients, educating future health workers, and serving as a medical research center reach outside its walls into the community. The American public is learning to demand more extensive health services. If the hospital is to maintain its place in the public esteem, it must be prepared to adapt to this demand.

Voluntary hospitals demonstrate how consumers of health services can be effective partners with the producers of these services. Such partnerships have obvious advantages and are bulwarks of strength to our free society. The degree to which the relationship succeeds in a hospital is a major factor in determining the quality of patient care, preventive medicine, and educational and research activities.

I believe that our voluntary hospital system, directed by lay leadership representative of the community, will continue to serve the people to the extent that the public desires service. In the voluntary hospital, the full partnership of an enlightened public, a learned and inspired medical profession, and a dedicated hospital administration represents an opportunity to offer the very best in health care. The American hospital was created out of the pattern of American democracy. It serves in a great tradition, and in the years ahead it will assume an even greater place as a community health center.

As an institution, it has done much and yet has much to do. It needn't be apologetic. It cannot be complacent. Its accomplishments and its challenges are succinctly stated in the Passavant motto: "More than yesterday. Less than tomorrow."

Water Pollution Control

Continued pollution of stream by municipality's sewage system after decree enjoining pollution constitutes civil contempt of court by municipality and criminal contempt by individual officials failing to take necessary steps to abate pollution, *In re Borough of West Wildwood et al.*, 42 N. J. Super. 282, 126 A. 2d 233 (1956).

The Borough of West Wildwood was directed by a chancery court in 1934 to comply with an order of the New Jersey State Department of Health to desist and refrain from allowing its improperly treated sewage to flow into Post Creek or to correct the inadequacy by a specific date. Four times over a period of 20 years the borough was found guilty of contempt of this order. The first contempt was punished by a fine of \$50 against each city councilman and \$250 against the borough.

The second finding of contempt was followed by the borough agreeing to make the necessary corrections in the sewage treatment plant. After the third finding of contempt, the borough was directed to raise the necessary monies to complete the correction of the sewage treatment plant.

Upon the failure of the borough to comply with this direction, the court in January 1955 levied a fine of \$5000 against the borough, in addition to a fine of \$25 per day until it com-

plied with the order and \$500 against each councilman-defendant who voted "no" or refrained from voting on the borough ordinance providing for correction and installation of new sanitary sewage disposal facilities and authorizing issuance of bonds to help finance such construction.

On application for remission of fines the court remitted the fine levied against the borough upon condition that it be used for the amortization of some portion of its bonded indebtedness. The fines levied against the mayor and councilmen, which were imposed for criminal contempt, were held to be beyond the power of the court to remit after the expiration of 60 days from the date of judgment.

For cases involving a similar situation see *Department of Health of State of New Jersey v. Borough of Fort Lee*, 108 N. J. Eq. 139, 154 A. 319 (1931), and *In re Borough of Fort Lee*, 108 N. J. Eq. 425, 155 A. 473 (1931).

Presently evident trends in death rates from leukemia offer no support for a theory that leukemogenic factors in the American environment have increased sharply within the last 15 years.

Trends of Mortality From Leukemia in the United States, 1921-55

ALEXANDER G. GILLIAM, M.D., and WILLIAM A. WALTER, M.D.

SOME of the deficiencies in the basic data available in the United States for studying the trend since 1921 of deaths attributed to leukemia have been cited by Sacks and Seeman (1). These limitations particularly involve the lack of comparability in the rubrics provided for leukemia in the several revisions of the International Lists of Causes of Death. Prior to the introduction of the fifth revision of these lists in this country in 1939, deaths charged to aleukemia were included with Hodgkin's disease. For this reason, in describing trends from 1921 to 1942, Sacks and Seeman only tabulated the "true leukemias." Cooke (2), however, has pointed out that in 1940 only 4.8 percent of all leukemia deaths were charged to aleukemia. These deaths yielded a crude aleukemia death rate of only 0.2 per 100,000, which should have little effect on trends whether included or not.

An additional difficulty with data for the United States, which is generally overlooked, is that all States were not included in the death registration area until 1933. In 1921 the registration States comprised only 58 percent of the land area of the country and less than 82 percent of the population. In 10 of the 14 States added to the death registration area since 1921,

the standardized leukemia mortality ratios in 1949-55 were lower than the average for the United States (A. G. Gilliam and W. A. Walter, unpublished data). The effect of this changing composition of the death registration States on the trends of leukemia mortality cannot be determined. Beginning in 1933, however, the data available and presented here refer to the entire United States, and beginning in 1939 include those deaths charged to aleukemia.

Sacks and Seeman, and Cooke, too, have pointed out that, while there has been a continuous increase in mortality from leukemia, the greatest increase has been in the older ages. In addition, Cooke has noted that in the age groups 0-4 and 0-14 the rate of increase was less between 1940 and 1949 than was observed in the previous 10 years.

To extend the observations of these authors, age-specific mortality rates for each race and sex were computed for each year 1921-55, for the registration States. The age-specific rates derived for white males and females are shown in figures 1 and 2. To achieve some degree of smoothing of annual variation, 5-year moving medians are plotted in figures 1 and 2 rather than the actual annual rates. Furthermore they are charted on a semilogarithmic scale so that changes in rate of increase may be visually evident.

With regard to the age-adjusted rates of leukemia mortality for both males and females of

Dr. Gilliam and Dr. Walter are epidemiologists with the Field Investigations and Demonstration Branch, National Cancer Institute, National Institutes of Health, Public Health Service.

NOTE. Rates for all ages adjusted to the age distribution of the population of the United States at the 1950 census. International List numbers included are 65a, 1921-29, 72a, 1930-35, 71a,b, 1939-48, and 204, 1949-55.

Figure 2. White males: trends of age-specific death rates for leukemia in the death registration States, 5-year moving medians, 1921-55.

NOTE: See note, figure 1

all ages, there would appear to be no change in rate of increase in the few years before and after 1933, the year in which all States were finally admitted to the death registration area. Beginning about 1940, however, there is a definite decline in the rate of increase, which would appear to be more pronounced among females than among males.

When trends for individual age groups are examined it is observed that there has been a substantial decline in leukemia death rates for both males and females under 1 year of age

since about 1940. In all other age classes, with the exception of those of 75 years or older, the rates have been increasing but the magnitude of increase has been declining. The decline in rate of increase, which is very evident in the younger ages, tends to be progressively less pronounced with advance in age. For those 75 years and older there is no discernible change in rate of increase.

In addition to this decline in rate of increase, there appears to be a tendency since 1950 for actual leveling off of rates in several age

groups. The leukemia experience of the next 5 years should be sufficient to demonstrate whether this represents a temporary slackening in increase in rates or a beginning reduction similar to that already observed among infants under 1 year of age.

A plot of the leukemia death rates for nonwhites has also been prepared, but because of the irregularities due to the small numbers of deaths involved, it is impractical to illustrate them. It may be said, however, that the increase among nonwhites has been materially

greater than among whites, with less evidence of a slackening in rate of increase. Such reduction in increase among nonwhites as is evident in annual rates occurred about 1948, instead of in 1940, and is less marked than among whites. In addition, the reduction in rate of increase is only apparent among males under 5 years of age and among females under 35 years.

As a further test of changes in leukemia mortality rates since 1921, average annual age-specific death rates have been computed for

seven 5-year periods during 1921-55, for each race and sex class. These are shown for whites in table 1 and for nonwhites in table 2. In addition, the annual percentage changes in rates from one time period to the next have been computed by the compound interest formula and are shown in the tables. The annual percentage changes in rates as given for whites in table 1 are in complete conformity with the trends of moving medians of annual rates which were shown in figures 1 and 2 and which have been described above.

For nonwhites, on the other hand, the annual percentage changes from one time period to the next, which are shown in table 2, are clearly too irregular to suggest any stabilization in rate of changes in rates for this race.

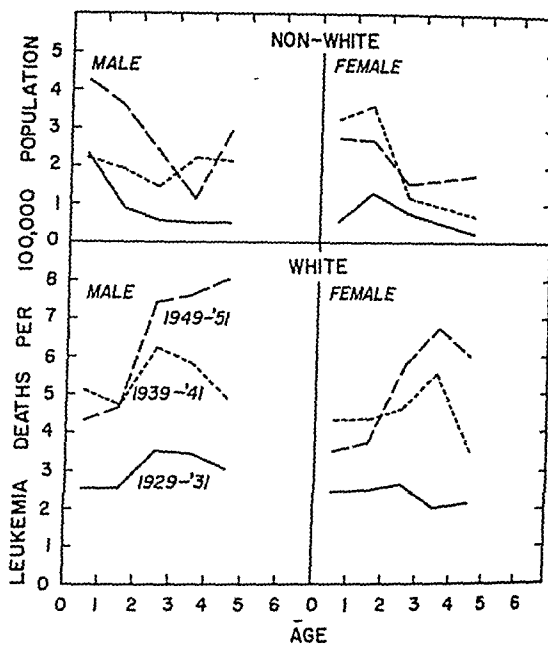

It may be added in passing that, among industrial policyholders of the Metropolitan Life Insurance Company, the total age-adjusted death rates from leukemia declined between 1951 and 1954, the last year for which rates were published (3). Whether or not this represents a temporary fluctuation, or a real decline in rates for this group, remains to be seen.

Persons Under 5 Years of Age

Hewitt (4) has extended the observation of Cooke (2) that leukemia tended to show a peak of occurrence in the third and fourth years of life. Walter and Gilliam (5) showed that this peak was present during 1949-51 for the white but not for the nonwhite population of the United States. In view of these observations, more detailed examination of mortality data for persons under 5 years of age appeared desirable. Accordingly, average annual death rates for single years under 5 were computed for 3-year periods centering around the censuses of 1930, 1940, and 1950. The results are shown in figure 3. Although the data for nonwhites are based on small numbers, there is in the three time periods a general tendency in this race for the rates to decline after the first year of life. Among white males, to the contrary, there is an opposite tendency which is present to some extent in all three time periods. Among white females, the latter general tendency is evident in the last two periods although not in the first.

Examination of mortality trends for the ages

Figure 3. Leukemia death rates for single years of age under 5 years for 1929-31, 1939-41, and 1949-51.

under 5 years during intercensal years is unprofitable because of the unavailability of reliable estimates of the populations at risk. Since 1940, however, the Bureau of the Census has published estimates (6) of the population for the ages under 1, 1 and 2, and 3 and 4 years. Leukemia death rates for each year, 1940 to 1955, inclusive, have been computed from these estimates, and the results for white males and females are plotted on a semilogarithmic scale in figure 4. For both sexes there is a regular decline in the rates for infants under 1 year old, which is offset in about the same degree by a rise in rates for children 3 and 4 years of age. Among females 1 and 2 years old the rates have remained at a fairly constant level, while in the males of these ages there is a tendency towards a decline in rates since about 1950.

Among the nonwhites the annual fluctuations arising from the small numbers of deaths make it impossible to form reliable conclusions about trends for these ages.

Lifetime Probability of Dying of Leukemia

Throughout the entire life span from birth onwards, the probability of dying of a disease

is a function not only of changing age-specific mortality due to that disease, but of changing survivorship from all other competing causes of death. As is well known, there have been marked fluctuations during the last 25 years, in the United States and elsewhere, with respect to expectation of life and causes of death in general. To estimate the combined effect of these general forces, together with annual changes in leukemia mortality, the lifetime probability of dying of leukemia has been computed for 6 years, distributed at 5-year intervals 1930 to 1955, inclusive, by a method from Spiegelman (7), which employs United States life tables and age-specific leukemia mortality for each year listed. The results of these computations are shown in table 3 for both races and for each sex. The percentage change in probability of dying of leukemia during each 5-year interval is also shown in the table.

In 1930 the betting odds were 185 chances in 100,000, or slightly less than 0.2 percent, that a white male would eventually die of leukemia. By 1955 this probability had risen to 684 chances in 100,000, or a little less than 0.7 percent. Changes of a similar kind, although of

different degree, are noted for white females and for nonwhites of each sex.

The percentage increase in probability of death from leukemia for each 5-year interval is shown in the lower half of table 3. The rate of increase is greater for nonwhites than for whites, but in all classes there is a distinct tendency toward a decline in rate of increase. Also, the changes in rate of increase, as estimated from lifetime probabilities, are less regular and are subject to greater fluctuation than when estimated from the annual probability of dying of leukemia, as shown in figures 1 and 2.

In view of the impossibility of determining from figure 4, with any degree of assurance, that the decline in death rates for infants under 1 year of age is entirely offset by the increase in rates for children 3 and 4 years of age, the probability of dying of leukemia during the first and second 5 years of life (birth to 5th birthday and 5th to 10th birthday) has been computed and is shown in table 4. The table shows that between 1950 and 1955 there has been a slight decline in accumulated risk of dying of leukemia in the first 5 years of life.

Figure 4. Trends of leukemia death rates for white males and white females under 1, 1 and 2, and 3 and 4 years of age, 1940-55.

¹ See footnote table 3.

Taken together with the trends of annual death rates for the ages under 1 year and 1 to 4 years (figs. 1 and 2), this strengthens the belief that this reduction may be real and not a fluctuation such as was observed in the other direction between 1945 and 1950. Regardless, however, of the certainty which might be placed in this conclusion, the table clearly shows that the risk of dying of leukemia in the first 5 years of life has at least been stabilized since 1940. During the second 5 years of life, on the other hand, there has been a perceptible, though slight, increase since 1940 in the probability of dying of leukemia.

Individual States

Unpublished tables are available from the National Office of Vital Statistics which give leukemia deaths, by age, for each State since 1935. Prior to 1942, however, deaths were assigned to the State in which death occurred rather than to the State of residence of the decedent. No information is available to determine whether or not the leukemia deaths recorded in some States prior to 1942 include any substantial proportion of nonresidents. With this reservation in mind, age- and race-adjusted death rates were computed by the indirect method for each State for three 3-year periods centering around the censuses of 1930, 1940, and 1950. The indirect method employed involved multiplication of the 1949-51 age-specific rates for the United States as a whole, for whites and for nonwhites separately, by the corresponding State populations as enumerated at the 1930, 1940, and 1950 cen-

suses. This procedure yielded the deaths expected in each State during each period, on the basis of the 1949-51 experience of the white and nonwhite populations of the entire United States. The observed deaths, divided by those expected on this basis, yield a ratio which, when multiplied by the crude rate for the United States for 1949-51 (58.18 per million), gives the State rate adjusted for age and race.

Table 5 shows the leukemia mortality rates for each State grouped in standard geographic regions. The percentage increases in rates between 1930 and 1940, and between 1940 and 1950, are also given. Rates for the entire United States increased 64 percent between 1930 and 1940 as compared with an increase of 43 percent between 1940 and 1950. This decline in rate of increase is evident in each geographic region except New England. In this area 3 of the 6 States showed increases in the rate of increase, but the number of deaths recorded for them forms a relatively small proportion of the total deaths credited to the entire region. All other regions show a decline in percentage increase, but 12 other States do not exhibit such decline. These include nearly half of the States in the East and West South Central regions, three in the South Atlantic, and half of those in the Mountain States. In general, these all represent States having relatively small populations or relatively low leukemia mortality rates, or both.

Since the basic data available do not give the race of decedents for many of the States during 1929 to 1931, comparisons cannot be made for changes in rate of increase for each race sepa-

rately, by State. For the entire United States, however, there was a much greater percentage increase for nonwhites during both periods, being 98 percent and 62 percent, respectively, for nonwhites as compared with 64 percent and 42 percent for whites.

MacMahon (8), who studied the increase in leukemia mortality among the white population of each State between two periods, 1938-42 and 1949-53, was impressed with the large percentage increase exhibited in five of the Mountain States—Nevada, Utah, Arizona, Idaho, and Montana. Three, and possibly four, of these States showed a greater percentage increase in leukemia deaths between 1940 and 1950 than was observed between 1930 and 1940. Inasmuch as the number of deaths on which the increases are based is small; since these States, except Utah, lack University Medical Centers, it is probable that some of their residents died outside the State, with the result that part of their increase in mortality from leukemia after 1940 is an artifact; and since 11 other States not in this region exhibited the same type of trend, we can see no reason to single these States out for particular consideration on the basis of these data.

Mortality Among Physicians

No published data are available in the United States for a fully adequate analysis of leukemia

mortality trends among physicians as a whole, or for any physician speciality group. With the exception of the report of Dublin and Spiegelman (9), all studies of leukemia mortality among physicians have depended upon leukemia deaths listed in the obituaries published in the *Journal of the American Medical Association*. Since these do not always give the cause of death, and since all physicians' deaths known to the association are not listed, it has not been possible to compute adequate mortality rates from these data. It has been feasible, nevertheless, to compute age-specific ratios of listed leukemia deaths to all deaths listed among physicians, and to compare them with ratios similarly derived for deaths recorded in the white male population as a whole. This has been accomplished, notably by Henshaw and Hawkins (10) and by Peller and Pick (11). Both studies yielded higher leukemia ratios among physicians than among the general white male population as a whole.

Ratios of this kind, even when computed on an age-specific basis, do suffer from some uncertainty as to how much of the result reflects an excess of leukemia and how much may be due to a deficit in other causes of death. At the present time, at least, such ratios would somewhat overestimate the rate of leukemia among physicians since Dickinson and Martin (12) have shown a deficit of 7 percent in mortality from all causes for this profession during the

years 1949 to 1951. Such ratios would also overestimate the rates of leukemia mortality among physicians if leukemia deaths were more regularly listed in the obituaries than were other causes of death.

Because of the interest in leukemia among physicians, it appears desirable to place on record their death rates and their trend. This is now possible through the courtesy of M. Spiegelman of the Metropolitan Life Insurance Company and Dr. F. G. Dickinson and L. W. Martin of the Bureau of Medical Economic Research of the American Medical Association, who have supplied us with unpublished data. These data are shown in detail in table 6 for the 5-year period centering around 1940 and in table 7 for the 3-year period centering around 1950. Spiegelman identified 102 leukemia deaths (table 6) among physicians between 1938 and 1942. This is 26 percent more than the 81 deaths which Henshaw and Hawkins (10) found listed in physicians' obituaries during the same period.

The tables also show rates for the same periods for white males in the United States as a whole, and ratios of the age-specific leukemia mortality rates for physicians to the rates for white males. These ratios decreased with age in 1940, but increased with age in 1950. In 1940 the age-adjusted rate was 75 percent greater for physicians than for white males as a whole, while in 1950 it was only 39

percent greater. This is due to the fact that the rates among physicians increased only 25 percent in 10 years, while those for all white males of the same ages increased 58 percent. Comparison of leukemia mortality rates in tables 6 and 7 also shows that there was a decrease in leukemia mortality in the 10-year period, for physicians under 55 years of age, which was more than offset by increases for those over 55.

Summary and Discussion

Mortality attributed to leukemia in the death registration States of the United States between 1921 and 1955 has been characterized by:

1. An increase in the age-adjusted death rate for all ages, in both races and in each sex, with the rate of increase greater for nonwhites than for whites.

2. A decline since about 1940 in the rate of increase among white persons, but little tendency toward a decline among nonwhites. For the entire population the percent increase dropped from 64 percent between 1930 and 1940 to 43 percent between 1940 and 1950.

3. A regular decline since 1940 in death rates for white infants under 1 year of age.

4. An increase since 1940 in death rates for white children 3 and 4 years of age, which tends to offset the decrease exhibited among infants. For all ages under 5 years, in both

rates and in each sex, however, the accumulated probability of dying from leukemia has been relatively stable since 1940, with an apparent tendency to decline among the whites since 1950.

5. A perceptible decline since 1940 in the rate of increase for all other age groups in the white race except for those 75 years of age and over. This tendency is more marked in the younger ages, and its magnitude decreases with age.

6. A smaller percentage increase between 1940 and 1950 than between 1930 and 1940, in two-thirds of the States.

7. A smaller increase between 1940 and 1950 among physicians than among white males of the same ages in the general population.

If these trends among whites persist, they will eventually result in stabilization or actual decline in the leukemia death rates for all ages. Without projection into the future, however, the trends presently evident provide no support whatsoever for a theory which postulates a sharp increase within the last 15 years in leukemogenic factors affecting the environment of Americans in general. On the contrary, the data suggest that such exposure has either become stabilized or has actually decreased during this period, if exposure to environmental factors is in fact responsible for the disease. The steady decrease in rate of increase in leukemia mortality in every age group among the white population under 75 years of age is entirely consistent with a theory of recent de-

crease in exposure of the general population to whatever causes operate to induce the disease.

Haldeman Named Division Chief

Dr. Jack C. Haldeman has been appointed chief of the Division of Hospital and Medical Facilities of the Public Health Service. He succeeds Dr. Vane M. Hoge, who has been named executive director of the newly created Hospital Planning Council of Metropolitan Chicago. Dr. Hoge is retiring after 30 years with the Service.

As chief of the division with the rank of Assistant Surgeon General, Dr. Haldeman will administer the Hill-Burton program which, as its executive officer from 1946 to 1948, he helped to organize. In 1948 he became the first director of the Service's Arctic Health Research Center in Anchorage, Alaska, a post which he held until 1951. Subsequently he served as chief of the Division of General Health Services, Bureau of State Services, and for the past year he has been deputy chief of the division that he now heads.

Health economists are concerned with the organization of the market for health services and the net yield of investment in people for health. The "optimum" use of resources for the care of the sick and the promotion of health defines the special field of inquiry.

Toward a Definition of Health Economics

SELMA J. MUSHKIN, Ph.D.

TWO RECENT developments, each traceable to scientific advances in medicine, have focused attention on health economics.

First, new therapeutic products have provided specifics for many infectious diseases that, less than 20 years ago, were important causes of death in the United States and other industrial nations. These changes in medical techniques, which have increased the physician's capacity to deal effectively with diseases, have altered patterns in the organization of health services. Concomitantly, problems associated with the costs of medical care have been intensified and have stimulated prepayment arrangements for meeting these costs.

These changes have also given rise to many questions about the nature of the "market" for health services; about the relation of plant "capacity" (hospital facilities, for example) to use of health services; and about variations in "demand" attributable to prepayment. Especially urgent are questions about shifts in "demand" due to third party payments for limited types of medical care and about effects of alternative methods of payment and compensation on the "price" of health services. These questions are illustrative of the many raised by altered patterns in the organization of health

services and altered methods of paying for health care. They comprise one set of economic issues.

A second set of issues arises from another development in medical science: the possibility of increasing life expectancy. Average life expectancy at birth in many of the nations of Asia and Africa—nations which include almost two-thirds of the world population—was until recently about 30 years. This may be contrasted with almost 70 years of life expectancy achieved in the United States. The potential increase in life expectancy sharply focuses problems of balance between population and resources, between work forces and output, in the industrially underdeveloped but densely populated nations of the world. Scientific advances in medicine and public health can be applied quickly and with minimum expenditures to reduce death and morbidity rates in these nations. Spraying with DDT, immunization with BCG, and treatment with penicillin have yielded dramatic results in reduced mortality from malaria, tuberculosis, syphilis, and yaws.

Reduced death rate has intensified a search for answers to specific economic questions so that the achievements in health will not be dissipated by the pressures of increased population on low food supplies, with the consequent intensification of poverty. Some of these questions are related to the means by which the net yield of investment in people for health may

Dr. Mushkin is an economist in the Division of Public Health Methods, Public Health Service, and research associate, Johns Hopkins University School of Hygiene and Public Health.

be measured, the relative amounts of complementary and supporting capital investment and capital growth required, and the effects of changes in health status on productivity. At the same time, the changing monetary value of man, in his productive capacities, effects an impact on economic growth.

These two sets of issues in common require, among other things, an analysis of the optimum use of resources for maintaining and improving the people's health and the quality of the population. Both sets of issues have been pressed by the requirements for policy formulation—public for health issues facing less developed nations, and largely private for health issues arising out of the medical market, at least within the United States.

Administrative Definition

What then is health economics? Generally, "health economics" has been used by health administrators to refer to any investigation that deals with money in its relationship to health. The two medical journals with economics in their titles perhaps give a clue to what those in the health professions consider to be encompassed within the scope of a health economics inquiry. One of these journals, *Medical Economics*, is essentially a business journal for physicians, and regularly features articles on physicians' office methods and finances. Special feature articles in 1957, for example, deal with the physicians' income, hours of practice, specialties, fee determination, voluntary health insurance developments as they bear on the physicians' practice and finances, cost of practice including malpractice insurance, taxation problems such as definitions of business expense, and problems of estate planning.

The second periodical, *Public Health Economics*, published by the Bureau of Public Health Economics of the University of Michigan's School of Public Health, abridges articles and news items. Materials abridged are classified currently in the following manner: legislation, governmental programs in operation (Federal and State), prepayment plans, health personnel, hospital and other health facilities, receipt of care, and developments in other countries. The first issues of this pe-

riodical in 1944 published news items on governmental health programs, views of the health professions on the organization and financing of health services, medical education, hospital organization and services, dental health needs and services, voluntary health insurance plans, and public health education. In the foreword to the first issues, Dr. Sinai stated, "... this publication is a tangible tribute to ... contributions toward the development of a new and vital blending of the medical and the social sciences. The blend is public health economics."

Thus "health economics" has been both broadly conceived to encompass the range of social sciences, including public administration, and narrowly conceived to deal with business methods of organization and of payment.

Economic Propositions

What has the professional economist had to say about health economics? Until fairly recently, economists have given little thought to the market organization of health services or to the net economic yield of investment in the health of people. This lack of attention to the medical market may be traced to the special characteristics of medicine that mark it as an exception to economic propositions that explain the mechanisms of the market generally.

There are several important characteristics of the medical market that differentiate it from the market of classical economics. First, the profit motive is not adequate as an explanation of the activity in the medical "market." Hospital care throughout the centuries has been either primarily public or under the auspices of nonprofit institutions. While services of physicians in the United States are organized on an individualistic basis as any profession or enterprise (and it is fair to say, even more so), physicians have accepted their social role in the community and have often cared for the sick and promoted health without remuneration for their time and skill. Also, professional motivation in pursuing the medically interesting case often causes the medical practitioner to evaluate his leisure, income, and work differently from, say, skilled operatives in industry.

Second, in medicine, price is not the sole

means by which demand and supply of medical and health services may be equated. As a social responsibility, private associations, nonprofit in form, and private practitioners have provided necessary services for those unable to pay. And fees for services have been graded in accord with rough evaluations of ability to pay. In the economy generally, however, the price system is the instrument for the allocation of goods among consumers and their competing demands. Government traditionally has been looked upon as an instrument to correct the market mechanism where it fails markedly to satisfy the wants of individuals. In the sphere of medical care, however, individual needs have been met historically, at least in part, by nonprofit organizations and by the practitioner guided by the code of Hippocrates.

Moreover, a competitive price has been generally absent from the medical market, at least until recently. In part, this is attributable to the absence of a homogeneous commodity. Skill and capacity vary with the individual abilities of health personnel, and needs of patients differ, too.

Third, medical services are personal services; money cannot veil the transaction. The cold impersonality of money, so much a part of all other "business" transactions, is largely absent from medical exchanges between those who give services and those who receive them. For a part of what one buys in medical services is a personal relationship.

Fourth, consumers do not choose between health services and other goods and services by means of a simple rational weighing of choices, for (taking consumer health expenditures as a guide) the consumer prefers to avoid, or remove the circumstances that compel, using resources for health purposes. In every income group there is a heavy concentration of expenditures for medical care among those families who suffer illness. This concentration suggests that consumer outlays are undertaken primarily to cure or provide services for the sick. This pattern of consumer preferences may be illustrated in other ways. For example, in any year, only about one-third of the population purchases dental services (1). About one-fifth of physician services are for preventive health services; the remaining serv-

ices are for the cure and diagnosis of disease (2). Moreover, data on expenditures and on the relation of expenditure to income suggest that the familial patterns of consumption are distorted when illness strikes.

Efficient organization of economic resources for health, guided by the consumer's preference, depends upon the consumer's knowledge and the extent of his education. Despite persistent efforts to educate consumers they reveal considerable absence of accurate knowledge about the quantity and quality of health services required. The nature of the medical service itself and its intangible character reinforce the consumer's lack of knowledge about his purchases, and impede a rational choice that could guide the allocation of resources.

Furthermore, in an individual's purchase of many medical services, there is a social utility. Purchase of health services for the prevention of contagious and infectious diseases, such as smallpox, poliomyelitis, and whooping cough, provides a utility, or a benefit, for the community as a whole. Even curative health services, such as those for the treatment of tuberculosis or syphilis, help to prevent the spread of the diseases; thus an individual's purchase of services for his own cure benefits his neighbor. These important "extra-buyer benefits," or "external economies" in the prevention of disease, are instances in which individual demand and market price underestimate the marginal and total benefits provided. Preventive health services would be undervalued, underpriced, and underproduced, unless administrative agencies (government or nonprofit) entered the market.

Population and Resources

While economists have devoted little attention to the medical market they have long dealt with population growth in relation to limited physical resources. Malthus' *Essay on the Principle of Population*, first published in 1798, triggered a series of economic postulates giving a man-against-nature view which earned economics its designation as the dismal science. Most important of these postulates for health programming was the iron law of wages.

Alfred Marshall, whose *Principles* (written in the decade 1881 to 1890) represents a transi-

be measured, the relative amounts of complementary and supporting capital investment and capital growth required, and the effects of changes in health status on productivity. At the same time, the changing monetary value of man, in his productive capacities, effects an impact on economic growth.

These two sets of issues in common require, among other things, an analysis of the optimum use of resources for maintaining and improving the people's health and the quality of the population. Both sets of issues have been pressed by the requirements for policy formulation—public for health issues facing less developed nations, and largely private for health issues arising out of the medical market, at least within the United States.

The blend is public health economics."

Thus "health economics" has been both broadly conceived to encompass the range of social sciences, including public administration, and narrowly conceived to deal with business methods of organization and of payment.

Economic Propositions

What has the professional economist had to say about health economics? Until fairly recently, economists have given little thought to the market organization of health services or to the net economic yield of investment in the health of people. This lack of attention to the medical market may be traced to the special characteristics of medicine that mark it as an exception to economic propositions that explain the mechanisms of the market generally.

There are several important characteristics of the medical market that differentiate it from the market of classical economics. First, the profit motive is not adequate as an explanation of the activity in the medical "market." Hospital care throughout the centuries has been either primarily public or under the auspices of nonprofit institutions. While services of physicians in the United States are organized on an individualistic basis as any profession or enterprise (and it is fair to say, even more so), physicians have accepted their social role in the community and have often cared for the sick and promoted health without remuneration for their time and skill. Also, professional motivation in pursuing the medically interesting case often causes the medical practitioner to evaluate his leisure, income, and work differently from, say, skilled operatives in industry.

Second, in medicine, price is not the sole

means by which demand and supply of medical and health services may be equated. As a social responsibility, private associations, nonprofit in form, and private practitioners have provided necessary services for those unable to pay. And fees for services have been graded in accord with rough evaluations of ability to pay. In the economy generally, however, the price system is the instrument for the allocation of goods among consumers and their competing demands. Government traditionally has been looked upon as an instrument to correct the market mechanism where it fails markedly to satisfy the wants of individuals. In the sphere of medical care, however, individual needs have been met historically, at least in part, by nonprofit organizations and by the practitioner guided by the code of Hippocrates.

Moreover, a competitive price has been generally absent from the medical market, at least until recently. In part, this is attributable to the absence of a homogeneous commodity. Skill and capacity vary with the individual abilities of health personnel, and needs of patients differ, too.

Third, medical services are personal services; money cannot veil the transaction. The cold impersonality of money, so much a part of all other "business" transactions, is largely absent from medical exchanges between those who give services and those who receive them. For a part of what one buys in medical services is a personal relationship.

Fourth, consumers do not choose between health services and other goods and services by means of a simple rational weighing of choices, for (taking consumer health expenditures as a guide) the consumer prefers to avoid, or remove the circumstances that compel, using resources for health purposes. In every income group there is a heavy concentration of expenditures for medical care among those families who suffer illness. This concentration suggests that consumer outlays are undertaken primarily to cure or provide services for the sick. This pattern of consumer preferences may be illustrated in other ways. For example, in any year, only about one-third of the population purchases dental services (1). About one-fifth of physician services are for preventive health services; the remaining serv-

ices are for the cure and diagnosis of disease (2). Moreover, data on expenditures and on the relation of expenditure to income suggest that the familial patterns of consumption are distorted when illness strikes.

Efficient organization of economic resources for health, guided by the consumer's preference, depends upon the consumer's knowledge and the extent of his education. Despite persistent efforts to educate consumers they reveal considerable absence of accurate knowledge about the quantity and quality of health services required. The nature of the medical service itself and its intangible character reinforce the consumer's lack of knowledge about his purchases, and impede a rational choice that could guide the allocation of resources.

Furthermore, in an individual's purchase of many medical services, there is a social utility. Purchase of health services for the prevention of contagious and infectious diseases, such as smallpox, poliomyelitis, and whooping cough, provides a utility, or a benefit, for the community as a whole. Even curative health services, such as those for the treatment of tuberculosis or syphilis, help to prevent the spread of the diseases; thus an individual's purchase of services for his own cure benefits his neighbor. These important "extra-buyer benefits," or "external economies" in the prevention of disease, are instances in which individual demand and market price underestimate the marginal and total benefits provided. Preventive health services would be undervalued, underpriced, and underproduced, unless administrative agencies (government or nonprofit) entered the market.

Population and Resources

While economists have devoted little attention to the medical market they have long dealt with population growth in relation to limited physical resources. Malthus' *Essay on the Principle of Population*, first published in 1798, triggered a series of economic postulates giving a man-against-nature view which earned economics its designation as the dismal science. Most important of these postulates for health programming was the iron law of wages.

Alfred Marshall, whose *Principles* (written in the decade 1881 to 1890) represents a transi-

tion from classical to modern economics, wrote: ". . . earlier economists argued as though man's character and efficiency were to be regarded as a fixed quantity. . . . [Economics] is getting to pay every year a greater attention to the pliability of human nature, and to the way in which the character of man affects and is affected by the prevalent methods of the production, distribution and consumption of wealth" (3a).

Marshall, dealing with the agents of production in book 4 of his *Principles*, considers not only the growth of the population but the health and strength of the population. Marshall opened a chapter of this book with, "We have next to consider the conditions on which depend health and strength, physical, mental and moral. They are the basis of industrial efficiency, on which the production of material wealth depends; while conversely the chief importance of material wealth lies in the fact that, when wisely used, it increases the health and strength, physical, mental and moral of the human race" (3b).

While some few economists have recognized the concept of "personal capital," of personal hazards to workers in industry as "social costs," and of health (physical and mental) as a component of workers' efficiency, by and large these concepts have been qualifications rather than integral parts of their economic propositions.

Three interrelated facets of analysis are essentially involved. Population pressures on resources, constituting one facet, have been dealt with in economic discussions of underdeveloped areas of the world (4). The Malthusian theory has gained new importance in this context.

The second facet is the capital value of man. Dublin and Lotka, demographers and actuaries rather than economists, have contributed the major work on the methodology of evaluating the capital represented by man (5). For their purpose they define capital value as the present and discounted value of future earning power of the wage earner, reduced by the costs of birth, upbringing, and maintenance during a working life. In their study they traced the thinking on man's capital value through the works of Sir William Petty, Adam Smith, William Farr, Frederick Engel, Alfred

Marshall, Irving Fisher, and others. Subsequent studies of special importance to this particular analysis are those made by Wolfbein and Wool for the U. S. Department of Labor on the measurement of a working life (6, 7).

The third facet is the application of cost-benefit ratios to health programs. Work in this area has been traced to the 16th century study of Jean Bodin, to Richard Cantillon's essay on *The Nature of Commerce in General* published in 1755, and to Quetelet, a social statistician, who wrote in 1835: "In his early years, man lives at the expense of society; he contracts a debt which he must one day discharge; and if he dies before he has succeeded in doing so, his life will have been a burden rather than a benefit to his fellow citizens . . ." (8). Economic studies of cost-benefit ratios of health programs have been carried out largely by health administrators and others in the health professions rather than by economists. Hermann M. Biggs expressed the health administrator's concern in his slogan coined more than three and a half decades ago for the New York City Health Department: "Public health is purchasable; within natural limitations a community can determine its own death rate."

Winslow-Myrdal Exchange

Health cost-benefit analysis has gained new significance since World War II, especially in the studies and activities of international organizations. Major contributions to this analysis were made by C.-E. A. Winslow in his 1951 volume on *The Cost of Sickness and the Price of Health*, by the exchange of views between Winslow and Gunnar Myrdal before the Fifth World Health Assembly of the World Health Organization in 1952, and in the subsequent volume by Myrdal on *Economic Theory and Underdeveloped Regions* published in 1957.

Differences between Winslow's views and those of Myrdal are largely differences in emphasis. Winslow argued that investment in health promised large dividends in life capital. For in the less-developed areas of the world where there was no surplus to invest in the profitable enterprise of health, the vicious cycle

of poverty and disease pursued its course unchecked. "Men and women were sick because they were poor; they became poorer because they were sick, and sicker because they were poorer" (9a). The doctrine that successful health programs will increase the sum of human misery, Winslow said, is founded on the fallacious assumption that there is some basic law limiting economic development to that which has at the moment been realized. He pointed to improvements in agricultural production in the less developed areas of the world, to the development of mineral resources, to other social as well as economic measures improving the well-being of the population, and to the supplementation of these measures by efforts in some countries to limit excessive rates of population increases. He emphasized that the public health programs cannot be planned in a vacuum, but only as a vital part of a broader program of social improvement (9b, 10). He urged health leaders to "keep careful records of the cost of their health programmes and of the actual results attained, and make estimates of the economic gains corresponding to the decreases recorded in mortality and morbidity" (11).

Myrdal, starting from Winslow's thesis of a "vicious cycle," elaborates a theory of circular causation. In brief the Myrdal theory is that at one point of time there is accommodation in society between opposing forces. If either of two opposing forces changes, Myrdal writes, a change is bound to occur in the other force, "and start a cumulative process of mutual interaction in which the change in one factor would continuously be supported by the reaction of the other factor and so on in a circular way. . . . The point is not simply that many forces are working in the same direction. They are, in fact, not doing so. In general there are periods when opposing forces balance one another so that the system remains in rest until a push or a pull is applied at one point or another. When the whole system starts moving after such a shock the changes in the forces work in the same direction, which is something different. And this is so because the variables are so interlocked in circular causation that a change in any one induces the others to change in such a way that these secondary changes support the first change, with similar tertiary effects upon the

variable first affected, and so on" (12). Myrdal notes that if his theory of cumulative causation is valid, an upward movement of the entire system could be caused by pressures applied to one or several points in the system. However, in agreement with Winslow, he argues that rational policy should not induce a change in only one factor, especially with sudden or great force.

Drawing on his theory of cumulative causation, Myrdal argues that it is far from a simple matter to define or to measure the economic value of programs directed to the promotion of a population's health.

Costs and benefits are likely to be different in the short run from what they would be otherwise and to be different in different environments. Long-run values depend on the interrelationship of factors in any given society.

Myrdal emphasized that the success of health programs will depend entirely on whether they are appropriately integrated in a program of general economic development. He thus agreed with Winslow that health programs should "be a vital part of a broader program of social reconstruction."

Myrdal also agreed with Winslow that a health program could increase the number of persons in the productive age groups and their productivity. But, he emphasized, "the economic value of preventing premature death . . . depends entirely upon whether such an economic development is under way which ensures productive work for the greater number of people we thus keep alive" (13). If death rates are reduced in areas in which there is already substantial unemployment, poverty could be aggravated. While Myrdal, in common with Winslow, questioned the static notion of a "population optimum," in view of the expandability of production resources, he laid far greater emphasis than Winslow on the need for capital investment in production facilities. The amount of planned capacity required to prevent economic stagnation and increased distress would be enlarged by a truly successful health program.

Myrdal suggested that calculations on the price of health and the cost of illness should be based on something other than a dollar value of people.

Success of a program, for example, might be calculated on savings in life and abilities rather than dollars. Costs of alternative programs, or of their administration alone, might also be compared without reference to the dollar value of people.

The Winslow-Myrdal exchange has served to point up three needs: (a) greater precision in defining measurements of the cost of sickness, (b) more careful distribution between primary and secondary impacts and effects of health programs, and (c) a more careful formulation of assumptions that underlie alternative economic models (static or dynamic) used in estimating the costs of sickness. The exchange, moreover, has served to provide a broad perspective from which to explore the subject matter of health economics.

Health Economics Defined

Tentatively defined, health economics is a field of inquiry whose subject matter is the optimum use of resources for the care of the sick and the promotion of health. Its task is to appraise the efficiency of the organization of health services, and to suggest ways of improving this organization.

Promotion of health patently involves more than services of the health professions. It includes food, housing, recreation, and clothing, but, although they contribute importantly to health and wellness, they must be excluded from the scope of health economic studies. Unless they are excluded, the scope of these studies would encompass all economic activities and the special problems of health economics would receive inadequate treatment. While the scope of health economics may be delimited in this way, account must be taken of the competing uses of scarce resources, the impact of economic levels and economic growth on the status of health, and the need for health services.

The allocation of economic resources is generally determined in the market by the preference of consumers for different types of consumer goods and by the preference of workers for different types of work, leisure, and income. Welfare economists have taken these preferences, as expressed in the market, as the guide to optimum use of resources (14-16).

But there are a number of reasons why these preferences are not a wholly reliable guide to optimum use of health resources, even when the word optimum is used in this special sense.

First, the consumer would prefer to avoid illness and the purchase of health services. And, as has already been indicated, there are sizable "extra-buyer benefits" in an individual's purchase of medical services. Others in the community benefit from his purchase. Purchases by some consumers, for example, of influenza vaccination during the recent epidemic prevented further spread of the disease. The value of the medical services to each consumer did not depend upon his consumption of medical services alone but upon decisions of his neighbors as well. Those who made no purchases of influenza vaccine also benefited. Thus, the social value of medical services is far larger than the private marginal value. Individual decisions of a consumer are therefore inadequate as an efficient guide to the optimum allocation of resources for health purposes. For these individual decisions undervalue health services, which results in an underproduction of these services.

Second, some health services do not lend themselves to pricing on the market so that society's preference for them cannot be adequately valued on the market. Air and water pollution control measures, fluoridation of water supplies, and mosquito control are examples of these services. Furthermore, the price system for individual services is not applied in all cases: (a) the medically indigent are not excluded from care when they are sick, and (b) public safety and health sometimes require direct provision of health services and the removal of the individual from the community. Public hospital services for the mentally ill and for those with tuberculosis are illustrative of services placed outside the price-market system.

Third, the allocation of health resources is determined by a mixture of private market decisions and administrative decisions. "Administrative decisions" include those decisions made by the government, private nonprofit agencies, and professional organizations. Decisions concerning some health facilities (the building and size of a general hospital, for example) are

made by voluntary agencies. The Visiting Nurse Association determines the availability of part-time nursing care in many communities. In some places the content and quality of rural health services are determined by the regional organizations associated with medical schools. The principles underlying these administrative decisions and the way in which they influence the allocation of health resources need to be explored.

It may be that the principles underlying public budget decisions are applicable to administrative decisions of voluntary health agencies as well as public agencies. While economists have largely neglected theories of public expenditure in favor of theories of taxation and policy, analysis of governmental budgeting has begun. The Joint Economic Committee of Congress, by its 1957 study of Federal expenditure policy for economic growth and stability, has stimulated the development of principles for determining public budget (17, 18). Review of the work is needed to assess its contribution to our understanding of the optimum allocation of economic resources for health.

Consumer preferences as expressed in the market are one guide to optimum use, even though an incomplete guide. Another thing to look at is the effect of health programs on labor resources and production. Gains in output as a consequence of health services may equal or exceed (in a given period of time) the resources used for health. The number and quality of new manpower resources must be compared with the health manpower used in the provision of services. For example, it would be possible to compare the amount of manpower used in providing health services in the United States with gains in labor force participation resulting from reduced death rates. Reduced death rates in the United States have resulted in a decline in separations from the labor force at all ages up to age 65. Despite the marked delay in entry into the labor force by young people, and the earlier exit from the labor force by those in the older age groups, the male worker today puts in many more years of work than did his counterpart 50 years ago (19). The problems of cost-benefit measurement have been mentioned in the discussion of the Winslow-Myrdal exchange. The concepts and

methods of measurement require extensive further study. Not potential but actual increases in production under prevailing conditions of employment must be measured against the cost of health services in order to determine their relationship to the economic optimum.

One additional aspect of the problem may be mentioned. The economic optimum bears some relation to the amount of health resources required to provide care for all the illnesses in the population. The optimum may be below or above the amount of health services suggested by professional standards. Standards of health resource requirements are familiar to the health practitioners. Professional planning for health services and setting standards are characteristics of the health field. Standards of professional education, requirements for entrance into the health professions, hospital standards, and even in some instances standards of care are determined by professional groups. Moreover, government, by compulsory measures, has enforced standards of public health. For example, vaccination is required as a condition for admission to school, and standards are set for the distribution of milk, for food handlers, and for water supplies.

The National Health Survey is designed to provide data on sickness in the population. In discussing the potential uses of data from such a survey the U. S. National Committee on Vital and Health Statistics indicated that quantitative information would provide a basis for sound evaluations of health facilities, personnel, and programs as well as for a determination of how available resources should be divided among programs (20). In an earlier study, Lee and Jones related sickness in the population to the needed volume of health services and manpower requirements (21).

The subject matter of health economics includes factors that determine price patterns for health services, ways in which the materials, goods, health manpower, and facilities are brought together at the right time and place and in the right proportions to provide health services, and ways in which the different health goods and services are coordinated. The mechanisms by which goods and services are coordinated are "trade" in the market by the consumer's purchases of health goods and services,

professional codes of performance, and governmental and voluntary agency planning and budget decisions.

Health economics also includes in its subject matter the effects of health services on the size, character, and efficiency of the work force and population. It seeks to gain an understanding of the interaction of levels of living, production, and physical and mental wellness. The health factors which make for work absence, for retirement from work, for labor turnover, for the quality of performance on the job, and for job satisfaction fall within the scope and concern of health economics. The general topics which need to be considered in a comprehensive treatment of the economics of health include the interaction of health services and gross national output, population growth and economic development, and productivity of labor forces; health problems associated with industrial development; the supply of health services; utilization of services and their pricing; and financing of public and nonprofit agency programs.

The scope of inquiry included in the tentative definition of health economics is by no means novel. It is suggested by the work that is going forward in the bureau of medical economics of the American Medical Association, and the bureau of economic research and statistics of the American Dental Association. These organizations have explored the interaction of use and price of health services, health manpower, and facilities and consumer demand. The studies of Eli Ginzberg, Herbert Klarman, and others have increased our understanding of the economics of the hospital system (22). Ginzberg's work has also included an examination of the special economic problems of health manpower and methods of providing care (23, 24). And an increasing number of doctoral dissertations in economics have been concerned with these, or similar problems.

Summary

The health administrator has usually equated "health economics" with "money questions in the field of health." But, money is not the central problem of health economics. Health economics is concerned with the optimum use of scarce economic resources for the care of the

sick and the promotion of health, taking into account competing uses of these resources. The basic problems are of two kinds: the organization of the medical market, and the net yield of investment in people for health.

Consumer preferences are not an adequate guide to the optimum allocation of resources for health. There are a number of reasons why this is so. For one thing, a consumer would prefer to avoid the illnesses which require use of resources for health purposes. For another, his neighbors benefit from the medical services he purchases, for example, "flu shots" during the recent influenza epidemic. Individual decisions undervalue health services, and would result in underproduction of these services unless supplemented by actions of private voluntary agencies and government.

Report of International Association of Gerontology

A conference of the European section of the Social Science Research Committee, International Association of Gerontology, held in Copenhagen, Denmark, in October 1956, discussed pensions, assistance, and levels of living, work and retirement, and family and institutional care. The conference recommended that, for purposes of comparison, data be collected in various countries on old people living alone or with relatives, those living in institutions and nonprivate households such as hotels, those who have surviving children, and those who are bedridden, housebound, or limited in movement.

Speakers from the United Kingdom, Italy, Denmark, and the Netherlands described and discussed surveys of income, budgets, living conditions, family relationships, pensions and retirement, research on employment, causes of institutionalization, costs of institutional versus home care, and sociomedical surveys.

The proceedings, entitled "The Need for Cross-National Surveys of Old Age," are available from the Division of Gerontology, University of Michigan, 1510 Rackham Building, Ann Arbor, Mich.

professional codes of performance, and governmental and voluntary agency planning and budget decisions.

Health economics also includes in its subject matter the effects of health services on the size, character, and efficiency of the work force and population. CONFERENCE REPORT

URBAN GROWTH

- POLICY
- PLAN
- PROCESS

ON MARCH 18-20, 1958, the National Health Forum of the National Health Council, sponsored by 63 member associations, was held in Philadelphia in conjunction with the 10th annual meeting of the National Advisory Committee on Local Health Departments.

The meetings dealt primarily with stresses produced by increasing urbanization; the financial and organizational implications of metropolitan growth; the effects and predictable eventualities facing local health departments, the dental and nursing professions, and hospitals; and the need to revise obsolete or anachronistic jurisdictions.

Comments of 15 of the 60 speakers at the forum follow. Their full identification appears on page 796.

Major Threads

In his summary, Wolman said the forum "took up the plight of 100 million in a world not made for them." He commiserated with those speakers who were distressed "by the existence of emotions, feelings, and action contrary to the prevailing mode of professional thought." And he offered philosophical solace as he described three major threads in the fabric of the discussion.

Signs

and

With this issue, a new department, Signs and Symptoms, is opened. Its main purpose is to provide a setting for what Dr. Joseph W. Mountin once called gems of public health practice. In addition to rare gems, it will give brief notice to other events or activities presumably of interest to readers. The doings of local and State health organizations will be the prime, but not the exclusive, focus of this department, especially if they indicate an important trend or some outstanding development or achievement. Contributions are welcomed.

Directory of Services

A directory describing all services in Greater Cleveland, Ohio, for care of the chronically ill has been published recently by the Cleveland Academy of Medicine and the Welfare Federation of Cleveland.

Intended as a reference for doctors and staff members of health and welfare agencies, the 118-page book lists about 200 different agencies.

In addition to medical facilities, the services described include nursing and rehabilitative, educational, financial, and casework assistance. Special sections deal with the treatment of chronically ill children, older persons, and veterans.

Information about each agency includes: services, eligibility requirements, area served, fees, hours, and referral procedures.

The directory has been distributed to some 2,800 doctors in the Cleveland area.

Traveling Clinic

Rural arthritic victims in Westchester County, N. Y., are being treated in their homes by therapists. The New York State Chapter of the Arthritis and Rheumatism Foundation sends therapists to patients unable to leave their homes or unable to travel to distant clinics.

The patients' private physicians approved the program and consulta-

tion with them has resulted in the training of visiting nurses in rehabilitation and the enlistment of help from social workers, nutritionists, and others.

By the beginning of June 1958, nearly 100 patients had been visited and 38 cases had been closed.

Pay for Patients

In a pilot program 25 mental patients have been working for pay at the New York State hospital in Central Islip.

Patients work at small handicrafts or such simple tasks as sewing buttons on cards.

Dr. Francis J. O'Neill, director of the hospital, reports that the patients are not approaching financial independence, but he feels the work advances rehabilitation.

Keeping Current

Responsibility for keeping current with public health literature is managed by the Saanich and South Vancouver Island Health Unit, Victoria, British Columbia, by giving each staff member an opportunity to report at a regular meeting on reading he has done.

H. George Henderson-Watts, senior sanitary inspector, reports that staff members give the title, author, and source; a brief statement of the author's purpose; a comment on

the noteworthy aspects of the paper; and the conclusions of the author and reviewer, if any. The paper itself is not read to the staff as a rule; the purpose of the review is simply to inform the staff and to encourage reading in pertinent fields. Reviews ordinarily are limited to 5-10 minutes. Time is also allowed for questions and discussions.

Periodicals, bulletins, and magazines are assigned on a 6-month or yearly basis.

Staff members are encouraged to read in detail the papers they review, to mark important points, and to read them a second time before offering their review.

Home Safety

The final report of the California Home Safety Project covering the years 1953-57 has been issued by the California Department of Public Health. The 165-page report reviews the home accident problem in California and outlines a program of State and local health department activities. It emphasizes the epidemiological approach to accident prevention. Distribution of the report is limited.

Hearing Tests

Audiometric tests for parents help them to understand corrective therapy and sound range limitations of children with hearing losses, the Alaska Department of Health reports.

The tests, offered during National Hearing Month in May 1958, were available to 5 communities; 196 adults were tested.

Glaucoma

In the summer of 1957 funds from the Public Health Service enabled the District of Columbia to begin examining residents over age 40 for glaucoma provided they were not under care of an eye doctor. By the end of May 1958, 3,806 patients had been examined and 27 cases of glaucoma verified. An additional 233 patients were under observation.

in the core city, a challenge to health agencies to make greater use of thruways and telephones, which he said are too little appreciated as great public health contributions.

- Research in planning, which he said "too often takes a turn in seeking how to curb those who persist in misunderstanding us."

He did not attempt to review all the major aspects of urban growth, but stressed Luther Gulick's admonition to recognize that the metropolitan area exists, to stop describing it and accept it as a form of behavior or misbehavior, and to revive the concept of community, with its implications for both individuals and the mass.

In conclusion, he said the fiscal basis for the urban complex needs much further consideration. He ended with, "Let us try to facilitate the transition and minimize the hurt."

Demographic Considerations

Speakers generally grasped the concept that growth of cities and populations poses a challenge of management or limitation. As a matter of policy, Isaacs declared that preoccupation with the welfare of random individuals and families was distracting attention from the common good. To illustrate public inconsistency, he observed that while health services reduce death rates, contributing to net population growth, the powers of the gods to destroy whole populations rest in the hands of a few, with the avowed objective of securing the redemption or well-being of every individual.

He predicted that "rigid governmental, economic, and social controls beyond any that we have known will be required" to protect the community interest, and that major mental stresses would result from "the reversal of almost unlimited freedom of action to strong community controls." While he conceded that regional confederation or cooperation might manage most metropolitan needs of the present, he said that in reality we have not been able to establish such instruments of government for more than a fraction of our population, and he asked, "Will we be able to solve the problems of 230 million in 20 years, or 330 million in 50 years?"

Price and others observed that the popula-

tion was not only growing but moving in a pattern which outmoded established structures of government.

Descriptions of this movement were offered by Cook, Moore, and Gulick. The world's population, Cook observed, is increasing by 45 million a year, 125,000 a day. The world over, too, there is a relentless movement of rural populations to urban communities. Once there, the people do not remain static. In the United States in recent years, more than 30 million people have moved each year at least from one house to another; 10 million moved to a different county.

Moore observed that there are now 174 metropolitan areas in the Nation, and by 1970 there will probably be 10 or 20 others. These areas contain almost 100 million people at present; by 1975 it is estimated that two-thirds of the American population will reside in such areas. Thirty percent of the Nation's inhabitants now reside in the 14 metropolitan areas having more than 1 million people.

Gulick pointed out that there is now a 600-mile linear city of 29 million people on the east coast. From San Francisco south, on the west coast, there is a similar development.

Characteristic of this development, Gulick said, "is a fluidity of population and economic life. This flow changes the basic structure of family, community, social relations, employment choices, shopping, education, communication, and political associations. The new metropolitanism profoundly disturbs most of our social institutions such as churches, clubs, societies, voluntary hospitals and charities, cultural and recreational establishments, political parties, and governmental operations."

The new metropolitan community is different from what we have known generally in the past. "It is a split-level creature," Gulick commented, "with personal human relations at one level, and broad, impersonal community consciousness at the other. And most people live in both levels."

Effect on Health Services

In the face of such growth, Haldeman observed that within the past 5 years there has been little progress in revising or extending

some areas, and growing thinner each year as the population most in need of health services (the very young and very old) increases.

Staffing and financing of local health services are considerably more difficult in health departments serving populations of under 100,000 than in large cities.

In such places, either additional staff and funds, or a major realignment of duties of personnel presently employed, or a change in the basic role of the health department is needed, he said. "Which—or which combination—shall it be?" he asked. "What more functional areas can be defined as a suitable geographic base for health services?"

Jurisdictional Autonomy

Several speakers observed that the main difficulty in pursuing a governmental solution to the intensified needs of metropolitan residents is to see that federation does not in any way infringe upon the identities of existing local units. Stepping up State action, Bromage suggested, is the quickest means of making metropolitan government possible. "Metropolitan councils arising out of interstate compact and crossing State boundaries," he said, "are not beyond the realm of possibility."

One means of effective compromise was suggested by Moore: a metropolitan council that would be assigned only metropolitan matters. The local units would be responsible for their normal, nonmetropolitan activities, as in the Toronto plan.

"The first step towards determining the form of government required to meet our needs," Moore said, "is to define the kind of urban community we want." The decision on this matter, he feels, is primarily a local one. It must be appraised on the basis of the probable effects of the dispersal of industry, automation, nuclear energy, wider distribution of natural gas and oil, Federal highways, changes in marketing and distributing, standards of living, and longevity. "There is no need," he cautioned, "to seek uniformity in the forms and patterns of government in all great urban areas: diversity is still desirable."

Past attempts to solve metropolitan problems, Moore argued, have usually been directed

not against the total need but to some fragment of special interest. Such efforts have generally failed to produce important results. Piecemeal attacks, moreover, have frequently resulted in the creation of public authorities and special districts. If pursued generally, he said, "this could be the route to destruction of local government and popular control as we know it."

Dibeler considered decentralization of health agency operations through the development of volunteer neighborhood organizations a means of providing solutions for some of the health problems created by urban sprawl.

The newly burgeoning communities, Dibeler pointed out, lack solidarity and suffer from absentee leadership, since many of the residents are employed in nearby cities, making it difficult for anyone to organize them into a health-conscious community.

The city health officer is in no less of a predicament. Neighborhoods catering to one class of people, structured according to a relatively stable age-sex pattern, explode and disappear. In their place is another group of people. "The problems of providing health services and health education here," Dibeler said, "are increased by the introduction of new groups whose culture is not well understood and among whom there is often little identifiable leadership. Problems of communication are increased by language barriers and varying culture."

Local Solutions

In combating the effects produced by outmoded institutions several governments, on different levels, have initiated or contemplated means of developing new methods and new institutions.

In New Haven, Conn., a regional planning organization was formed in 1948 to bring the surrounding communities closer together in function and direction. Andrews referred to the redevelopment project of the Yale University School of Medicine and its department of public health as one outcome of regional planning. Located in the first area selected for clearance and rehabilitation, the project covers 150 acres of land. Additional projects, now in

traditional local health services. One-fourth of the counties in the United States, with nearly 10 percent of the population, are still without organized local health services. Therefore, he put these questions:

Is the local health department an effective instrument for some areas but not others?

Are there circumstances so unique in the areas still without a local health department that some entirely different mechanism for the delivery of public health services will be required? If so, what should it be?

Are other community resources already pro-

viding, in an acceptable manner, the service ordinarily supplied or arranged for by the health department?

What kind of studies should be undertaken to supply the missing links in our information?

Concern with patterns of health services for the near future is not confined to counties presently without local health departments, he added. Many, many more have only fragmentary service that in no sense meets the health needs of today.

Because of limitations in staff and financial resources, the coverage of service is thin in

Canons of Aesthetics

Some noted American planners and architects appear to me to be on the wrong track. They are so enamored of old cities that they even like "quaint" slums and can see nothing but ugliness in any modern city. So hostile to any apartment are they that they criticize any high-rise multiple dwelling; and so in love with the open land that they want nothing but cottages scattered through the countryside. All such canons of aesthetic value and beauty have the total weakness of ignoring not only relativity and the influence of the total environment, but of flying in the face of human need, denying satisfying classical illustrations, and failing to give any sanction to functional beauty.

The British *Architectural Review* group starts quite differently with the "stratified environment," that is, with relativity, and seeks the canons of beauty first by finding for each defined major type, or stratum, of land settlement its appropriate style of development and the appurtenances which will give it "unity." As they say in the December 1956 issue, "There is a 'town' way and a 'country' way and a 'wild' way of doing everything, and to confuse them is to ruin any hope of integrity from the beginning." It is this unity and integrity, type for type, which they find aesthetically right.

On the basis of British land uses and needs, they then classify all of England into five divisions, or types, for practical purposes: wild, country, arcadia,

town, and metropolis; with two added special divisions, rural industry and major roadways.

For each of these types of land use these British architects and planners then seek the appropriate "way" and design, "cutting out useless verticals." The third step is to fit everything together with the minimum waste of space, a principle of economy for each type. Then finally, they say, "the residue must be camouflaged, and made one with the surrounding landscape."

With this approach, one can see why the same high building or solidly paved square will be beautiful in a city, but ugly in a rural setting; why even advertising signs may not be offensive in a business district; why large "natural" open spaces are no addition to a city center; and why a Cotswold cottage may be beautiful in the country, but absurd as a comfort station in a city park.

On the aesthetic side, it seems to me, the British, and a few American architects, like Neutra and Walker, have found the answer to the question. "What's so 'bad' about urban sprawl?" The thing that is "bad," is that in the "sprawl" regions we are mixing several incompatible types of land development, thus finding ourselves, without confinement, in a series of conflicting and unreconcilable categories each of which should be subject to its own appropriate canons of beauty.

—LUTHER GULICK, president, *Institute of Public Administration*, in an address to the *American Association for the Advancement of Science*, December 27, 1957.

Family care programs, community mental health services, and stream pollution control are matters for cooperation among neighboring municipalities and for action at the county level of government. On the interstate level, water and air pollution problems may be solved. At the present time, New York, Connecticut, and New Jersey have an Interstate Sanitation Commission for the control of water pollution affecting those States. On the Federal level of government, or Federal-State level, are such matters as hospital construction and the control of epidemics. The recent efforts in the Asian influenza epidemic and the Hill-Burton Act are evidence for this kind of cooperation.

"There are relatively few eventualities that do not engage the attention of more than one isolated agency," the Governor said. As an example, he showed how six State departments participated in the establishment of a program for New Jersey's senior citizens. The agencies concerned were: the New Jersey Department of Health (chronic illness and needs of the aging); Department of Institutions and Agencies (public assistance, institutional care, and hospital and nursing home supervision); Department of Labor (employment service and rehabilitation); Department of Education (adult education); Department of Conservation and Economic Development (recreation and housing); and the State Treasury (pensions and other financial needs).

Effects on Nursing

Leone reported on trends of staffing hospitals with nurses as urban centers expand. In 388 small communities that built new hospitals between 1947 and 1954, 2 out of every 5 professional nurses employed there came out of retirement. Many other nurses, Leone said, who had been working on other locations came back to live in their own hometowns when the new employment opportunities developed.

The turnover of nurses in suburban hospitals is somewhat less than in urban centers, she said. While the first problem of suburban hospitals is to recruit nurses, once they are recruited they tend to stay in their jobs longer than nurses employed in downtown hospitals. In getting to

their jobs, they prefer not to travel through a downtown area each day to a suburb.

In a study of 1 suburban hospital in Arlington, Va., 2 in Maryland, and the new Washington Hospital Center in the District of Columbia, Leone found that only in Arlington was there a shortage of nurses. "Factors exerting a favorable influence on the acquisition of nurses," Leone said, "were (a) pay increase, (b) aggressive campaign for nurses, (c) newness of hospital and availability of parking space, and (d) need of married nurses to supplement their husbands' incomes. Unfavorable factors were (a) poor location with regard to bus service, (b) lack of school of nursing in the hospital, and (c) low pay."

In order to give adequate service to the mushrooming population, the Arlington Hospital, with its shortage of nurses, makes use of trained aides, clerks, and volunteers.

Effects on Dentistry

Frederich, citing the 1956 survey of dental practice conducted by the bureau of economic research and statistics of the American Dental Association, pointed out that dental care is significantly more available in the suburban business area than in other areas. The urban downtown area follows close behind and slightly ahead of the urban neighborhood area, and the suburban and urban residential areas drop off markedly in availability of dental care.

What are the factors influencing this distribution of dentists? "Established practitioners," Frederich said, "are reluctant to relocate their practices until the inconvenience of their location to patients who have moved away is reflected in pressures from those patients. The choice of a new location is then made between the outlying suburban business district (or neighborhood business district) and the downtown area of the city. The dentist's decision will depend on whether he will follow the family practice into localities where his patients have moved or whether he will make himself convenient to the wage earner who prefers to obtain his dental care near his business location."

"The younger dentists," Frederich said, "tend to locate their practices in newer but established suburban areas which have a higher child

the Federal review or planning stage, are integral parts of a renewal and rehabilitation program. At the same time, the planning organization is developing plans for the protection of sound residential areas which will involve extensive housing inspection and neighborhood studies to insure that environmental conditions adversely affecting the neighborhoods do not develop. "The New Haven program," Andrews observed, "is the result of a combination of strong leadership, active citizen participation, and soundly conceived technical assistance."

In 1957, the Miami-Dade County complex

adopted a charter that, according to Campbell, "for the first time in America established a legal entity designed to handle the entire metropolitan situation through an agency given full responsibility for control of local affairs."

"Where we confront problems that defy boundary lines," Governor Meyner said, "we can develop regional cooperation. And this can be done in health services as it has been done in public education."

Governor Meyner pointed out specific problems that can be best handled through cooperative efforts of different levels of government.

Septic Tank Suburbia

We seem to be on the way to creating a septic tank suburban civilization—a maze of septic tank suburbias. We are doing this because we are now repeating, at least in principle, the mistakes which we formerly permitted in our cities and which we are now spending billions of dollars to correct.

What is happening is, of course, a part of a great transformation—call it explosion—that is taking place in our living patterns.

Because our cities grew painlessly and, in any case, were unfit to handle our automobile way of life, people have been beating it out to the country. At least it once was the countryside. It isn't anymore. The green fields and the old swimming pond have been replaced by hotdog stands, filling stations, superhighways, highway intersections, airports, outdoor movies, indoor skating rinks, and shopping centers. These things have their place, but usually they are in the wrong place.

There isn't a plan, or what plans there are aren't being implemented in relation to the whole. So a few years from now we will be faced with demands for the expenditure of more dollars to straighten out the mess. And when I say "we" I mean the taxpayers.

No one can say we haven't been warned. And no one will be able to blame Uncle Sam. Uncle Sam isn't in any position to police an expanding (or exploding) metropolitan area any more than he can

exercise police or zoning powers in a municipality. And no one wants him to.

What Uncle Sam can do (and has been doing), however, is to fly a warning flag about the growth of septic tank civilization and relate it to the larger problem: the grave need for planning on a metropolitan scale and for action to follow that planning.

The blunt truth is that without effective planning most human enterprises go bankrupt.

One of the tools available to us is the urban planning assistance program, otherwise known as section 701 of the Housing Act of 1954.

Section 701, among other things, authorizes Federal financial aid on a matching basis to official State, metropolitan, or regional planning agencies for the planning of metropolitan and other urban regions.

Some 40 areas are now participating. Others are applying. However, the resources available to section 701 stretch only so far; what I say on this score must not be taken as an open invitation.

What I want to underscore is that *planning* by itself, no matter on how big a scale, is not enough. Plans may be wonderful; they can be supported by bales of statistics and illustrated maps and charts. But something more is necessary to give them meaning.

The plans must be acted on, and the primary responsibility for this lies with the citizens of the regions involved. To put it in the bluntest terms, the money they save will be their own.

—ALBERT M. COLE, *U. S. Housing Administrator*, excerpts from an address to the annual meeting of the Prefabricated Home Manufacturers' Institute, Boca Raton, Fla., March 19, 1958.

Mortality in the 1957-58 Influenza Epidemic

CARL C. DAUER, M.D.

OUTBREAKS of A-prime influenza had scarcely subsided in the United States and Europe late in the spring of 1957 when it was reported that an epidemic of influenza had broken out in Hong Kong about the first part of April. Confirmation that a new strain of type A influenza virus, now referred to as the "Asian" strain, was causing the disease was obtained by the third week of May. The disease was reported to be mild and to have a low mortality, although reports from Manila indicated that the number of deaths from all causes was higher than usual in that city.

Introduction of the new strain of virus into the United States from the Far East probably took place by the last of May 1957, and the first outbreak identified as due to "Asian" influenza began early in June in Newport, R. I. During the summer, the disease in the United States was characterized by a series of localized epidemics, some of them interrelated, in closed groups of teen-age children and young adults. Undoubtedly, dispersal of members of some affected groups to various parts of the country served to seed the population extensively before the end of the summer. During this period, deaths attributed to influenza were few, and the mortality rate from influenza and pneumonia was not higher than expected.

One communitywide epidemic of influenza occurred in Louisiana late in August. In September, when schools in most parts of the coun-

try opened, explosive epidemics began first in high schools and colleges and immediately thereafter in elementary school populations and in preschool children. Incidence in adults was not excessively high. The peak of the epidemic was reached in the third week of October, after which incidence declined throughout November and December. During January, February, and March, the occurrence of influenza was characterized by numerous localized outbreaks, principally in school and other institutional populations.

During the height of the epidemic in October, respiratory disease rates as estimated by the U. S. National Health Survey were about 111 per 1,000 persons per week in the age group 5 to 19 years, 28 per 1,000 under 5 years, 16 per 1,000 in the group aged 20 to 64 years, and about 9 per 1,000 in persons 65 years of age and over.

Data from two sources show the effect of the influenza epidemic on mortality: the numbers of deaths credited to influenza and pneumonia in 108 large cities, reported weekly to the National Office of Vital Statistics, Public Health Service; and the Current Mortality Sample, consisting of a 10 percent sample of all death certificates filed in State departments of health, copies of which are sent each month to the National Office of Vital Statistics (1, 2). These data are provisional; final figures will be available in early 1959.

Influenza and Pneumonia Deaths in 108 Cities

Influenza and pneumonia deaths reported each week from September 1 to March 29 are shown in figure 1 with the 3-year median fig-

Dr. Dauer is medical adviser in the National Office of Vital Statistics of the Public Health Service. Assistance in preparing this report was given by Anne E. Sebastian and Sylvia Osato of the Office's Mortality Analysis Section.

population and a higher level of dental health education than other areas. The dentist is thus able to establish himself more quickly and develop a stable family dental practice, convenient to a highly desirable living environment for his family and himself."

The trends in distribution of dental specialists, he said, are consistent with the distribution of general practitioners. Orthodontists have shown a decided preference for localities with large populations of children and accessibility to good transportation. Frequency of visits and relatively short appointments are not compatible with difficulty of access to the office or inconvenience in transportation.

Oral surgeons tend to occupy central locations with easy access to large numbers of people. They also consider the accessibility of hospitals for the management of the more serious problems.

In the newer trends of distribution of dental services, Frederick observed, there are specific ramifications for those who purchase dental care through personal budget payments (purchase is made through a credit agency) and group purchase plans, and for the indigent.

The budget payment plans, which operate best through centralized administration of its professional and economic aspects, are faced with certain problems imposed by a sprawling population over a wide geographic area, sometimes reaching over State lines.

"As group purchase plans develop and expand, it is reasonable to anticipate that dentists will be attracted to the areas where people covered by such plans live. For access to these plans tends to raise the dental health education of their members and increases their desire to avail themselves of dental care," he said.

The most serious problem that can be expected to develop, according to Frederick, will be in the operation of public assistance welfare programs for dental care. It is reasonable to assume that the suburban shift contains a high percentage of the self-sustaining population, thus resulting in a concentration of lower income and indigent population in the urban area.

If the trend toward the centralization of dental practices in suburban business centers, urban downtown, and neighborhood business areas continues, there will be fewer dentists

available to meet the needs of an expected expanding public assistance welfare health program. To compound this difficulty are the general lack of funds to support the costs of such programs of dental care, particularly for children, and the relatively low level of dental health education of the group. If these conditions are reversed, it seems reasonable to predict that dentists will locate their practices where the demand for care exists, he said.

The changing distribution of population will also have an effect on the special problems of providing dental care to special disease groups. "Certainly," Frederick concluded, "the expansion of the concept of the hospital as a community health center, where all aspects of health care are made available, will have an effect on dental practice."

Conclusion

In 20 short years, Price said, the health of three-fourths of the entire population of the United States will depend upon how well we manage metropolitan services. What kind of air will we be breathing in 1980? he asked. What kind of water will we drink? We are already finding it hard to produce the 200 billion gallons of acceptable water which farms, industries, and cities require daily, he said. How are we going to provide 350 billion gallons a day by 1975?

From now on, Gulick said, most Americans will be born, grow up, live, work, and die in great metropolitan complexes. From now on we are an urbanized community. And something more than the expansion or adumbration of present facilities is needed, he observed. "Improved and expanded water supplies and sewer lines, wider streets, or better housing are excellent ideas, but," Gulick pointed out, "the real things we need are brains, character, drive, organization, and leadership."

Only leadership, Milliken agreed, can reach across the lines of jurisdictions and assist in bringing about cooperative action.

To these remarks, Price added: "Imagination, creativity, minds that can cut through the cobwebs of long-established procedure and find the new method that does the job faster and cheaper—these are the keys to public health progress."

Figure 2. Estimated numbers of new cases of respiratory illnesses¹ and numbers of deaths from influenza and pneumonia, in 108 large cities, by week.

¹ U. S. National Health Survey estimates.

tional Health Survey and the numbers of deaths from influenza and pneumonia reported in 108 cities are shown in figure 2. As would be expected, morbidity rates from respiratory disease began to rise about 3 weeks before there was any apparent rise in mortality from influenza and pneumonia in the large cities. The peak in morbidity was also reached about 3 weeks prior to that for mortality. However, the second rise in mortality was not preceded by any rise in incidence of cases of respiratory disease. As a matter of fact, no rise in incidence was apparent until about 4 weeks after

the beginning of the secondary rise in mortality, and that increase in incidence was moderate.

During the fall of 1957, deaths from influenza and pneumonia were above expected levels in the cities of all regions, but the excess was less pronounced in the West South Central, Mountain, and Pacific groups of cities. Such geographic variations have been common in previous epidemics. The second rise in mortality during January, February, and March 1958 was greater in the East North Central and West South Central cities. It was smaller in the West North Central and South Atlantic,

ures for 1954-56. These data show that mortality rose well above expected figures and reached a peak early in November, receding in December and early January 1958 to a level which remained above normal expectancy in December and early January. Another rise in mortality began about the middle of January; it reached a peak about the first of March.

There was a remarkable similarity in the trends of mortality from influenza and pneumonia in the 108 cities of the United States and the 160 large towns of England and Wales as reported in the Weekly Influenza Statement issued by the British Ministry of Health (fig. 1). In both countries, there were two peaks of mortality, but the early peak in the United States was reached 4 weeks later than in Great Britain. If the data are plotted so

that the early peaks in each country are superimposed, the similarities are even more striking. Each group, for example, reached a peak in 6 weeks and declined for a similar period of time. Mortality, however, continued to rise for a longer period during the second rise in the United States.

A total of 14,470 deaths from bronchitis was also reported in England and Wales from the first of September 1957 to March 8, 1958. Whether these correspond to any of the bronchopneumonia deaths reported in the United States or some other entity is not known. There were many more such deaths in England and Wales during the second rise of mortality than from influenza and pneumonia.

The estimated numbers of new cases of upper respiratory illness reported by the U. S. Na-

Figure 1. Numbers of deaths from influenza and pneumonia reported weekly in 108 large cities in the United States and 160 large towns in England and Wales, with the median for the period 1954 through 1956.

Figure 3. Estimated death rates from influenza and pneumonia, by month, 1951, 1953, and 1957.

the excess credited to this cause. In recent years, only about a quarter of the excess mortality resulting from influenza epidemics has been attributed to influenza and pneumonia.

In measuring the effects of the 1957-58 epidemic, excess mortality for the country as a whole was obtained by subtracting from the number of deaths during the period September 1957 to March 1958, those reported during the comparable period in the previous year. The 1956-57 period was considered normal because there was little influenza and the numbers of deaths reported were not greatly different from the 3-year (1954-56) mean and median numbers.

Since increases in mortality during influenza epidemics of the past decade or two have not been solely caused by influenza and pneumonia,

data showing excess mortality from other causes are included. The estimated numbers for these categories are shown in table 1 by months from September 1957 through March 1958, and, for comparison, the estimated numbers for the previous year are given as well. The differences between the data for the two periods are shown in table 2. In the same table, these differences or excesses are also expressed as the excess number of deaths per 100,000 population for each month. They should not be confused with mortality rates for the various categories.

The excess mortality for the country as a whole as well as numbers of influenza and pneumonia deaths for the cities occurred in two phases or "waves." The first rose and fell with the explosive epidemic in September, Oc-

and was absent in the Mountain and Pacific cities. In two areas, the East and West South Central, the numbers of deaths from influenza and pneumonia in January and February 1958 equaled or exceeded those reported in October and November 1957. There were equally wide variations from city to city within most of the geographic divisions, that is, some cities reported more than the number of expected deaths from influenza and pneumonia in the fall, some during the winter, and others had significant increases in both the fall and the winter.

Mortality in the Nation

When mortality rates from influenza and pneumonia in the 1957-58 epidemic are compared with those for certain other recent epidemics, it is found that the death rates in 1957-58 were not excessively high, as shown in figure 3. The peak in the 1953 epidemic was reached in February when the mortality rate from influenza and pneumonia was 75.9 per 100,000 population, and in 1951 the peak was reached in March with a rate of 59.8. The peak in 1957-58 was reached in November when the rate was 66.6 or about midway between 1951 and 1953. In 1943, the peak month was

February when the death rate from influenza and pneumonia was 94 per 100,000 population. However, the period of increased mortality extended over a longer period of time in 1957-58—about 6 months, compared with the usual 3 to 4 months.

Excess Mortality

The number of deaths above that expected during a nonepidemic period, or the excess mortality, has been used by Collins to measure the effects of epidemics of influenza (3, 4). He has used this method since approximately 1930 to measure the size of epidemics and has shown that 21 separate ones have occurred since 1918-19. By using data from selected cities, Collins showed that excess mortality from influenza and pneumonia in these cities amounted to 99.3 per 100,000 population in 1920, 44.4 in 1928-29, 18.4 in 1936-37, 14.4 in 1943, 3.8 in 1951, and 6.9 in 1953. He also demonstrated that during influenza epidemics there had been an excess in mortality from causes other than influenza and pneumonia. This excess was mainly from cardiovascular diseases. Since 1918 when about 95 percent of the excess mortality was credited to influenza and pneumonia, there has been a gradual decrease in the proportion of

Age Distribution of Deaths

The age distribution of deaths from influenza and pneumonia is available for the last 5 months of 1957. These have been compared with those for a similar period of 1956 (see table 3). These data show that, while all age groups experienced some increase in mortality rates, the highest rate per 100,000 population was in the very young age group under 1 year, and in persons 65 years of age and over. There was a greater percentage increase in the rates in the age groups from 1 to 64 years, but this was not sufficient to change the contour of the curve of influenza and pneumonia mortality seen in recent epidemics.

The numbers of deaths by age groups in excess of those for the previous year are shown for all causes in table 4. Two periods of time, corresponding to the two phases of the influenza epidemic, are shown. The excess is also expressed as the number of deaths per 100,000 population above that for the previous year. These data show that 80 percent of the excess deaths from September to December, inclusive, occurred among persons above the age of 54 years. From January to March, inclusive, the proportion was 85 percent for the same age group. The proportions of the excess which occurred in infants were 3 and 2 percent, respectively, for the two periods of time. These data point up the vulnerability of persons in the older age groups during the recent influenza epidemic. The excess mor-

tality in infants was relatively small and, in children and young adults, slight.

Discussion

The recent epidemic caused by the Asian strain of type A influenza virus appears to have been similar to the 1918-19 epidemic with respect to its seasonal occurrence. Both were characterized by localized outbreaks prior to the explosive type of infection early in the fall. Both were milder in the following winter months.

The recent epidemic differed from that of 1918-19 in that mortality this time was lower; most of the excess deaths were credited to cardiovascular disease, and deaths were relatively more common in older persons, in contrast with high mortality principally from influenza and pneumonia in young adults in 1918-19.

The epidemic of "Asian" influenza was similar in most respects to others caused by the A-prime strains during the past decade in which mortality was not excessively high; most of the excess deaths occurred in older persons; and a large proportion of excess deaths was credited to cardiovascular diseases. However, the 1957-58 epidemic differed in that the main or explosive part occurred early in the fall rather than in the winter, it was preceded by a series of localized outbreaks, and it was followed by a secondary rise in mortality with little evidence of widespread infection.

The very large excess in numbers of deaths

Table 2. Excess number of deaths by cause from September 1957 through March 1958 as compared with comparable periods in 1956-57

Month	All causes		Cardiovascular diseases		Influenza and pneumonia		All other causes	
	Number	Rate ¹	Number	Rate ¹	Number	Rate ¹	Number	Rate ¹
September.....	5,090	2.9	2,620	1.5	820	0.5	1,650	1.0
October.....	18,780	10.9	9,470	5.5	4,430	2.6	4,880	2.8
November.....	16,100	9.3	5,430	3.2	5,290	3.0	5,380	3.1
December.....	13,540	7.8	7,330	4.2	2,640	1.5	3,570	2.1
January.....	6,810	3.9	3,720	2.2	2,270	1.3	820	.5
February.....	15,430	8.9	11,410	6.6	2,840	1.6	1,180	.7
March.....	2,290	1.3	536	.3	2,000	1.2	-240	-.1

¹ Excess number per 100,000 population.

tober, and November 1957, and the second occurred in January, February, and March 1958 during a period of localized outbreaks, mainly in schools and institutional populations.

The greatest excess mortality from all causes occurred in October 1957, when incidence of respiratory illness was at its height. This was due mainly to the fact that deaths from cardiovascular diseases were excessively high. On the other hand, the greatest excess in influenza and pneumonia deaths occurred in November, coinciding with the peak in numbers of deaths from this cause reported by the 108 large cities. During this same period, excess deaths from causes other than cardiovascular diseases and influenza and pneumonia were highest.

Mortality during the second phase, during January, February, and March 1958, rose to a high level principally in the category of cardiovascular diseases. In February, the excess

number for this disease category was 22 percent above the excess for the preceding October, while excess deaths from influenza were well below those reported in November. Deaths from all other causes were also well below the level reached in November.

While excess mortality from all causes during the last 4 months of 1957 amounted to 53,510 deaths, the effect on the general death rate of the United States was not striking. The provisional crude rate for 1957 was 9.6 based on the 10 percent sample of deaths as compared with 9.4 in 1956, or an increase of 2.1 percent. If the excess number of deaths during the last 4 months of the year were subtracted from the estimated total for 1957, the rate would have been about 9.3 per 1,000 which would have been lower than that for the previous year.

Table 3. Estimated death rates for influenza and pneumonia, by age group, for the period August through December in 1957 and in 1956

	All ages	Under 1 year	1-24 years	25-44 years	45-64 years	65 and over

Despite both administrative and technical difficulties, public health officials have many resources to draw upon as they move to limit damage to the Nation's health by nuclear radiations.

Administrative Aspects of Nuclear Energy

E. C. ANDERSON, M.S.

THE PUBLIC HEALTH administrator looking at nuclear energy finds himself confronted with some unique problems. Some of these stem from the nature of radiation and its biological effects, and some from existing professional, administrative, and legal relationships, over which he has little control.

One unique aspect of radiation protection is that it presents an opportunity, if not a necessity, to develop special practical preventive measures beforehand, in anticipation of contamination, to prevent serious exposures of large populations. In the past, public health has been permitted to indulge in occasional lapses. The results of its failures have often inspired greater and stronger preventive measures. With respect to radiation, however, the penalty may be irrevocable and possibly final.

Nature of Radiation Hazards

There are both an abundance of data and a complete lack of assurance as to the nature and sources of the health hazards of radiation associated with nuclear energy, with the operation and products of nuclear reactors. While the precise biological effects of radiation are as yet uncertain, the current scientific consensus is that any dose of radiation is harmful to some

degree. Therefore, any unnecessary exposure should be avoided. In other words, doses should be kept at a minimum, consistent with the benefit that will be gained from radiation.

A second general premise is that damage is irreversible and cumulative. Hence, all sources of exposure of individuals or populations must be considered, irrespective of their nature. Related to this aspect is the difference between two types of exposure: external, which results primarily from gamma and X-rays, and internal, from ingested or inhaled radioactive materials.

Also to be considered are two general types of effects: the short-term, acute effect that one normally associates with high dose rates resulting from an accident or a weapon; and the long-term, cumulative effect of low-level doses, usually associated with normal, civilian uses of nuclear energy but including even those slight but chronic doses associated with the widespread fallout from weapons testing.

Sources of Radiation

For complete perspective on nuclear energy, the administrator first needs to look at all the sources of radiation.

Everyone is and always has been exposed to natural background radiation. This radiation varies with geographic location, elevation, and other factors and includes both internal (natural radium, radioactive potassium, breathed radon and thoron, for example) and external

Mr. Anderson is chief of the Special Projects Branch, Division of Radiological Health, Public Health Service.

from all causes, and, especially from cardiovascular diseases, in January, February, and March 1958 is difficult to explain. There was no evidence of widespread occurrence of influenza at that time, and excess mortality from influenza and pneumonia was small compared with that of the previous October and November. The actual number of deaths from influenza and pneumonia was 2,000 less in February 1958, the peak month, than it was in November 1957 and the number which would be expected to occur was about 1,000 more in February than in November. Consequently, the excess was relatively small for this category. Persons in the older age groups, among whom most of the deaths occurred, may have had during this period respiratory infections that were difficult to recognize, possibly the reason why the majority of the deaths were credited to cardiovascular diseases. The suggestion also has been made that many of those who died in January and February had been weakened by attacks of influenza in the fall of 1957. Since a number of deaths during the epidemic in the fall were caused by staphylococcal pneumonia, the possibility that the increase in deaths in January, February, and March was due to this infection has also been proposed. Information from certain hospital centers and mortality data do not support this hypothesis. The reason for the increase in mortality during the last part of the winter remains unexplained.

The data presented in this report indicate

very clearly that the total impact of the 1957-58 influenza epidemic on mortality cannot be approximated if only deaths credited to influenza and pneumonia are taken into consideration. The data show that the increase in the number of deaths credited to cardiovascular diseases accounts for approximately one-half of the total excess mortality. This is not surprising, since most of the deaths occurred in older persons, many of whom would be expected to have some evidence of cardiovascular pathology.

CDC Courses in Insect and Rodent Control

Refresher training in insect and rodent control will be offered at the Communicable Disease Center, Atlanta, Ga., during September 15, 1958, through June 1959, according to the following schedule:

Insect control. September 15-26.

Rodent control. September 29-October 10.

Mosquito control. November 2-7.

Biology and identification of arthropods of public health importance. January 12-23.

Epidemiology and control of vector-borne diseases. February 16-20.

Insect and rodent control. June 1-12.

There are no tuition or laboratory fees for the courses. Students will be accepted from State and local health departments, the Armed Forces, and other organizations concerned with insect or rodent control. Qualified students from other countries will be accepted and given opportunity to study vectors of important diseases.

Application forms may be obtained from the Chief, Training Branch, Communicable Disease Center, Public Health Service, 50 Seventh Street, NE., Atlanta 23, Ga.

restrictions on many activities and much of the information related to radiation. Whatever the reasons, AEC is issuing licenses to and establishing health and safety criteria for private industries and users falling within the scope of the Atomic Energy Act of 1954.

This situation gives rise to a number of questions. In this country, the States have as one of their constitutional powers the protection of the public health. The question has been raised as to whether the licensing activity of AEC has preempted from the States the right to exercise control over AEC licensees. This specific question may be answered by a court decision or by legislation. The Atomic Energy Commission is currently proposing an amendment to the Atomic Energy Act which would, with certain reservations, recognize the States' right to exercise their police powers over nuclear energy. In any event, at this moment the respective authority of the States and the Federal Government in the atomic energy field is not clearly defined.

At present, both Federal and State governments have an opportunity to reduce the potential hazard. From a health standpoint, it makes no difference whether ionizing radiation comes from an X-ray machine or radium under State jurisdiction or radioactive substances under the control of AEC or foreign governments. The public health agency must consider all of these sources of radiation exposure in administering a radiation control program, even though it cannot assert complete control over manmade sources of radiation. If a State has already proceeded to regulate sources of radiation within its jurisdiction, it is in a far better position to challenge other radiation sources. Meanwhile, the public must look to higher authorities also, and not only to AEC. The AEC cannot legally exercise control over sources other than special nuclear materials, byproduct materials, and utilization and production facilities. Others have responsibility related to transportation of radioactive materials, weapons tests, and naturally occurring and machine-made radiation and radionuclides.

Resources Available

The public health administrator will find that there are a number of resources available to

guide and assist in developing and carrying out a radiation protection program.

While the basic rule in radiation protection is that all unnecessary exposure to radiation should be avoided and that each exposure must be justified on the basis of benefit gained, one must also have a guide as to levels of dose and concentrations of radioactivity which call for special consideration in the light of assumed benefits. The parent group for developing recommendations on maximum permissible doses and concentrations of radioactivity in the environment is the International Commission on Radiological Protection. This body, composed of professional and scientific members from many countries, establishes basic standards and criteria which are the foundation of recommended standards, laws, and regulations.

In the United States, basic radiation protection standards are drawn up by the National Committee on Radiation Protection and Measurement, composed of representatives from a broad range of professional and scientific organizations. The committee operates through 11 subcommittees whose recommendations are published by the National Bureau of Standards. The publications of broadest interest to the public health agency are Handbook 52, Maximum Permissible Amounts of Radioisotopes in the Human Body and Maximum Permissible Concentrations in Air and Water, and Handbook 59, Permissible Dose From External Sources of Ionizing Radiation. Others of the handbooks deal with more specific subjects.

The American Standards Association has created a Nuclear Standards Board, and has established under this board seven projects dealing with various phases of nuclear energy. Of particular interest to the health professions are projects N1, Glossary of Terms in Nuclear Science and Technology; N2, General and Administrative Standards for Nuclear Energy; N3, Nuclear Instruments; N6, Reactor Hazards; and N7, Radiation Protection. To date, the Nuclear Standards Board has approved, as an American standard, the Glossary of Terms in Nuclear Science and Technology, published in 1957 by the American Society of Mechanical Engineers. No other standards have been published as yet under this board but committees are active in their development.

exposures. While not practically controllable, it contributes substantially to an individual's total lifetime exposure. It has been used as a baseline from which to compute maximum permissible doses.

Medical and dental uses of X-ray; medical, industrial, and research uses of radium and radionuclides; and industrial uses of X-ray are well-known controllable sources of radiation exposure.

The major prospective source of radioactive material and potential radiation dose, however, is the nuclear reactor. Reactors are becoming increasingly common as research tools in medical, educational, and industrial institutions and establishments. Power reactors for vessel propulsion have been installed by the Navy and are being applied to merchant vessels. The commercial power reactor at Shippingport, Pa., is now in operation, and many more power reactors are under development. We may expect a wide variety of operating reactors in and near populated centers within the next decade.

All reactors produce certain radioactive wastes. Such liquid, gaseous, and solid radioactive materials are usually treated or segregated at the reactor site or diluted in discharge. Extremely radioactive spent fuel must be isolated or removed from the reactor site for treatment at central chemical processing plants, as there is no way to reduce the radioactivity or shorten its duration. The major source of radioactivity is the fuel, which builds up radionuclides as a result of nuclear fission until fission is no longer practical and the fuel is "spent." To segregate fission products and recover fissionable fuels, spent fuel elements are processed at special plants owned by the Atomic Energy Commission and located on Federal reservations. AEC has requested proposals from private industry for the construction and operation of additional plants for chemical processing of spent fuel. Under investigation also is the possibility of continuous treatment of liquid fuels at the reactor site.

Wherever treatment is carried on, it is necessary to deal with treatment and disposition of low-level wastes; transportation of either highly radioactive spent fuel or fission products segregated from the fuel; and ultimate disposition of millions of curies of fission prod-

ucts, now mostly stored in tanks underground. To recapitulate, reactors present a special challenge to air pollution control, industrial hygiene, water pollution control, solid waste management, transportation of extremely hazardous materials, and, above all, high-level waste disposition.

In addition to the hazards related to normal reactor operation, an accident, or accidental discharge of radioactivity, could produce immediate, acute contamination of areas outside the reactor site. The accident hazard cannot be fully evaluated, for lack of experience. It is real enough, however, to be causing concern to industry, insurance companies, and Congress. The consensus seems to be that there is no danger that a reactor will produce a nuclear explosion, but that a chemical or steam explosion in a reactor plant could seriously contaminate several square miles.

The final significant health hazard associated with nuclear energy is that resulting from military testing of nuclear devices and weapons. Tests by the United States, the U.S.S.R., and the British Commonwealth all have added measurably to background radiation. Except in the area surrounding the Nevada Test Site, tests have not added detectably to the gamma background as measured on a G-M survey meter. They have, however, added to the airborne radioactivity and to radioactive fallout, rainout, and washout. Health authorities are therefore less concerned with fallout as a source of background radiation than with the possible assimilation and concentration of long-lived radionuclides in all living organisms, with the prospect of injury from their chronic presence in human tissue. The full significance of this fallout is not yet known.

Administration and Standards

Unlike other health hazards, many sources of radiation produced by nuclear energy are beyond the direct jurisdiction of the local or State government. The Federal Government is exercising an unusual influence on both the development and control of nuclear energy. There are, of course, many reasons for this, such as the participation of the AEC in weapons development, national security implications, and

ment of programs to accelerate the use of radionuclides and applied radiation in industry, agriculture, and medicine, and to encourage industrial production and distribution of radionuclides and other radiation sources. In addition, it administers AEC's program for granting access to restricted data pertaining to civilian uses of nuclear energy.

The Division of Inspection is responsible for inspecting license holders to determine compliance with the terms of their licenses. As a general rule inspectors from the division will work with State agencies or keep them advised of their activities.

The basic function of the Public Health Service is to strengthen the capacity of the States to use their powers for the protection and promotion of the public health through radiation protection. The Service also performs activities beyond the powers, competence, or financial ability of the individual States. Thus the functions of the Service may be divided into the following major components:

- Assistance to States: training, consultation, and technical assistance.
- Dealing with interstate problems: pollution of air or interstate streams.
- Collaboration with other Federal agencies or scientific groups on problems which have a health component and need to be dealt with at the national level: exposure tolerances, safe transport, uniform reporting, model legislation, and codes, for example.
- Research, development, and research training: in PHS installations and by extramural grants and stipends.
- Public information.
- Radiological intelligence: nationwide collection, analysis, and dissemination of data useful in conducting radiological health programs.

The Department of Agriculture has a general interest in radiological health to the extent that individuals who produce, handle, process, and market farm products, and the animals and plants upon which this country depends for food, fiber, and other agricultural materials, are affected adversely by radioactive materials. Adverse effects include not only the impairment of health and comfort but the retardation of normal growth and development and accumula-

tion of radionuclides in animals or plant products destined for the food market.

In the Department of Commerce, the National Bureau of Standards is concerned with the measurement of radiation dosages, and physical methods of assessment and control through proper design. The Bureau also sponsors the National Committee on Radiation Protection and Measurement, which is the major authority in the establishment of radiation protection standards in the United States.

The Weather Bureau constitutes an important resource in providing an understanding of the dynamics of natural and manmade radioactivity in the atmosphere. Its forecasting services predict local meteorologic conditions which guide design and operations in minimizing radiation exposure.

The Department of Defense's interests are related to the development, transportation, and detonation of nuclear weapons in peace and war; the effects of nuclear war; and the military applications of nuclear energy for propulsion, food preservation, and packaged power. Operators of military sources of nuclear energy tend to be of ages at which genetic injury has implications more grave than it does for the average industrial or medical users of radiation.

The National Science Foundation has a direct interest in radiation stemming from its statutory responsibilities. Many problems of basic physics, biophysics, genetics, and biology must be solved before a truly scientific approach can be made to the development of health standards suitable for an economy utilizing nuclear energy extensively. Certain grants and fellowships awarded by the National Science Foundation encourage fundamental research in the field of radiological health.

The Food and Drug Administration is interested in the potential contamination of foodstuffs and the assimilation of radioisotopes of elements naturally absorbed by crops grown for food. It is also interested in the effects of radiation used to process foods.

The Children's Bureau of the Social Security Administration has an interest in radiation as it affects the health of children.

The Office of Education's interest lies in the need for training of personnel in nuclear energy and in radiological health.

The American Public Health Association has appointed a committee to work on radiation with the Association of State and Territorial Health Officers and the Conference of State Sanitary Engineers. This committee has prepared a policy statement, model legislation, and an orientation pamphlet, and is developing an administrative guide.

The Council of State Governments has also developed and recommended State legislation dealing with nuclear energy. This suggested legislation encompasses all aspects of the nuclear energy industry rather than health protection alone.

As mentioned before, the Atomic Energy Commission has established health and safety criteria applicable to licensees under the Atomic Energy Act of 1954. These have been published as Standards for Protection Against Radiation (10 CFR 20). While these apply only to establishments under the control of the AEC, they represent the only specific control in States that have adopted no laws or regulations to control radiation hazards. The regulations are based on but are not identical with recommendations of the National Committee on Radiation Protection and Measurement. Some States use these regulations as advisory guides in the absence of specific State regulations, while others use them as models in developing State regulations. The AEC regulations do not cover all sources of radiation, however, and are not entirely applicable to State control.

Role of the Federal Agencies

The Federal Government exercises a greater influence and plays a more direct role in radiation protection than in any other public health program.

The greatest part of the Federal resources is being devoted to military applications. In order to monitor the products of weapons tests, the Public Health Service, under agreement with the Atomic Energy Commission, operates a radiation surveillance network composed of 43 stations equipped to collect air and rain samples and take daily gamma readings. These stations, which also estimate the amount of radioactivity in particulate matter collected

from air samples, are operated by State and local health department personnel. Samples are sent to a PHS laboratory in Washington, D. C., for final counting. Results of the surveillance estimates are immediately made available to the State health officers concerned, and weekly reports of the laboratory are sent to all State health officers.

A Medical Liaison Officer Network, composed of medical personnel from the Public Health Service and State and local health departments, also under agreement with AEC, is available to investigate reports of injury allegedly due to fallout.

With respect to civilian applications of nuclear energy, the AEC plays the Federal Government's major role in radiation protection. The operating arms of AEC dealing with civilian uses of nuclear energy are the Division of Licensing and Regulation, the Office of Industrial Development, and the Division of Inspection.

The Division of Licensing and Regulation handles all regulatory matters, other than inspection activities. Among these are the preparation, issuance, and administration of regulations, issuance of licenses, development of standards, guides, and codes for the safe design, containment, and operation of reactors, and evaluation of the safety aspects of all proposed reactors. Included is responsibility for developing regulations and licensing procedures for the safe handling and use of radionuclides, source material, and special nuclear material.

The division is also responsible for assessing the requirements of the private nuclear energy industry for nuclear materials such as uranium, thorium, and plutonium, and for administering the allocation and distribution of these nuclear materials to licensees.

The Office of Industrial Development, in consultation with other offices and divisions, develops AEC policy and procedures for encouraging the growth and development of peaceful uses of atomic energy. It advises private groups on opportunities open to them. It seeks to identify industrial activities, including those now performed by AEC, which lend themselves to private undertakings, and assists in encouraging industry to enter these fields.

A major function of the office is the develop-

Detailed regulations can best be considered after the needs of the State have been defined. National Bureau of Standards Handbook 61, Regulation of Radiation Exposure by Legislative Means, forms as good a basis as is currently available for the development of such regulations. However, this handbook was not designed to be adopted in toto or verbatim, but to be used as a guide. At the same time, all regulations must be based on the same standards, the recommendations of the National Committee on Radiation Protection and Measurement, which is uniquely qualified to appraise radiation hazards. An impossible situation would develop if individual States and AEC adopted conflicting standards.

The specific organization within a State agency for radiological health will vary, depending on a number of factors. If a significant problem exists in a State, it appears advantageous to designate a person or a specific ad-

ministrative unit as the central point for radiological health. This person or unit may then be the principal point of contact with other interested agencies and can furnish technical assistance to other programs.

In some States, it is perfectly possible that a satisfactory program can be established by adding to each program, such as water pollution control, air pollution control, and milk and food sanitation, the necessary radiation protection responsibilities. This method would be particularly likely if the only radiation protection required were, for example, related to occupational exposure.

A program of radiation protection is complex both technically and administratively. However, with their wealth of experience in public health and with the resources available to assist them, health officials are in a position to move forward in this field as they have in others.

Institute of Veterinary Public Health Practice

The first institute of veterinary public health practice, to be held October 6-9, 1958, at the School of Public Health, University of Michigan, will stress the use of veterinary resources in disciplines of human health.

Speakers include Margaret G. Arnstein, Dr. Gaylord Anderson, Dr. James H. Steele, Dr. H. J. Stafseth, Dr. W. W. Armistead, Dr. T. J. Francis, Jr., Dr. Mark W. Allam, Dr. Albert E. Heustis, Dr. E. H. Cushing, and Dr. R. E. Rebrassier, among a number of others.

Topics scheduled for discussion are the possible contributions of veterinarians and veterinary research to such fields as nursing, geriatrics, mental illness, human cancer, heart disease, industrial hygiene, and radiation hazards.

In separate working sessions under the leadership of five section committees, participants will discuss the most effective ways of using public health veterinarians, private practitioners, regulatory officials, and industrial veterinarians in official and voluntary health programs. The conclusions will be presented in general session.

For more information write to H. E. Miller, Director, Continued Education, School of Public Health, University of Michigan, 109 South Observatory Street, Ann Arbor, Mich.

The Department of Labor is interested in protecting employees exposed occupationally to radiation.

Role of State and Local Governments

Much of the work of the 48 State health departments is advisory and consultative. They establish standards and program policies which are used as guides by local health departments, to whom they have delegated much of the responsibility for applying protective measures. They also provide technical services which are beyond the resources of the local health department.

The States have universally retained final authority with respect to approval of plans for construction and operation of public water supplies, treatment and disposal of sewage and industrial wastes, and control of water pollution. Many are now becoming interested in the control of air pollution. Many also review and approve building plans to assure that the industrial hazards to health are adequately controlled before operations are started.

A pattern may now be developing in the relationship between the Government-sponsored nuclear energy industry and the State agencies. It is urgently desired that the industry be supplied with design and operational health and safety criteria which permit the least restrictions on economy of operation. These, in part, are furnished by the AEC Standards for Protection Against Radiation, which establishes the maximum operational levels acceptable to AEC. State health agencies, with a broad concept of radiological health, are concerned with the total radiation exposure of the population, no matter what the sources of exposure might be. At present, for example, the principal sources of exposure to radiation of a community are, probably, natural background radiation and medical diagnostic X-ray. Health agencies, if they desire to restrict public exposures to a practical minimum, will admit additional sources of radiation only when it is demonstrable that little increase is anticipated and that the possibility of individual hazard is minimized by adequate control procedures.

Obviously, the workload facing the inspection division of the AEC is sizable. The need

for time and experienced personnel will impede its development of a nationwide system designed to relate the levels and effects of radiation to the multitude of public health matters. The only experts today on integrating the nuclear industry into local situations are the State and local people who deal with public health matters exclusively. The Atomic Energy Commission and the nuclear industry need the assistance of the States and their ability, knowledge, and authority, even as the States need the specialized skills in organizations sponsored by the Federal Government.

The Atomic Energy Commission, by means of its proposed health and safety standards, is showing commendable concern over the eventual effects on the public health that radioactive material may have. No matter how intensive AEC's inspection of its contractors and licensees may be, however, its actions cannot be construed as the practice of public health, although they may make substantial contributions. The responsibility for safeguarding the public health, in any event, still lies with the States and the State and local health agencies.

State Programing

The States, in this position, are looking to their individual problems and equipping themselves to meet them. Their first action in going into the field of radiological health is to seek technical competence in staff. Ideally, they would prefer 1 or more years of graduate training for 1 or more staff members, depending on the needs within the State. Alternatively, and on an interim basis, competence is cultivated in present staff members working on programs, such as water pollution control, associated with nuclear energy. Such staff members may attend short, topical courses of the type offered by the Public Health Service at the Robert A. Taft Sanitary Engineering Center in Cincinnati.

Another early step is to define the needs. Some agencies have utilized existing programs to secure information on radiation sources. Others have enacted legislation specifically authorizing State agencies to conduct a radiation survey. Still others require all users of ionizing radiation to register.

Courses sponsored by the health agencies of five Michigan counties gave nursing home personnel new understanding and a new outlook on their jobs.

Saginaw's Training Courses for Nursing Home Staffs

RALPH E. LEWIS, M.P.H.

FORESIGHTED nursing home operators, realizing that even years of practical experience may not be adequate in coping with the various behavior problems of aged patients, are seeking training for themselves and their employees.

As they see the elderly patients in their homes become more withdrawn, less self-sufficient, and less cooperative, the operators recognize that these people need skilled assistance. And operators are acknowledging that nursing home personnel need training and specialized study to compete successfully in a rapidly expanding field of enterprise.

This was the case in Saginaw County, Mich. In the fall of 1956 the need for some such training was discussed at a meeting of the Saginaw Valley Community Health Services, Inc., a corporation organized in 1952 by the public health agencies of Saginaw, Bay, Midland, Isabella, and Tuscola Counties to provide public health services on a regional basis. Community Health Services then offered a plan for a training course to the Saginaw Association of Approved Nursing Homes. Later several members of the association discussed the need for training with officials of the Saginaw County Health Department.

Mr. Lewis, program coordinator for the courses he describes, is health educator of the Saginaw County Health Department, Saginaw, Mich.

Because an area wider than Saginaw County was concerned, the matter was submitted to the board of directors of the Saginaw Valley Community Health Services. After some discussion the board authorized a committee of the health officers of the member counties to explore the possibilities of training nursing home personnel.

The health officers invited representatives from the area's nursing homes, local and State health departments, Saginaw County Hospital, and the University of Michigan's Division of Gerontology and School of Public Health to form an advisory committee to determine the feasibility of developing some type of training for the staffs of nursing homes in their five-county area. Advisory committee members with interests and associations in nursing home administration in Michigan and the Saginaw Valley were appointed.

The committee had many questions. Was a training program really needed? Who would be eligible to attend this training? What subject matter should be covered? Who would the instructors be? How lengthy a course was necessary? Would a single course or successive courses be advisable?

The advisory committee met with the area's nursing home administrators at a regional meeting, visited some of the homes, and talked with employees, patients, and administrators to find answers to these questions.

After the Earthquakes

Continued shocks, horror, grief, hunger, and bitter cold nights virtually paralyzed the people after a series of earthquakes in the provinces of Kermanshah and Hamadan in western Iran in December 1957.

An avalanche of vague, conflicting rumors reached the health department in Kermanshah after the quakes. The more serious seemed to generate from Farsinage, Assadabad, Fash, and Sarab-Sahneh. We dispatched a doctor and a nursing team with first aid supplies, medications, and powdered milk to each location.

I visited Sarab-Sahneh and Fash and later went to the Assadabad area where I found our team in Sirvan, a badly devastated village. We borrowed a tent from the army troops sent there to assist in relief work, and set up a first aid shelter. Nurses prepared hot milk in a salvaged *deeg*, or pot, for the children and mothers. They gulped the milk hungrily; it was the first real nourishment they had had since the disaster some 30 hours before. They had devoted the previous daylight hours to burying more than 40 people killed in the quakes, and the villagers had neither time nor facilities to feed their children or themselves.

From Teheran the U. S. Operations Mission headquarters sent three trucks loaded with 5,000 kilograms of dried milk, perchlorine, and DDT dusting powder. The head of the General Department of Public Health of Iran came from the capital with a crew of engineers, nurses, nurse aides, and sanitary aides. They brought tents, blankets, dried milk, vaccines, biological supplies, DDT, and bandages to the stricken areas.

Luckily the water supply was not damaged; almost all the villages used mountain springs, which, if affected at all, regained their original quality and volume within a few hours after the tremors.

Sanitary aides worked to provide safe excreta disposal. Under the chaotic conditions, conservative

farmers were reluctant to use the unfamiliar latrines. In the press of construction, the privies were not always built in accordance with religious requirements, not always equipped with elevated foot rests, and sometimes lacked even a solid roof.

However, a mere 13 sanitary aides with leadership, a bit of salesmanship, a measure of health education, and a willingness to work with their own hands dotted the landscape with sanitary latrines. Sanitary aide Rostenpour alone was instrumental in building 65 at Farsinage.

Chilean Plan

Chile may be the first nation in the world to have at each of its normal schools a faculty member trained in public health.

The Ministry of Education has arranged to have 5 professors from teacher training institutions study at the University of Chile's School of Public Health each year until all 15 of the country's normal schools have a faculty member so trained. A member of the ministry's staff, who is already studying at the school, will develop a department of health education to serve the schools of Chile.

Typhoid in Pusan

More than 30,000 people visited an exhibit entitled "Rodents and the Damage They Cause" last winter in Pusan, Korea. The exhibition in the Republic of Korea Information Building and the distribution of a million packages of rodenticide and 50,000 rat traps were part of a rodent eradication campaign.

Pusan had an outbreak of typhoid fever, with 153 cases reported in less than 3 months. To curb transmission of the agent, we cleaned and chlorinated wells and stressed the need to boil drinking water. Efforts to give typhoid vaccinations, particularly to people in the refugee areas, however, met with considerable resistance.

—ALFRED S. LAZARUS, PH.D., *acting chief, Health and Sanitation Division, U. S. Operations Mission, Korea.*

ant hospital superintendent. She considered the qualifications of a good administrator and an efficient employee and the importance of their attitudes toward patients.

3. "Bed Care of the Long-Term Patient," was discussed by a registered nurse who is an instructor of nurses. She demonstrated bed-care methods and displayed materials to make the patient's life more comfortable and enjoyable and the employee's job easier and more efficient.

4. A lecture on the "Medical Needs of the Aged and Chronically Ill," presented by a physician, emphasized the physical, mental, and emotional changes that take place as a person grows older. He described some of the physical and mental needs of the aged and chronically ill, and told how a nursing home staff can assist the physician in taking care of individual patients.

5. A session devoted to "Rehabilitation," designed to introduce the two succeeding sessions on physical therapy and occupational therapy, was also conducted by a physician. He reviewed the newer philosophies of rehabilitation, its aim and function in working with the aged, long-term patient. He also showed the film "Still Going Places," which dramatically illustrates practical ways to help chronically ill or acutely disabled patients of advanced years to live useful, self-sufficient lives.

6. "Physical Therapy," conducted by a registered physical therapist, included a brief historical review and demonstrations of various methods and techniques of physical therapy which can be effectively used with specific types of patients.

7. During the "Occupational Therapy and Hobbycraft" session, motivation and techniques in introducing occupational therapy were discussed, new ideas in the field were explained, and sources of supplies were listed by the two speakers, a registered occupational therapist and a hobbycraft instructor.

8. A nutritionist and a dietitian concentrated their efforts on "Nutrition and Menu Planning." They emphasized the importance of good nutrition for the aged and chronically ill, special diets, meal planning, economical food purchasing, and efficient methods in the kitchen.

9. A sanitary engineer discussed "Sanitation" with emphasis on food handling, dish-washing, construction and design of nursing homes, and safe and sanitary practices for employees and patients. He also reviewed the sanitation regulations governing nursing homes and homes for the aged.

10. A psychiatric social worker dealt with "Mental Health and Psychological Needs and Motivations of the Aged." She described the importance of satisfactory relationships between the patient and the employee, and the employee's need for healthy attitudes and feelings toward the patients in his care.

11. "Recreational and Social Opportunities" for patients was presented by a Salvation Army major. He reviewed what homes in other countries are doing and what is being done in this country, and discussed practical recreational and social activities applicable to patients in nursing homes.

12. The final class session, conducted by two State drug inspectors, dealt with "Dispensing of Drugs and Narcotics" by the nursing home owner to his patients, and his legal responsibilities.

Evaluations

At the opening class 30 people from 15 homes registered. Additional registrations throughout the course brought the final total to 44 students from 21 institutions. Three counties outside the immediate five-county area were represented. Four of the students traveled more than 200 miles for each class session. Among the students were 21 administrators and 23 employees, including 2 private duty nurses. They represented a total of 16 nursing homes and 5 homes for the aged.

The 21 administrators averaged 10.7 grades of school completed, the 23 employees slightly less, with 9.65 grades completed. The administrators averaged 9.25 years of experience in nursing home work and the employees, 5.9 years.

Among the 44 persons enrolled were 1 registered nurse and 2 registered practical nurses; 4 others listed their titles as practical nurse.

No record was kept of who paid the registration fees, but we learned that in two instances

On June 1, 1957, the advisory committee reported to the board of directors of the Saginaw Valley Community Health Services that nursing home personnel wanted and needed educational training, and that a course was feasible, practical, and desirable.

Saginaw Valley Community Health Services, Saginaw County Hospital, and the Division of Gerontology, University of Michigan, agreed to establish and jointly sponsor an experimental training program for nursing home administrators and employees.

After outlining the administrative details, the committee presented the program to the Saginaw Association of Approved Nursing Homes. The association formally approved the course and urged its members to take advantage of it.

Planning the Course

The first course was scheduled to begin June 12, 1957, with 12 weekly sessions held from 7-9 p.m. in the auditorium of Saginaw County Hospital. The trainees' needs and their reactions to these sessions would determine whether the original course would be repeated or a more advanced course offered.

Initially, the advisory committee recommended that the course be open to all persons actively employed in nursing homes, homes for the aged, and county infirmary hospitals in the five counties. The area has 42 of these institutions with a combined capacity of more than 800 beds. Enrollment was encouraged rather than restricted at first; if necessary the class would be divided into smaller groups.

Notices announcing the training course were sent to the 32 nursing homes, 7 homes for the aged, and 3 county infirmary hospitals in the 5-county area. While no enrollments were solicited from institutions outside the 5 counties, staff members from other counties who wanted to take the course were accepted.

A nominal registration fee of \$10 per person was charged to defray the instructors' honorariums and other operating expenses. We also felt that the student who pays for a class is more likely to attend in order to get his money's worth. We planned to issue attendance certificates to those who attended 10 of the 12 sessions.

Instructors were drawn from qualified sources

nearby to keep the program identified locally. Many were in professions dealing with patients similar to those in nursing homes. Some came from the Saginaw County Hospital, the Veterans Administration Hospital, and the local Salvation Army unit, which operates a home for the aged and a golden age club. Others, chosen because of their interest and special knowledge in problems of the aged and chronically ill, were from the State health department, Michigan Board of Pharmacy, Saginaw County Health Department, University of Michigan, and Mt. Pleasant State Home and Training School.

Course Aims and Content

The course was aimed at aiding administrators to operate their homes more efficiently and in the manner most satisfactory to themselves, their employees, and the patients. It was designed to acquaint them with current philosophies of care and rehabilitation of the aged and chronically ill. The course sought to make the staffs of the homes aware that patients have many of the desires, motivations, needs, and likes of all people, and that the aged especially treasure an extra bit of special attention.

The committee felt that staff members who adopted these ideas might significantly improve the quality of their services.

The advisory committee decided on the course's content after meetings with area nursing home personnel. The content was arranged to give the nursing home people a refresher course in their everyday tasks, such as house-keeping, bed-care techniques, and keeping records and reports; to assist the employee in using his equipment and facilities to do better, more efficient work; and to help the administrator use his employees most effectively.

These were the 12 sessions in the first course:

1. The introductory class session was entitled "Opportunities for Nursing Homes and County Infirmary Hospitals in the Treatment of the Aged and Chronically Ill." A professor of gerontology outlined the history of the nursing home in the pattern of medical care of the aged in the United States and evaluated the future of the nursing home.

2. "Patient and Personnel Relations" was presented by a registered nurse who is an assist-

department could review Michigan's new rules and regulations for nursing homes and homes for the aged, adopted in July 1957.

Twenty-five persons, 6 administrators and 19 employees representing 8 homes and 6 counties, registered for the second training course. An administrator and 3 employees came from 2 counties outside the 5-county area. Four homes in the 5 counties were represented for the first time, sending 5 administrators and 13 employees; 4 of the homes represented at the first course sent 1 administrator and 6 employees to the second.

Attendance was good at most class sessions, and all of the 25 people registered qualified for the attendance certificate.

Conscious of the earlier trainees' comments, many instructors attempted, with varying results, different techniques of group dynamics to draw the students into discussions. Arranging the trainees' chairs in a semicircle facing the instructor, and having each student introduce himself at the opening session made the classes less formal and more relaxed.

The instructors also attempted more demonstrations with the trainees participating. At the session on physical therapy the trainees, after watching a demonstration on massage and limb manipulation, practiced on a "patient." The instructors in occupational therapy and hobbycraft showed how to make a Christmas corsage and how to weave a potholder; then the students were given materials and encouraged to use their imaginations in making corsages and potholders.

In their evaluation questionnaires the majority of those in the second course commented favorably on the effectiveness of the group discussion and student participation in certain sessions, justifying the inclusion of these practices in the training course.

The advisory committee has met with the Saginaw Association of Approved Nursing Homes a number of times since the second course ended. The nursing home group commended Saginaw Valley Community Health Services for its service to the nursing homes in the area and inquired about future courses. The interest that has continued after the first two courses has justified plans for a third course, containing new subject matter. We

hope it will be part of a continuous series of training sessions for nursing home administrators and employees in the Saginaw Valley.

Planned for these future courses are detailed subject matter on nursing techniques, including bed and tub baths; comfort and safety devices, such as methods of lifting and moving patients in bed and from beds to chairs; the mechanics of taking temperatures, pulse, and respiration; and general care of the patient's skin, mouth, hair, teeth, and feet.

Conclusions

These two training courses have demonstrated that many nursing home administrators and their employees recognize their own need for help and guidance in their profession, and that they are willing to attend and support organized training which seeks to fulfill their needs.

Independent observations by health department officials who inspect and supervise nursing homes in this area, as well as opinions from certain nursing home administrators, indicate that those who have taken one of the training courses appear to have somewhat modified their attitudes and thinking toward their jobs and the patients in their care. This conclusion is evident in the better quality of work they are doing.

During the class sessions, the students' faces reflected new understanding and new enthusiasm for their jobs. Time and time again they asked the instructors for solutions or suggestions on their specific problems, indicating a desire to act positively.

The actual results of these courses cannot be measured. But the sponsors feel that they were a constructive first step toward improving the nursing homes in the area. If the trainees have learned that patients are people who react and respond as do all other human beings, that nursing home staffs have the power to make life pleasant and worthwhile for their patients, then the students, having gained a new outlook, will do their jobs better.

Those who have worked so diligently to make these courses a reality know that such training is not a panacea. However, they believe that education is the best way to improve habits, attitudes, and conditions in the nursing homes.

fees were paid by the board of directors of nursing homes, and 2 employers paid the fees for their employees, 5 employees in one instance, 3 in the other.

Early in the course, when it became evident that the trainees were not accustomed to taking notes and were losing much helpful information, mimeographed, detailed summaries of each instructor's presentation were made available on a trial basis. These proved to be very popular with the students, and the summaries were continued.

At the 11th session, a single-page questionnaire of 11 subjective questions, to be answered anonymously and returned a week later, was given the trainees. This questionnaire was an effort to ascertain what they had expected to get out of the course, what additional topics they believed should have been included, and what topics they would have eliminated. The participants were also asked about such matters as the coffee break and the time and length of the class sessions.

The trainees had had numerous opportunities to express their desires and preferences during class, but they were questioned at the end of the course so that their opinions would cover all the sessions and be useful to the advisory committee in planning future courses.

Seventy-one percent of the questionnaires were returned and provided valuable information concerning the students' reactions.

For example, the instructor who "had no idea of our problems" or who "didn't apply his subject to our situation" was immediately unmasked by the students. The trainees felt that two of the instructors were not well enough acquainted with the specific problems of caring for the aged and chronically ill patient. However, the majority of the students felt that most of the instructors' subject matter was "very practical and worthwhile" and that the suggestions "worked with our patients."

While the students generally approved the choice of subject matter, they felt they needed more detailed instruction in meal planning, techniques of bed care, motivation of the patient in areas of rehabilitation, and means for satisfying the patients' emotional and mental needs. Numerous trainees suggested eliminating physical therapy, because "our patients are

too old" and "we don't have the time to spend doing it." Generally, they also felt that the session on "Drugs and Narcotics" was only of interest to administrators and therefore should be dropped.

Although the instructors tried to draw the students into group discussions, they did not always succeed, possibly because of the instructor's lack of skill, or simply because of the trainees' reluctance to speak out. Yet 55 percent of those who responded to the questionnaire thought that more group discussion was needed and would make the training sessions more meaningful. This suggestion was emphasized by the fact that many students gathered around the instructor to ask questions and express opinions during the coffee break and after class, although they had failed to respond to the instructor's repeated attempts to draw them into group discussion during the session.

Attendance remained unexpectedly high throughout the course, with not more than five persons absent from any one session, despite some very bad driving weather. Of the 44 registrants, 38 qualified for attendance certificates; 5 of the 6 who failed to qualify attended classes in the second course and received attendance certificates.

Second Course

Because of the success of the first course, and the continuing need for this training, a second course, to begin early in October 1957, was initiated.

Representatives of the advisory committee discussed the second course with members of the regional nursing home association. They planned the second course after considering the results of this discussion and evaluating the questionnaires from the first course.

The second course was essentially the same as the first. Less than half of the nursing homes in the five counties were represented at the first course, and we hoped that additional homes as well as other employees from those previously represented would participate.

One major change was replacing "Drugs and Narcotics" with a session on "Rules and Regulations." "Rules and Regulations" was added so that a representative from the State health

Need Cited for Attention To Basic Sciences

Unless orthopsychiatry takes cognizance of the work being done in the basic sciences, it may well be a horse-and-buggy discipline in a world of motor cars, warned Dr. Reginald S. Lourie, president of the American Orthopsychiatric Association, and director, department of psychiatry, Children's Hospital, Washington, D. C.

Lourie stressed the basic work of neurophysiology and neurochemistry as having "profound implications for our patterns of professional work in the future."

Some of the factors that threaten to mire down the horse and buggy, he said, are the advent of new drugs, the future of psychoanalysis in light of the advances in biochemistry, and management of brain-damaged children. The development of tranquilizers, the salvaging of babies, many of whom have brain injuries, and discoveries in cytological life functioning are part of the new, "motorized" age, he said.

The main thing, Lourie urged, is to see that these sciences cooperate in interdisciplinary roles. He suggested five ways in which the orthopsychiatric profession can prepare itself to advance its interdisciplinary status:

- Communication patterns need to be clarified. Nomenclature common to different disciplines has different meanings ("energy" and "activity," for example). Semantic differences can be overcome if modifications can be accepted as natural, useful, and foreseen eventualities. "Freud himself," Lourie commented, "felt that his ways of describing the phenomena he found were modifiable. He changed his concept, for example, of psychologically based drives to one of forces, somatically based, underlying the drives." The days of usefulness of Freud's terminology will be numbered when we can pinpoint the origin of the forces and control them, he said.

- To prevent compartmentalization of knowledge, all members of the orthopsychiatric team should be acquainted with the structure, phys-

iology, and chemistry of the brain. The extent of training would vary with an individual's specialty and need to know.

- Basic scientists should work as part of the orthopsychiatric team, at least for brief periods of time. All would learn from each other and true interdisciplinary research would be effected.

- Contributions by specialists in orthopsychiatric fields should continue at a high level, avoiding a low common denominator and guarding the interdisciplinary functioning.

- New explorations and speculations must be encouraged. Observational abilities should be cultivated to evaluate new directions, choosing those with promise and putting aside those that appear fruitless.

Finds Therapeutic Milieu A Complex of Variables

Dr. Fritz Redl, National Institute of Mental Health, Public Health Service, reviewed the concept of the patient's milieu as a factor in psychotherapy.

Confusion in the early concepts has led many people into the trap of seeking "the" therapeutic milieu, he said. It is not possible to determine whether a milieu is in itself good or bad or truly therapeutic on the basis of our philosophical, ethical, or political convictions, or our "taste buds." Those who adhere to the concept of total milieu therapy also need to remain cognizant of the fact that elements of the milieu are not equally important or constantly relevant in all situations. In some situations, for instance, the "pecking order," which determines the position of power, is operable; in other situations, it is not. "The thing that counts," Redl asserted, "is not only the description of a variable, but the assessment of the potential impact on the treatment process of a given group of patients."

It is naive, he went on to say, to think that the discovery of a needed milieu "would automatically make it easy to produce that style of milieu in a given place."

The adjective "therapeutic" he mentioned as another trap, and listed seven common meanings of therapeutic to be found in scientific writings. Therapeutic might mean, for example, "don't put poison in their soup," a translation of "the demand for absence of crude forms of punishment in a place that calls itself a residential treatment center." It might also mean, "you still have to feed them," the implication of the belief that children must have an activity program even though the plan of therapy is not concerned with play or diet.

"Milieu" is also a difficult word to define, Redl pointed out. He briefly outlined some of the factors that would be clinically relevant to therapeutic goals, choices in techniques, and assets or liabilities in various phases of therapy. Among these factors would be:

1. Social structure, comprising the type of hospital ward; the distribution of adult roles, in order that patients may be clear about who may make what decisions; the pecking order among the patients; and the communication network that enables the patient to know who can be approached to listen to certain problems.

2. "The value system that oozes out of our pores," for patients can "smell" what a staff feels, regardless of what it says.

3. The routines, rituals, and other behavioral regulations that have an impact upon the ability of the individual to maintain self-control.

4. Group relationships with respect to scapegoats, mascots, cliques, role playing, mob psychology, leadership tensions, and other such forces that demand more concern than "the curious stares of an anthropological slumming party."

5. Personality peculiarities that a patient "swings around his body like a wet towel hitting whoever gets in his path, innocent or not." Personality traits are "real things that hit and scratch if you get in their way."

6. The staff's attitudes and feelings that actually have an impact on the clinic situation.

7. The behavioral output by others to which a patient is exposed, and

The Orthopsychiatric Approach to mental health

CONFERENCE REPORT

At the 35th annual meeting of the American Orthopsychiatric Association, held in New York City on March 6-8, 1958, 70-some papers were presented on various problems of human behavior.

The Association, formed in 1924, is primarily concerned with the development of an integrated approach to the understanding and treatment of human beings as physical, mental, and social entities. It seeks to promote "straight-mindedness" (which the term "orthopsychiatry" connotes), essentially in preventive, therapeutic activities. The annual meeting serves as a forum and a unifying force for psychiatrists, clinical psychologists, psychiatric social workers, and allied specialists concerned with emotional and mental illness.

Eleven papers from the meeting, summarized on the following pages, present several facets of the orthopsychiatric activities.

persons reached by questionnaires or by telephone and personal interviews.

Answers revealed that 46 percent had obtained treatment and 54 percent had not. Of those treated, 75 percent obtained treatment from one of the community's resources suggested by Reiss-Davis. The other 25 percent obtained treatment on their own initiative from other resources. Of those who had not obtained treatment, approximately 25 percent each made no further attempt to find help, contacted suggested sources but abandoned all efforts when refused further, did not try these sources but tried others before giving up, and last, tried many sources, those suggested as well as others, but failed to obtain treatment.

"The reason most frequently given for the inability to obtain treatment by those who made further effort," Fowler and Novick commented, "was that the other community resources also could not provide service within a relatively short time."

One important finding, the authors stated, was that almost 45 percent of those who had not obtained treatment felt that the problem was either solved or conditions had improved to the point where professional help was unnecessary. The authors speculated on the reason for this, but observed that their study could not prove, for example, that the mere interest in treatment the parents had shown resulted in some improvement, or that the conditions had changed.

"If further studies could establish that improvement without treatment could be predicted in certain delineated situations or at specific maturational phases, what a boon this would be for all who work with troubled people," they said. Criteria would then exist to permit the selection of those "who must be treated and those who could be kept off waiting lists."

Recognition of parental frustration in these matters led Fowler and Novick to a thoughtful consideration of a clinic's relationship to those who, for the first time, seek help. The authors recommend the following:

"Procedures in clinics for telephone interviewing should be developed so that everyone engaged in this important public relations function will act with sensitivity and thoughtfulness when talking to a troubled parent who may be faced with a discouraging number of rejections from other community facilities.

"It is important to realize that a parent's application to a clinic may be his first step toward achieving a better adjustment, whether treatment does or does not ensue. If an agency mishandles this first contact, the parent may become immobilized or even regressed, thereby impairing his ability to deal with his problem. If, on the other hand, every member of the clinic staff is aware of the therapeutic value of every contact, then these contacts can be made constructive experiences for the parent, mobilizing his strength to obtain treatment or to handle his situation better.

"Some parents cannot afford to take time off from work to accept treatment offered during regular hours. Clinics should consider the feasibility of adding Saturday or evening hours for marginal income families whose financial stability would be jeopardized if the parent must have weekly sessions during the working day."

Treatment Not Significant In Child Adjustment

An evaluative followup study, conducted by Dr. Eugene E. Levitt, Indiana University Medical Center, and Dr. Helen R. Beiser and Dr. Raymond E. Robertson, Illinois Institute for Juvenile Research, revealed no significant differences in adjustment between psychotherapeutically treated and untreated child patients.

The purpose of the study was to evaluate the effect of psychotherapy at the Institute for Juvenile Research, an agency of the Illinois State Department of Welfare.

For their study, adjustment was defined on the basis of 26 variables; followup meant 5 to 6 years on the

average after the case was closed; and a treated case was one in which at least one member of a family had a minimum of ten 1-hour therapeutic interviews.

Four methods of obtaining a control group were examined and rejected by the authors:

1. Use of patients discharged from State hospitals, because persons in hospitals are usually more disturbed than those in clinic or outpatient groups, and the criteria for discharge are not well defined.

2. Correlational analyses based on certain hypotheses, such as improvement as a function of the number of treatment interviews instead of an actual control group, because results may be equivocal.

3. Use of cases diagnostically eliminated from treatment, because the groups would differ importantly with regard to prognosis.

4. Use of alternate cases in the same group for treatment and control, because the clinic cannot ask the control group to wait too long for treatment. Some will seek therapy elsewhere, and evaluation could only be made at close of treatment and not at followup.

A fifth procedure, and the one accepted for this study, is to use "defectors" for the control group. Defectors are persons accepted for treatment but who fail to undergo treatment.

A sample of 1,006 cases was randomly selected from among treated (experimental) and untreated (control) cases. A total of 327 experimental and 142 control cases actually participated in the first stages of the study. The experimental group number was further reduced to 192 cases, when the qualification of at least ten 1-hour treatment interviews was introduced as a factor in selection.

A study of the experimental and control groups revealed no significant differences in adjustment between the two groups, the authors stated, but mentioned a few conditions upon which this estimate was based.

First of all, the conditions under which the study was made refer specifically to those prevalent at the Illinois Institute for Juvenile Re-

which is distinct from the underlying feelings out of which people act.

8. Activities patients are requested to perform and the performance required of them ("constituent performances").

9. Space, equipment, time, and props: the space the patients work in, the time permitted for various activities, the medical and other equipment, and other "properties" of a clinical setup.

10. "The seepage from the world outside": the impact of visitors, the "sociological body odor" of the old neighborhood the patient may see in being transported from one place to another, excursions, movies, television shows, all the things that impinge upon and break open the institutional setting.

11. The "traffic" regulations of social interactions that normal life leaves to a person's own resources, and the "umpiring" services that may or may not be provided to protect a patient from specific experiences or to interpret certain experiences for him.

12. The "thermostat" for regulating the behavior of patients according to their needs during different phases of treatment. (Behavioral ceilings must be lowered when impulse-panic looms and raised when self-imposed internal pressures mount.)

In the face of so many complex variables, Redl proposed that the clinician isolate ingredients in the milieu as they affect patients in a specific setting during a specific activity. If the clinician knows the actual experience that a concrete situation has produced in a patient as well as what the patient did with the experience, then "milieu" will make more sense, Redl said.

Drift Theory Inadequate, Investigation Reveals

Investigation of the hypothesis that schizophrenics tend to drift into socioeconomically lower sections of a city was reported by Dr. Robert Plank of the Veterans Administration in Cleveland, Ohio.

Four major hypotheses have been offered in the past to explain why schizophrenics are consistently admitted into hospitals in larger numbers from socioeconomically low central districts:

- Statistical artifacts may have clouded the true proportion.

- In certain neighborhoods, schizophrenics are more likely to get into difficulties and therefore to be noticed. This is called the visibility hypothesis.

- The drift hypothesis.

- The breeder hypothesis, which assumes that the type of neighborhood is causally related to schizophrenia, so that by living in certain neighborhoods some people are more apt to develop schizophrenia.

Plank observed that the last two hypotheses are now receiving the most attention.

For his study, Plank selected active cases of schizophrenia at a Veterans Administration mental hygiene clinic. They were white, male, and veterans of World War II. The reasons he gave for selecting this group were: (a) whites have more freedom of residential mobility than nonwhites; (b) men have different residential patterns from women and also there were fewer women; and (c) veterans of World War II provide men of similar ages for experimental and control groups.

The number of veterans in both groups was 32, for a total of 64 in the study. Their present place of residence was compared with their residence at the time of induction into military service. Plank concluded that there was no evidence that these schizophrenics had tended to drift into lower neighborhoods. "but it is shown that they tend to stand still on the residential level on which they are while other people move upward."

The effect of marriage status was next examined, and Plank found that those who were single at induction but were now married had tended to move upward. For the others, there was a balanced upward and downward movement.

When living arrangements were compared, results were similar to those on marital status. Men living

with parents or someone in place of parents at the time of induction, but were no longer, showed an upward tendency. The others were about balanced.

"In considering these figures in conjunction with individual case histories," Plank stated, "we find several patterns clearly emerging. The prevailing pattern is marked by two concerted steps in young adulthood: marriage and emancipation from parental figures. This involves a change in living arrangements which in our culture often opens the way to a residential upward movement. The typical schizophrenic patterns are characterized by the absence of these elements. . . . The new element that recent ecologic research has introduced is that we now have evidence that these patterns account for the relative drift."

We have to consider, Plank concluded, that while studies such as these help us understand the rationale of the drift hypothesis, a similar job is also being done for the breeder hypothesis. Understanding and, eventually, better control of schizophrenia through ecology would be forthcoming "if we were in a better position to see the dynamics by which a type of neighborhood can foster the development of schizophrenia in individuals who live there," he said.

Recovery Ratio Is High For Untreated Applicants

What do families do when they apply to a child guidance clinic for help but cannot be accepted? This question was posed by Sylvia Fowler, chief psychiatric social worker, Reiss-Davis Clinic for Child Guidance, Los Angeles, Calif., and Mary B. Novick, lecturer, School of Social Welfare, University of California, Los Angeles.

At the Reiss-Davis Clinic, where this study was conducted, less than a third of the applicants for treatment could be accommodated. In a 6-month period, 383 applicants were referred elsewhere. Of these, 145 were selected for followup, with 107

more personal desires: they wished to travel, live in a new home, and so on.

The religious persons had more personal fear of death than the non-religious. They expressed concern with purgatory or hell and with their failure to expiate sins, in contrast with the nonreligious who more frequently wished to continue their work in life, provide for their families, finish undertakings, or enjoy their experiences. Even those religious ones who expected to go to heaven were not all free from the fear of death.

Feifel suggested that the fear of death could well be one of the reasons connected with society's rejection of the aged. He also felt that it would be interesting to examine the attitudes toward death of those working in the "life saving" professions.

To deny or ignore death, Feifel said, is to distort life's pattern. Human maturity, he said, entails a recognition of limit. "We are not altogether free in any deed as long as we are commanded by an inescapable will to live. . . . Not until man overcame the fear of death could he permit himself to be bitten voluntarily by a [yellow fever] mosquito, sail to the seven seas, or master the art of flying."

Feifel found that dying patients wished to talk about their feelings and thoughts about death but felt that they were denied the opportunity by those who look after them.

He said a large number of terminal patients prefer honest and plain talk about the seriousness of their illness. "They have a sense of being understood and helped . . . when they can talk about their feelings concerning death. There is truth in the idea that the unknown can be feared more than the most dreaded reality. . . . Patients can accept and integrate information that they are to die in the near future but want a gradual leading-up to this rather than a 'cold shower' technique, as one patient put it."

Feifel said the reaction of the patient to such information depends on his character more than on the event itself. He adds, "The crisis is often not the fact of oncoming death

per se . . . but rather the waste of limited years, the unassayed tasks, the locked opportunities, the talents withering in disuse, the avoidable evils which have been done. The tragedy which is underlined is that man dies prematurely and without dignity, that death has not become really 'his own.'"

Consistent Help Needed For Problem Families

Chronic problem families functioning at primitive and regressed levels can be helped if social agency workers maintain consistent relationships with the family over a long period of time rather than at sporadic intervals. Moreover, services provided for the family must be flexible to meet its needs and must be immediately available. Initial emphasis must be on material support.

These were the conclusions presented by Dr. Joan J. Zilbach of the Judge Baker Guidance Center and United Community Services in Boston, Mass., Lester G. Houston, Greater Boston Council for Youth, and Emily C. Faucett, Smith College School for Social Work, reporting on their study of selected families in Roxbury, Boston.

Seven public and private social agencies pooled their resources "to develop more effective methods for reaching and serving chronic problem families," the authors stated.

Criteria for inclusion in the study were: (a) repeated contacts with social or law enforcement agencies over a minimum of 3 years, with requests for assistance; (b) at least one child in the family under 13 years old; and (c) at least one child in the family who had experienced social difficulties.

Eighteen families were selected for study. These families live in urban areas with high rates of social disorganization and delinquency. All had had at least 15 years contact with 10 or more agencies. With so many agencies trying to help them, duplication and ineffectiveness of services and lack of coordination between the agencies were discovered by the researchers.

Children in these families presented numerous problems, running the gamut from physical handicaps to sexual delinquency. Many had been in courts and State institutions of correction. Surprisingly, the authors commented, "only one family had been known to a child guidance clinic."

In many of the families, fathers were elusive or nonexistent. Fathers and mothers came from homes marked by physical handicaps, psychosis, alcoholism, illegitimacy, prostitution, or imprisonment of one or both of the parents.

According to the type of relationship the mothers had with their families and other persons in the community, the families fell into two broad classifications. Mothers in the first group showed strong attachments to their children, often having many. And they resented any efforts of the social worker except the offering of material assistance. Mothers in this group, however, were able to request medical care for their children even when they were unable to do this for themselves.

Mothers in the second group were characterized by apathy and impersonal relations with those around them. Whereas mothers in the first group exacted from their children fulfillment for the deprivations they had suffered themselves in childhood, maintaining ties with their children when they moved away, those in the second group neglected and ignored their children.

These emotionally deprived people, it was observed, "have learned to function in a fragmented way without the ability to move forward from a primitive level." Their needs are difficult to understand, and agencies that merely supply their requests for concrete assistance do not help them towards individuation, independence, and self-support, the authors pointed out.

Social workers must involve themselves in the routine and repetitious crises of chronic problem families, however difficult such a relationship may be—and chronic problem families are "notable for their ability to rout and defeat the hardest worker." By meeting emotional as well as

search. Second, almost half of the individuals treated were in the hands of relatively inexperienced personnel (students or those with less than 1 year of experience). Third, 34 percent of the patients were treated by more than one therapist, and 90 percent had been seen only once a week.

The authors concluded that the results of the study are due in some part to less than optimal conditions of therapy. "However," they added, "the data themselves do not bear directly on this hypothesis."

Behavior a Function Of Person and Setting

Contributions to mental health and psychological therapy would be more significant if the psychological aspects of environmental factors were classified and quantified along with the "internal" variables of personality, suggested Dr. Harold Raush, Child Research Branch, National Institute of Mental Health, Public Health Service.

Although the investigator is faced with difficulty in defining situations, it can be shown that the particular setting affects the kind of behavior that one sees, Raush said. He indicated that such considerations have implications for problems of diagnosis and psychotherapy. One simple illustration, Raush observed, was that two members of a staff might disagree about the improvement of a patient depending upon where they observed his behavior.

"People exist, behave, fantasy, and think in specific environments, and conversely, for psychology at least, situations exist only in the sense that they impinge on specific organisms," he said. We can predict something about behavior when we know the person involved, and we can predict something about behavior when we know the kind of situation, but, he added, there remains the issue of interconnections between persons and situations. Persons and situations do not work additively in their contribution to behavior, Raush noted. Thus, the ability to gauge the direction of behavior is enhanced far be-

yond an additive function when one's focus is on the interaction between person and situation.

Raush raised the point that two patients could react to the same psychological features of a situation in different ways or "scan the same situation for different features." This obviously implies that variables of personality cannot be played down while one is considering the variables of a situation. "It is at the juncture of these two classes of variables that we meet behavior," he concluded, "and it is the study of this juncture that I should like to emphasize."

Public Health Nurses Promote Mental Health

Public health nurses are a potent resource in the promotion of mental health, commented Dr. Hildegard E. Peplau, associate professor of nursing and director of the program in advanced psychiatric nursing at the Newark College of Nursing of Rutgers University.

Informing the lay public and obtaining its moral and financial support are activities in which the public health nurse has proved herself particularly able, Peplau said. The capabilities of the public health nurse along these lines, she added, are in direct proportion to the confidence and respect she has won through her constant endeavors in the public's interest.

Of particular importance to the promotion of mental health, she said, is the public health nurse's skill and understanding. In times of family crises as well as at those times when a sustained, sympathetic relationship is called for, the public health nurse is prepared to provide support, information, and counsel for the anxious people she may serve.

The public health nurse is also in a strategic position to offset the consequences or to prevent the occurrence of mental illness.

Peplau pointed out that case finding, prompt referral for early treatment, and therapy are routine activities for the nurse and can be easily extended into the field of men-

tal health. In addition, the nurse can bring to the attention of those in need new treatment facilities. She can inform families about the nature and extent of illness in a member of the family, and prepare them for responsible attitudes toward such members when they are returned from hospital care. Lastly, mental health education can be inculcated without difficulty into the public health nurse's normal activities, Peplau said.

Dying Patients Prefer Talking About Death

Two dominant attitudes toward death were discussed by Dr. Herman Feifel of the Veterans Administration Mental Hygiene Clinic, Los Angeles, Calif. One views death in a philosophic vein as the natural end process of life. The other, the religious perception, is that death is really the beginning of a new life and a termination only of physical existence. From these attitudes two contrasting ethics may be derived: a stoic acceptance, or an idealistic glorification of death (or the "after-life") that gives meaning to the biological cycle.

Feifel offered an interim report of the results of questions about death he asked 85 mental patients with a mean age of 36; 40 aged persons with a mean age of 67; 50 young people, mean age 26; and 35 professionals, mean age 40.

Patients were asked what disease they expected to die from. The majority were unable to associate their prospect of death with a specific disease, but a high proportion of mental patients visualized themselves as dying in a violent accident. Most patients hoped to die quickly and with little suffering.

In response to the question, "If you could do only one more thing before dying, what would you choose?" the mental patients voiced religious or social interests. "Give my belongings to charity . . . stop war if possible . . . know more of God," they said. The young persons and professionals, in contrast, expressed

Data Gathering

by Long Distance Telephone

HILARY G. FRY, Ph.D., and SYLVIA McNAIR

A RESEARCH technique relieving many of the headaches in ordinary data gathering was developed during a recent study by the Hospital Research and Educational Trust. Questionnaires were mailed to a widely scattered group of people who were then interviewed by long-distance telephone. The method proved efficient and effective, and at the same time relatively inexpensive.

The research undertaken was an administrative study of hospital planning and license laws, and the field to be covered was both broad and deep. We were concerned with the administration of the following separate but related State programs in 52 States and Territories: hospital survey and construction (Hill-Burton), hospital licensing, and nursing home licensing. While

Dr. Fry was project director, and Mrs. McNair, research assistant, with the Hospital Research and Educational Trust in Chicago. The article is based on the experience of the authors on project W-42, Operation of Hospital Planning and License Laws, which was supported by a research grant from the Division of Hospital and Medical Facilities, Public Health Service.

in some States the three programs were integrated under a single administration, the problems were nonetheless distinct from one program to another. Variation from State to State existed in every phase of the operations—in the legal structure, in the organization, and even in the philosophy underlying the programs. Our objective was to analyze the programs all the way from the enabling legislation to the question of “where do we go from here”; to describe existing conditions and to make recommendations for the future.

As a first step toward acquainting ourselves with the existing programs, our staff members visited seven States in the summer and fall of 1956. We talked with two groups—State officials concerned with the administration of the programs and nongovernmental persons representative of those affected by the programs. Interviews were based on 6 questionnaires containing up to 125 questions. These questions covered the following:

- The law.
- The regulations written under the law, making it more specific.
- The philosophy of the agency: whether its

material needs, "work with families has become not only more understandable but more fruitful," they observed.

Antisocial Behavior in Boys Traced to Their Mothers

In a study of 20 aggressive, antagonistic, and antisocial boys without fathers, the relationship between mother and son was revealed to be intense, highly sexualized, and full of hostility and guilt.

Reporting on this study were Dr. Howard L. Wylie, assistant director, and Dr. Rafael A. Delgado, psychiatrist, of the Worcester Youth Guidance Center in Massachusetts.

The mothers came to the center under external pressure, usually from school authorities, with the chief complaint that their sons could not be controlled or disciplined. The mothers, it turned out, treated their sons in much the same way they had treated their husbands, and, in most cases, that relationship had been a stormy one, Wylie and Delgado said.

The particular forms of behavior the mothers imposed upon their sons were seductive and punitive, the authors said. In many instances, mothers shared their beds with their sons, bathed them at an age when the boys were quite capable of bathing themselves, wrestled with them, and engaged in other sexually charged, symbolic activities.

Punitive measures, apparently arising from hatred for the former mate, self-derogation, or guilt over the sexual substitution of son for father, were inflicted by many mothers on their sons. "We often have the feeling," the authors said, "that the mothers were driven by an intense need to see their sons behind bars." For some mothers, this seemed to be a protective measure: they feared hereditary incompetence and a consequent emulation of the

scorned father by the son. For other mothers, an imprisoned son would be means to a symbolic revenge upon the father.

The boys, reacting to this love-hatred complex, took their revenge through a variety of antisocial activities. Aggressiveness and belligerence were accompanied by enuresis and soiling, and, occasionally, delinquent acts. Several had appeared in courts and three were in corrective institutions, the authors found.

The mothers could not all be delineated in precisely the same terms. Some had found replacements for their husbands and, on the one hand, were adjusting to their situation better, and, on the other, were replacing their sons with psychologically more valid objects for their love. Other mothers were persistent in their substitution of son for father, and still others were "dominated by a vengeful, competitive attitude toward males, and by a strong wish to be a man. These women looked upon their sons as the fulfillment of this wish," the authors averred.

Therapeutically, the situation was not enviable, and the authors said that their attempts to help these people had not been very successful. Most of the mothers rejected the offer of treatment outright or withdrew after a few visits. Most of those who came showed a blatant resistance to treatment. The boys were also seen for only brief periods of time. Those that showed some improvement rapidly relapsed into their former behavior when they returned to their unchanged environment.

Recognizing that the significance of their findings is open to some question, the authors described several limitations that restrict their conclusions and require further investigation: (a) some boys with fathers behave similarly to these boys; (b) not all boys without fathers behave this way; (c) siblings of these antisocial boys may or

may not conform to the same behavioral patterns in the same circumstances; and (d) the socially antagonistic behavior of the child, so far as it is an extension of the mother's maladjustment, may be transitory if the mother is capable of forming a valid relationship with another man and is in the process of doing so.

Atomic Radiation Poses Mental Health Hazards

Atomic radiation "is surrounded with an aura of mystery and must be expected to evoke strong emotional reactions," according to Dr. Frank Fremont-Smith, member of the executive board of the World Federation for Mental Health.

Citing an atomic radiation incident in Windscale, England, another in Holland, and a third in Houston, Tex., Fremont-Smith pointed out that each gave rise to anxieties and fears disproportionate to what the factual situation called for. The problem, he said, was primarily a failure in proper communication, both in official and public domains, so that there was a loss of confidence in the responsible authorities.

He referred to present anxieties about X-rays as an analogous situation. With a great deal of publicity directed toward the dangers of X-rays and faulty equipment, a number of people have refused to permit roentgenograms to be taken, even when urgently required for proper diagnosis.

"The mental health problems of the peaceful use of atomic energy are the mental health problems of preventing war," he concluded, "and with the advent of nuclear weapons the problem of preventing war has become the human problem of human survival. The real issue is not the peaceful use of atomic power but the peaceful use of human power."

also possible to talk and listen without picking up the receiver. Thus, the interviewer's hands were free for taking notes and handling papers. This device was especially advantageous to us. Many respondents were familiar with more than one of the State programs and made comments pertinent to the work of more than one of our specialists. With the hands-free set, more than one specialist could listen in on the interview.

- Supplying the telephone company with a weekly list of names and addresses of the individuals scheduled for calls, an arrangement called "sequence calling."

The next task was to prepare six separate questionnaires: one each for the Hill-Burton, hospital licensing, and nursing home licensing programs to be answered by government agency people, and another set for nongovernmental people. In an effort to devise questionnaires which would be practical in long-distance calls, we edited, shortened, and combined questions from the detailed surveys made during our visits to the seven States. The final drafts contained from 15 to 24 items each. Every effort was made to write as lucidly and specifically as if the questions were to be answered by mail.

These questions were designed to obtain information on the law, regulations, and philosophy of the program, and on the organization, staffing, and operational procedures of the agency. The basic purpose of the survey was to help us identify the persistent problems in the operation of these programs, for it was on these problems that we planned to concentrate our attention. Hence there were virtually no strictly informational questions included in these questionnaires—no "nose count" on "how many States follow what practice."

The questions, particularly those for the nongovernmental people, were principally opinion-type. These we regarded as basic questions: Did they think the Hill-Burton planning in their State had been well tailored to the needs of the State? What services did they think the State Hill-Burton agency should perform for Hill-Burton hospitals? For other hospitals? How thorough were the inspections of hospitals and nursing homes in the State? Were they thorough enough to insure compliance with minimum standards?

In addition, we included a group of multiple-choice questions on both the present and the ideal program. Such questions covered the role of the advisory council, status of the educational program in the State, techniques for putting the State's Hill-Burton plan into effect, how much "toughness" should be used by the State agency in enforcing minimum operational standards, and others. These questions would tell us not only how much agreement there was on present practices, but whether the governmental and nongovernmental people could conscientiously work toward the same goals.

Before selecting nongovernmental persons to be interviewed, we consulted many State hospital and nursing home associations as to which people in their respective States were most familiar with the programs. The list included representatives of medical, hospital, religious, nursing, and nursing home associations, and, in a few instances, of allied fields such as dentistry and architecture. A high percentage were serving or had at one time served on an advisory council to a State program.

Mimeographed copies of the questionnaires were mailed to these individuals with covering letters explaining our plans and informing the recipients that we expected to telephone during a specified week. The mailing was staggered so that the letters arrived about a week before the call was made. This gave the individuals time to think about the questions and make some preparation for answering, but not time enough to file them away and forget them.

In making up the weekly list for the telephone company, calls were scheduled according to normal working hours in the various time zones. The number of calls planned per day was kept low enough to allow for adequate discussion time and for "writing-up" time following the call.

As each call went through, the operator asked the following type of question. "Are you ready to talk with Mr. Fry of the American Hospital Association about the questionnaire?" If the respondent said "No," she would then try to set up a specified time for the interview. There was no charge for this service.

The respondent followed his own copy of the questionnaire while the interviewer noted the

approach is educational or purely regulatory, or combination of the two.

- The organization and staffing of the agency.
- The operational procedures used in the program.

The information from these visits was invaluable. But their greatest value, perhaps, lay in what they proved we could not do. We found that it would be impossible to draw justifiable conclusions from a sampling of a few "typical" States because of the variations from State to State. There are no typical States. Ideally, we should interview individuals from every State before attempting to prescribe for future action.

Conventional Survey Techniques

The ideal method of gathering the type of information we sought would have been face-to-face interviews with large numbers of persons. Unfortunately, we faced a shortage of the two elements essential for this method: time and money. It is not necessary to belabor these points; most researchers will readily recognize that it would be impossible for a staff of four to visit within a few months several hundred people scattered in various towns and cities in every State. If we could have divided the country into four areas with one staff member covering each, our purpose would not have been accomplished, since our staff members had different specialties and each of them had to interview people in every State. Also, the cost could have been prohibitive on our limited budget. There are, moreover, the inevitable delays caused by difficulties in transportation, missed appointments, and other unpredictable obstacles.

If sampling would not suffice, and face-to-face interviews on a nationwide basis were impossible, would a direct-mail questionnaire produce the desired results? The direct-mail questionnaire is the least expensive and often most efficient method of conducting a survey. The disadvantages, however, are well documented in research literature. Misinterpretation of the questions often leads to inaccurate replies. In addition, written comment is sometimes difficult to classify. An interviewer, on the other hand, can often discover patterns in comment

and thereby categorize the replies. About 60 percent response is the maximum expectation from this type of research. It is also far less effective than skillful interviewing for obtaining thoughtful comments in reply to open-end questions.

A questionnaire to solicit information about 52 dissimilar State and Territorial administrations would have to be both general and minutely detailed. Consequently, it would be so lengthy as to be enthusiastically ignored by most respondents.

Since our survey had to include questions requiring thoughtful comment as well as the "yes-no" and "how many" type of question, direct mail would have been a highly inadequate method of obtaining results.

But even more important was the fact that only a limited number of individuals in each State were sufficiently familiar with the programs to give us the information sought. Almost 100 percent response from every State was necessary for our survey to be comprehensive.

Thus an alternative method had to be devised—one that would cover the ground more adequately than either the sampling method or the direct-mail questionnaire, and at the same time cost less in time and money than face-to-face interviews on a nationwide basis.

Long-Distance Telephone Survey

The long-distance telephone call seemed to be the compromise we needed—a means of communication only slightly less direct than face-to-face interviewing and far less expensive. Actually, on analysis of survey results, we found the technique had many positive advantages of its own, but at the start we regarded it as a compromise.

We consulted the telephone company concerning arrangements for the undertaking and were given the following suggestions:

- Installation of special long-distance wires in order to avoid overloading the office switchboard. (There was a slight charge for these lines, but they more than proved their worth in time saved.)

- Use of a special "hands-free" set, consisting of a loud speaker and a microphone. A conventional receiver could be used, but it was

the method, together with cost comparisons. This is particularly true if the individuals to be interviewed have a stake in the project and feel that they have a right to an opinion regarding expenditure.

In our case, however, the telephone technique was heartily endorsed by our respondents almost unanimously. The interview required less of their time than a personal visit, yet the lengthy long-distance call emphasized the value of their opinions to the study. There was some comment to the effect that respondents' own interest in the subject had been intensified by the conversation, and that they welcomed the opportunity to evaluate and review the programs.

Conditions for Use

The technique obviously has its own positive values which under certain conditions make it preferable to any other. It may well be the method of choice for other studies under the following circumstances:

- A budget large enough to permit more exhaustive research than would be possible through a direct-mail questionnaire.

- Neither time nor money sufficient to permit visiting each respondent personally.

- Widely scattered geographic distribution of the persons to be interviewed.

- Great variation and complexity of questions, making written replies inadequate.

- The impossibility of making valid conclusions without an extremely high percentage of responses.

The long-distance telephone survey is suggested to supplement, not to supplant, other methods of gathering data. Many research projects will still be forced to rely on the mails as the most economical method. Others will require a rapport obtainable only by personal visit; "depth interviews," so popular at present, can hardly be held over the telephone. It is still impossible, and will be until telephones include built-in television, to pick up the shades of meaning implicit in the twinkle of an eye or the shrug of the shoulders unless you are facing your respondent.

But if your budget is sufficient, your time limited, your scope large, and your questions complex, it would be well for you to consider using the telephone as a research tool.

Days of Limited Activity Due to Disability

The total number of days which the American people stayed home from work, stayed in bed, or otherwise restricted their activities because of illness or injury has been estimated at 662,800,000 for July through September 1957, in a report issued by the U. S. National Health Survey of the Public Health Service. The report, which is the fourth in a series based on household interviewing, projects the rate of that quarter for the entire year to give an average of 16 days per person.

As of August 1957, the report estimates that about 17 million persons, or 10 percent of the population, had chronic conditions limiting their activities. Women and girls averaged 17.5 days of limited activity per year, compared with 14.1 for males. Children under 5 years of age averaged 6.4 days a year of restricted activity, while people 65 years and over averaged 44.4 days. The average time lost from work was estimated at 7.9 days for each employed person.

answers and comments on a duplicate copy. When answers seemed unclear, when it seemed that the respondent did not quite understand the question, or when the question asked did not fit the situation in that State, time was taken for thorough discussion. In some cases this resulted in a change of answer. For example, a few of the questions involved multiple choices representing varying degrees of opinion. After some discussion the respondent might decide that choice "c" was a closer approximation of his true opinion than his original choice of "b."

As each interview ended, the interviewer took time to write up or dictate his notes. These notes were then typed into the questionnaire itself, on pages facing the actual questions. Thus, we obtained a detailed record of the opinions expressed. However, no record was kept in any case where the respondent requested that he not be quoted.

We considered recording the conversations, but decided against it because of the time required to play them back completely, the distracting "beep" that punctures recorded conversation, and the inhibitions that would have precluded frankness from many people.

Using 2 "hands-free" sets in separate offices and sitting in on one another's calls as necessary, our 3 interviewers talked with 281 persons in 48 States and the District of Columbia, gathering responses to 567 questionnaires, in approximately 8 weeks. About 2 percent could not be located or declined to be interviewed.

The total cost of the calls to all the States came to \$4,703.17—just under \$100 per State, or about \$17 per individual interviewed. Of the total amount, \$17.05 was the charge for installation, \$133.76 the basic cost of the 2 special lines and the 2 speaker phones, and \$4,552.36 the charges for the calls including taxes.

Advantages

For this type of research, the advantages of the telephone technique over a direct-mail questionnaire are the same as those gained through the face-to-face interview: the almost total response, the accuracy and depth of the response, and the clarification which facilitates classification. In addition, the telephone interview overcomes one disadvantage of the face-to-face

interview: the great expenditure of time and money.

We estimated that for the total of \$4,703.17, in the 8 weeks spent in telephoning, we would have been able to visit in person only 10 western States, or about 80 individual respondents. (And this figure does not include the considerably greater payroll expenditure which the longer time span would have entailed.) The cost per person in this event would have been \$80, as compared with the \$17 actually spent.

Other more subtle advantages of this technique became apparent as we proceeded.

The telephone interviews were far more concentrated and free from both interruption and digression than the usual personal interview, since the awareness of the cost of long-distance telephoning exerted some pressure in this direction on both interviewer and respondent. (In no instance was the conversation interrupted by a phone call!)

Respondents had, for the most part, made more preparation in advance for answering the questions by telephone than is usually made in anticipation of a personal visit. In a number of cases respondents had even held conferences with other staff members or colleagues concerning the questionnaires.

The time between the first and last calls of the survey was less than probably would have elapsed from beginning to end of a direct-mail survey. (We used direct-mail questionnaires on some other phases of our study, and replies dribbled in for months.) The concentration of study on the part of the researchers into a shorter span of time contributes to more uniform evaluation of data, since it lessens the tendency to shift emphasis during the progress of the study.

Respondents' Reaction

The idea of indulging in such long telephone conversations for research purposes is unusual enough to be startling to the persons called. There was, in fact, some slight criticism of the generous outlay of funds in this manner. Although it was easily answered, the researcher who intends to employ this technique would be well advised to avoid such criticism by offering in advance a straightforward explanation of

In Routine Use

Stabilized antigen emulsion is now used at the Venereal Disease Research Laboratory in the routine performance of the VDRL slide, tube, and spinal fluid tests. A volume of antigen emulsion sufficient for approximately 1 week's testing is prepared and stored in the refrigerator at 6°–10° C. An aliquot sufficient for 1 day's testing is removed from the stock bottle, warmed to room temperature, and then checked with control serums for standard reactivity before use in testing individual serums. A new aliquot from the refrigerator is used each day.

—AD HARRIS, *Director,*
Venereal Disease Research Laboratory.

Four of these vials were stored at 37° C., and one vial was tested each week for 4 weeks. The remaining vials were divided into two groups. One group was stored at room temperature (23°–29° C.); the other was stored in the refrigerator at 6°–10° C. Samples of antigen from each group were tested periodically in comparison with an emulsion of standard reactivity, freshly prepared on the day of testing. A vial of stabilized antigen emulsion was used for at least 1 week if it retained its standard level of reactivity for that period of time. Antigen emulsions stored at 6°–10° C. were allowed to stand at room temperature for at least 30 minutes before use. When testing was completed they were returned to the refrigerator.

Samples of stabilized emulsions also were sent through the mail and, after 3 days in transit, were returned to the laboratory and tested for a period of 7 consecutive days when stored at 6°–10° C.

Results

The keeping qualities of the stabilized antigen emulsions prepared and handled as described are summarized in the table.

The stabilized antigen emulsions were satisfactory for use for 7 consecutive days after storage at 6°–10° C. for periods of 4 to 6 weeks. In one instance, an unopened vial was refrigerated for 4 months and found to be of standard reactivity when tested.

The stabilized antigen emulsions stored continuously at room temperature also retained their standard level of reactivity for relatively long periods, although storage at 23°–29° C. was not as satisfactory as refrigerated storage. Emulsions were satisfactory for use for periods varying between 2 and 4 weeks. Deterioration tended to occur more rapidly as temperatures exceeded these limits.

Emulsions were stored at 37° C. in order to determine the effect of the highest probable temperatures to which they would be exposed during shipment. When stored at this temperature in the incubator, they were found to be of standard reactivity after 2 weeks; however, slight but definite loss in reactivity was noted after 4 weeks' incubation.

The mailed specimens showed no change in reactivity during a period of 7 consecutive days of testing.

Comparative VDRL slide tests were also performed with stabilized and freshly prepared antigen emulsions (duplicates of each) on 570 serums selected at random from specimens submitted to this laboratory for testing. Stabilized emulsions were stored from 1 to 6 weeks at 6°–10° C. before use. Discrepancies in results obtained between the stabilized and freshly prepared antigen emulsions were not more numerous than those obtained with duplicate, freshly prepared antigen emulsions. In all instances, disagreements represented critical, borderline reactions, where the results might have been read either as rough nonreactors or as minimal weak reactors. Stabilized

Effect of storage time and temperature on reactivity of stabilized VDRL emulsions

Storage method	Period of storage (weeks)					
	1	2	3	4	5	6
Refrigerator (6°–10° C.)	SR	SR	SR	SR	SR	SR
Room temperature (23°–29° C.)	SR	SR	SR	SR	LR	---
Incubator (37° C.)	---	SR	---	LR	---	---
Mailed (3 days in transit)	1 SR	---	---	---	---	---

¹ Not tested beyond 7 consecutive days.

SR—standard reactivity; LR—less reactive than standard.

Method of Stabilizing Antigen Emulsion Used In VDRL Syphilis Tests

HILFRED N. BOSSAK, B.S., and
WILLIAM P. DUNCAN, B.S.

ONE of the most important factors contributing to reproducibility of flocculation tests for syphilis is the ability to prepare antigen emulsions of uniform reactivity. Deviation from prescribed methods, use of reagents of poor quality, unclean glassware, and temperature variants may result in antigen emulsions of substandard reactivity.

The most widely used microflocculation tests employing cardiolipin antigen, described in the 1955 Manual of Serologic Tests for Syphilis (1), limit the use of antigen suspensions to the day on which they are prepared, or, as in the Kline standard test, to 48 hours.

A method whereby antigen emulsions of standard reactivity might be preserved for use in these tests would appear to be a valuable aid in promoting uniformity of test performance by eliminating the necessity of preparing them each day tests are performed, thus permitting their storage, shipment, and use over relatively long periods of time.

Antigen emulsions preserved for varying periods of time by the addition of preservatives or by storage at low temperatures have been used in other procedures. Hinton glycerinated indicator (1) can be used for at least 3 weeks when stored in the refrigerator. Chediak (2) added benzoic acid or beef albumin to cholesterolized alcoholic extracts of beef heart used to preserve emulsions in a microflocculation test on whole blood. Kurtz and Hill (3)

extended the use of a Kahn antigen emulsion to 36 hours by centrifugation and resuspension of the sediment in 0.9 percent saline. Modified antigen emulsions used by Rappaport and Eichhorn (4, 5) for several microflocculation tests were satisfactory for use for 2 weeks when stored on ice, and Portnoy and co-workers (6) modified VDRL antigen emulsion by centrifugation and the addition of choline chloride for use in a screening procedure and found that it could be used for 1 week if 0.01 percent merthiolate was added.

Investigative studies were undertaken at the Venereal Disease Research Laboratory to determine whether some of these reagents or procedures could be applied to the stabilization of antigen emulsions for the most widely used microflocculation procedures, such as the VDRL, Kline, and Mazzini tests, without affecting standard test reactivity level.

This report describes a method employing benzoic acid in the preparation of a stable antigen emulsion of standard reactivity for use in the VDRL slide, tube, and spinal fluid tests. Stabilized antigen emulsions prepared in this manner retained their standard level of reactivity during shipment and long storage periods, thus eliminating the necessity of preparing fresh antigen emulsions each day tests were performed.

Materials and Method

A stock 1.0 percent alcoholic solution of benzoic acid was prepared by dissolving 1 gm. of benzoic acid, reagent grade, in 100 ml. of absolute ethyl alcohol. This solution was stored in a glass-stoppered flask at 6°-10° C., and was satisfactory for use indefinitely.

VDRL antigen emulsion was prepared in 10.0 ml. volumes as described in the published method (1). To each 10.0 ml. volume of freshly prepared material, 0.1 ml. of stock 1.0 percent benzoic acid solution was added so that the final concentration of stabilizing substance was 0.01 percent. Each aliquot of this stabilized antigen emulsion was tested with control serums, and all those of standard reactivity were pooled. The pool was dispensed in convenient volumes of 5.0 ml. or 10.0 ml. into screw-capped vials.

The authors are bacteriologists with the Venereal Disease Research Laboratory, Venereal Disease Branch, Communicable Disease Center, Public Health Service, Chamblee, Ga. Technical assistance in this study was provided by Marjorie A. Lantz, a medical technician at the laboratory.

Silicosis, a Continuing Problem

VICTORIA M. TRASKO, A.B.

THE CONTINUANCE of silicosis in the United States reflects the cumulative effect on society of a preventable but still prevalent occupational disease. After more than 35 years of definitive research and almost as many years of application of controls in some measure, hazardous exposures still exist and new cases of silicosis are developing. The major impact of the disease today, however, is manifested as a socioeconomic problem.

To view the present state of the silicosis problem in proper perspective, I should like to mention some of the past developments that have bearing on the situation today.

Early Knowledge of Silicosis

Prior to the 20th century, the only intimation of silicosis in the United States was found occasionally in physicians' reports of lung diseases with a suspected occupational involvement (1). For instance, in 1887 an autopsy report on a stove foundry worker in Poughkeepsie, N. Y., described the cause of death as the condition that we know today as silicosis. Also in that year, a report appeared on 40 workers employed 25 years or more in a cutlery factory. Of the 34 men who had contracted what was referred to as a chronic disease of the air passages, 23 had died within the previous 10 years. A third report, which came out about 1900 in Utah, told of 30 men who had died following 1 to 2 years' exposure to dust from crushing

quartzite ore in a gold assaying mill in Nevada. The description of findings resembled very closely the characteristics of silicosis.

Entering the 20th century, we find a slow, steady awakening of interest in the health problems of dusty trades. The mechanization of certain stone and mining operations and, in particular, the introduction of pneumatic tools which generated substantial amounts of fine dust contributed to the rising incidence of silicosis and its complicating companion disease, tuberculosis. Evidence of excessive mortality from tuberculosis and relationship to dust exposure began to mount, as reflected in the occupational mortality statistics compiled by Dr. F. L. Hoffman of the Prudential Life Insurance Co. in 1907 and 1918 (1).

Concern over the large incidence of tuberculosis in the dusty trades gave rise to the first real investigation of the problem. The study was undertaken in 1913-15 in the lead and zinc mining industry around Joplin, Mo., by the Public Health Service and the Bureau of Mines (2). Of 720 lead and zinc miners examined, 45.7 percent were found to have silicosis and another 14.3 percent, silicosis complicated with tuberculosis.

Between 1920 and 1930, other environmental and clinical investigations of workers in dusty operations followed. Among these, an examination was made in 1920 by local physicians of 427 granite cutters in Barre, Vt. (1). Practically all of the group were found to have silicosis or tuberculosis alone or in combination. During 1924-26, the Public Health Service, in its study of the Vermont granite industry, found that practically all workers exposed to high concentrations of the dust developed the disease and that a large proportion eventually became tuberculous (3).

Miss Trasko is program adviser, Occupational Health Program, Bureau of State Services, Public Health Service, Cincinnati, Ohio. This article is based upon a paper presented at the ninth annual meeting of the McIntyre Research Foundation, Toronto, Canada, January 28, 1958.

emulsions were found to be equally satisfactory for use in the VDRL tube flocculation tests with serums and the VDRL tests with spinal fluid.

The use of benzoic acid as a stabilizing substance therefore did not appear to affect the reactivity level of the antigen emulsion for any of these three tests.

Discussion

During the course of these studies, other preserving substances and factors which might affect the relative stability of antigen suspensions were investigated. The presence of alcohol in these suspensions and its possible effect on their stability were considered, since it has been observed that in some instances emulsions containing no alcohol deteriorate less rapidly than those containing alcohol. Alcohol was removed from VDRL antigen emulsions by dialysis, or by centrifugation at $20,000 \times g$. and resuspension of the sediment in VDRL buffered saline. Both methods, however, resulted in preparations that were less reactive than standard.

The use of proteins as stabilizing substances for colloids and oil-in-water emulsions is well known. Bovine albumin in varying concentrations was added to VDRL emulsions, but in all instances these preparations were undersensitive and showed evidence of contamination after 1 week's storage at 6° – 10° C.

Glycerin, too, is a substance commonly used to stabilize emulsions by decreasing surface tension. In addition, as previously indicated, it is used in the preparation of Hinton glycerinated indicator which can be used for 3 weeks. Addition of glycerin to VDRL emulsions, however, either affected their standard reactivity level, or, when used in low concentration, did not preserve them for any significant period of time.

The use of various salts of the fatty acids, such as the stearates, oleates, and palmitates, was also considered. None of these substances, however, was available as a reagent grade chemical readily soluble in either water or alcohol; they were therefore not used.

Of all the substances tested, benzoic acid proved to be the most satisfactory for stabiliz-

ing VDRL antigen emulsions. It was readily available as a reagent grade chemical, a 1.0 percent stock solution was stored and used for long periods of time without deterioration, and an extremely low concentration (0.01 percent) was effective in preserving the standard reactivity level of the emulsions for long periods of time.

Preliminary studies have also been carried out using benzoic acid as a stabilizing substance for preserving the standard reactivity of antigen suspensions used in the Kline standard and Mazzini microflocculation tests. Results obtained with both these procedures will be reported later.

Summary

A procedure employing benzoic acid as a stabilizing substance for preserving the reactivity level of antigen emulsions for use in the VDRL tests is described.

The reactivity of the stabilized emulsions varied according to the temperature at which they were stored and the length of time they were kept.

Comparative results obtained on 570 serums tested with freshly prepared and with stabilized emulsions in the VDRL slide test indicated that benzoic acid does not affect reactivity, levels.

Of several stabilizing substances tested, benzoic acid was the most satisfactory.

X-rayed periodically who were initially exposed after the installation of dust controls from 1937 to 1939 (8).

The transition to dust control, however, was not as universal or as rapid as some like to believe. During the war years, 1941 to 1945, ventilation equipment was scarce and was released on a priority basis, mainly to war production industries. Studies in Georgia, for example, revealed that as late as 1948 some granite sheds and quarries had silica exposures many times in excess of recommended limits (9).

The job of educating the smaller employers in preventive techniques was far from complete. As late as 1953 a death from acute silicosis, confirmed by histological examination, occurred in one of the States. The worker, 24 years old, had had 5 years of exposure in a small plant making cleansing powder which was 100 percent pure "flour of silica." The 18 dust samples collected by industrial hygiene personnel were all above 16 million particles per cubic foot of air, with counts reaching 770 million particles. The owner had no idea of the hazardous nature of his business and had taken no preventive measures. After official investigation, the plant was closed.

Since the war years, many research advancements have been made which in retrospect have been helpful in shedding more light on the epidemiology of dust diseases. The impression of the late 1930's carried into the 1940's, that the dust problem was largely solved, was on the wane by the 1950's. New uses of silica and its byproducts (10), more widespread mechanization of dusty operations, and technological advances gave rise to the suspicion that possibly new types of exposures were occurring.

The present-day concern with silicosis as a continuing problem led in 1956 to a series of Congressional hearings on safety and health in metal mines (11). This is the second time that Congressional hearings have focused primarily on silicosis as an occupational health hazard.

Prevalence of Silicosis in the United States

Despite all the interest, research, and activity since the 1930's, the precise prevalence of dust diseases remains a mystery. In 1933, Lanza and Vane presented a paper entitled "Prevalence of Silicosis in the General Population and Its Effects Upon the Incidence of Tuberculosis" (12). The status of the disease was disclosed in the first four sentences of the paper. "I wish to make it perfectly clear that there is little in this paper to justify its ambitious title. Silicosis is not a reportable disease. It is still commonly not diagnosed. Even in districts where it prevails, it does not appear on death certificates to the extent which one might expect."

On the basis of various investigations, the authors estimated conservatively that 500,000 workers were then exposed to a harmful degree of silica dust in the United States. Various other estimates, including the projected figures of the Public Health Service (13), established a total silica-exposed population of between 1,500,000 and 2,000,000. Cummings, at the Fourth Saranac Laboratory Symposium on Silicosis in 1939, ventured a guess that about 50,000 employed workers at that time might be found with definite evidence of silicosis (14).

On the assumption that these estimates are valid, the outlook for silicosis as a continuing problem is rather foreboding. Taking the 1933 estimate of 500,000 harmfully exposed workers and applying the then prevalent ratio, of 1 out of every 4 exposed as eventually developing the disease, we arrive at a figure of 125,000 potential silicotics. Even Cummings' guess of 50,000 workers with silicosis in 1939 would impose on today's society a burdensome residue of persons who had acquired silicosis earlier.

In 1955, because of numerous requests for statistics and the mounting reinterest in silicosis, the Occupational Health Program of the Public Health Service began a search for prevalence data in the States. I shall refer only briefly to the results of this study, published in 1956 (15).

By putting together the piecemeal information obtained from official agencies, we arrived at a total of 10,362 cases of silicosis on record in 22 States between 1950 and 1954. They included open and settled compensation cases, cases discovered through X-ray examination of workers in dusty trades, reports by physicians, and some death records. Since then we have added to this total, so that we now have some information on 12,763 cases in 26 States, cover-

A 1928 study by the New York Department of Labor revealed that 57 percent of 208 workers engaged in rock tunneling in New York had silicosis (4). Similar studies and investigations by various groups were carried out in metal grinding, abrasives grinding, porcelain enameling, and in the sandstone and cement industries. In operations where a dust exposure was evident, incidence of silicosis ranged as high as 67 percent. Studies of this type continued into the 1930's, providing ample evidence of the severity of the dust hazard in certain industries and the dire need for dust control measures.

Developments of the 1930's

Despite the steady buildup of incriminating information, not until the 1930's was silicosis generally recognized as a serious occupational health hazard. The awakening was precipitated by a tidal wave of lawsuits in civil courts based both on legitimate and spurious claims of dust disease due to the occupation. Had these claims prevailed, it is alleged, many of the affected industries and insurance companies would have gone bankrupt. In 1933, alone, it was estimated that damage suits of more than \$100 million were outstanding (5). The grounds for lawsuits were negligence of the employers, since at that time only six States, by so interpreting the term "personal injury," could compensate for silicosis under their laws.

Several factors undoubtedly contributed to this wave of lawsuits. For one thing, a sufficient number of years had elapsed to build up a sizable silicotic population. For another, the Nation had been plunged into an economic depression and silicotic workers were seeking some form of financial compensation for their illness. Another probable reason was the impact of the lag in the application of dust control techniques already developed through scientific research. The lawsuits disclosed that the knowledge of these was not widespread. Employers claimed that they had not been fully informed or warned of the special dangers of certain dusts and, therefore, exercised only general care in prevention which they thought was adequate.

Among other widely publicized events of

the 1930's was the Gauley Bridge disaster in West Virginia. Congressional hearings held in 1936 revealed that 476 workers died from silicosis and 1,500 others were suffering from the disease they contracted while digging a rock tunnel for diverting water to a hydroelectric plant during 1932-34 (6). No safeguards of any kind were used to control the exposures to rock dust, which was almost pure silica.

Working and living conditions among lead and zinc miners in the Joplin, Mo., area continued to be publicized by commentators and writers. Among these was Dr. Alice Hamilton with her article *A Mid-American Tragedy* (7), published some 25 years after the first silicosis investigation was made in the Joplin area. In Massachusetts and New York, commissions were appointed to investigate hazardous conditions in foundries, granite sheds, and other dusty industries.

These and other events of the 1930's catapulted silicosis from relative obscurity into widespread notoriety and spurred the taking of long awaited action. For example, nine States passed legislation bringing silicosis under the compensation laws between 1933 and 1939. By 1949, the number of States making some legal provision for compensation of silicosis reached 40. The First Saranac Laboratory Symposium on Silicosis was held in 1934, and the National Conference on Silicosis in 1936.

Only three States, Ohio, New York, and Connecticut, had industrial hygiene programs prior to 1934, but with the help of Social Security funds, 26 State and city governments established industrial hygiene programs from 1936 to 1939. Several insurance companies also instituted activities for the prevention and control of occupational diseases for the employers they insured.

In a less dramatic vein, industry began the task of controlling and eliminating hazardous dust conditions. The high degree of success achieved by these efforts is unquestionable. One instance is exemplified in the recent follow-up study of the Vermont granite industry by the Public Health Service and the Vermont Industrial Hygiene Division. Dust counts were found within recommended limits and no evidence of silicosis was detected among men

Figure 1. Deaths from pneumoconioses in the United States, 1941-55.

of almost 2,000 per year (16). Tuberculosis with mention of occupational disease of the lung accounted for 28 percent of the 11,650 total; silicosis and anthracosilicosis for 60 percent; and unspecified and other pneumoconioses for 12 percent. The 12 percent includes a small number of deaths from asbestosis and anthracosis; however, most are unspecified pneumoconioses and are probably silicosis.

It is not possible to determine to what extent mortality from dust diseases in the United States has increased or decreased over the past years. Figure 1 presents the number of such deaths since 1941. However, prior to 1949, a fixed system of priorities was used in selecting the cause of death to be tabulated. With the sixth revision of the International List of Causes of Death, the cause of death tabulated was, in general, that designated by the certifying physician as the underlying cause of death. This change in coding rules has therefore increased the number of deaths assigned to pneumoconioses since 1949.

The graph suggests, however, that the number of deaths due to tuberculosis with mention of

occupational disease of lungs has been gradually decreasing. The trend for silicosis and anthracosilicosis shows a rise for the first coding period and a level plateau for the second period. It is believed that the calculation of rates, even if the exposed population were known, would not materially affect this picture. If increases in employment in the manufacturing industries and decreases in mining are taken into account, the number of workers in dusty trades probably has not changed appreciably over the 1941-55 period. The steady rate at which the silicotic population is dying off gives us a fairly good idea of the extent of silicosis today and in retrospect.

Deaths from pneumoconioses in Pennsylvania accounted for 40 percent in 1953 and 45 percent in 1954 of all such coded deaths in the United States. For this reason, Pennsylvania death certificates were used to obtain further information. With the aid of the National Office of Vital Statistics, we scanned 137,000 death certificates covering January, February, and March 1953 (a trial period), and the entire year 1954. Information was transcribed on age,

ing from 2 to 6 years of records between 1950 and 1955.

When we began our inquiries, we were aware of the impracticability of developing conclusive evidence. But, by accumulating data on a sufficiently large number of cases, we hoped to come up with some general answers.

We found that, in addition to the present silicotic population being sizable, it is primarily an elderly one. Only 2.5 percent of the cases are under 35 years of age; 21 percent are between 35 and 49 years; and the remaining three-fourths, 50 years and over. Since most of our data are for compensable cases representing primarily a disabled group, this distribution may be biased. Records of workers with nondisabling silicosis are scarce, as the disease is under-reported, and very few States compensate for partial disability from it. When partial disability is compensable the proportion of cases of persons under 50 years of age tends to be higher. In West Virginia, for example, it was 35 percent and in New Jersey 55 percent. In States compensating for total disability only, such as Montana and New York, 4 and 15 percent respectively of the cases involved workers under 50 years of age.

The mining industries, coal, metal, and non-metal mining and quarrying, were associated with two-thirds of the cases. Of the manufacturing industries, foundries were associated with 16 percent, and pottery, stone, silica-brick, tile, clay, and glass industries with the remaining 18 percent.

The age distribution by industry showed in each group some cases among men under 35 years of age. However, none of the case totals for the under 35-year-old group exceeded 5 to 9 percent of the industry's total cases. The 50- to 64-year-old group accounted for most cases within each industry as well as for all industries combined.

Another revealing fact was the number of new cases among workers entering dusty trades for the first time since 1935. Of 3,455 cases in 10 States for whom reasonably adequate employment histories were obtained, 10 percent allegedly received their entire dust exposure after 1935. The distribution of these cases by industry shows every group produced at least a few, but that the mining industries, foundries,

and nonmetallic mineral industries were responsible for over one-half of the recent cases.

Our data on pulmonary tuberculosis as a complication of silicosis are not satisfactory since not all States record or tabulate the condition. This is especially true for compensation cases, despite the fact that tuberculosis accounts for most of the disability. Proportions of silicosis cases with tuberculosis reported in a few States are: 34 percent of 111 litigated cases in California; 30 percent of 637 open and closed compensation cases in Ohio; 62 percent of 507 hospital clinic cases and deaths in Missouri; 53 percent of 318 clinic cases in Oklahoma; 12 percent of 162 workers X-rayed in North Carolina; and 24 percent of 723 workers X-rayed in Vermont.

These data give the impression that pulmonary tuberculosis is not as damaging to health of silicotics as it once was, and even with the complication many silicotics live to old age. For example, men with simple and complicated silicosis had the same average age, 56 years, and length of employment, 32 years, according to X-ray examination records of Vermont granite shed workers living during 1950-55. Workers deceased during the same period were, on the average, 6 years older than those in the living group. The only other difference observed was that the persons in the deceased group who also had tuberculosis had worked an average of 4 years less.

This summarizes the few general facts we were able to glean from records on the nature and extent of silicosis in the United States. The current figure of 12,763 cases reflects the extent of our success in collecting statistics on silicosis rather than serving as a measure of prevalence. As such, it is a gross underestimate, owing to the incompleteness of sources of data and lack of statistics for other States with silica hazards.

Mortality Statistics

Further proof of the inadequacy of our so-called prevalence figure lies in mortality statistics of the National Office of Vital Statistics. About 20 percent of the 12,763 cases on record in 26 States during 1950 to 1955 were known to have died. In the entire United States over the same period, 11,650 deaths were recorded as due to occupational pneumoconioses, or an average

cosis costs for varying periods between 1950 and 1955 ranged from \$2,232,000 to \$12,608,000. In the other 12 States (Arkansas, California, Colorado, Idaho, Illinois, Nevada, New Jersey, North Carolina, Utah, Virginia, Wisconsin, and Washington) the spread was from \$78,116 to \$795,431.

Compensation for silicosis is a slow, costly, and complicated business. Requirements for eligibility, determination of liability, assessment of disability, amounts of awards, and methods of processing cases differ tremendously from State to State. In the group of 18 States, the average cost per case ranged from \$1,390 in West Virginia to \$16,180 in New York. Individual payments were as low as \$380 for temporary disability in New Jersey and \$1,000 for stage 1 silicosis in West Virginia and as high as maximum indemnity awards of \$12,000 in Utah, and more than \$20,000 in States with unlimited benefits such as Ohio. When medical benefits are added, costs of some cases exceed \$30,000 each.

The average cost per case for the 18 States combined is \$4,450. In contrast, the average cost of compensation claims for all work injuries in the United States ranged from a low of \$343 in Alabama to a high of \$1,055 in Montana (17).

Data on compensation costs for earlier years are scarce. Lanza reported that claims for silicosis compensated in 1938 and 1939 average 10 to 12 per year in the industrialized States (14). Up to that time legislation was comparatively new and not widespread. The few States then reporting costs, Wisconsin among them, found that dust diseases accounted for one-third to more than 90 percent of all the occupational disease costs.

The experience of two States, Pennsylvania and Wisconsin, which have published continuous data, shows that costs since 1950 have increased substantially (fig. 2). This is typical of what has probably occurred in many other States. One of the many reasons for the increased claim load is that most of the occupational disease compensation laws were passed after 1940, and since 1950 many have been liberalized.

These figures, impressive as they may be, cover only a fraction of the costs and burdens

Figure 2. Compensation costs in two States.

on today's society of the accrued liability of preventable disease. Countless numbers of true silicotics not legally eligible for compensation are forced to turn elsewhere for help. If restrictions in laws were lifted, the costs would undoubtedly skyrocket to unforeseen proportions.

Conclusions

This, in brief, sums up the evidence we have on silicosis as a continuing problem. The majority of cases on record represent disabled workers and a backlog of early acquired silicosis. The major impact on society is an economic one as reflected in high compensation costs.

The true extent of nondisabling silicosis cannot be determined from official records as yet. There is sufficient evidence, however, to suggest that this group of not yet discovered or disabled silicotics may be important in perpetuating the silicosis problem. There is also evidence of need

occupation, and causes of death for all certificates giving silicosis, anthracosilicosis, or pneumoconiosis as a primary or contributory cause of death.

In this manner, we obtained a population of 1,519 deaths among silicotics for the 15-month period. Pneumoconiosis as a primary cause of death was assigned officially to 60 percent of this 1,519 total; other causes of death were assigned to 40 percent. Thus, 2 out of every 5 deaths among silicotics were attributed to other causes.

Although uncomplicated silicosis is showing up on death certificates with relatively greater frequency, it is still commonly omitted. For instance, in another State where I had access to the compensation files, silicosis was not mentioned on 42 out of 269 death certificates filed with the claims, although the majority of these cases had received disability benefits for many years prior to death.

The causes of death on the 1,519 death certificates were tabulated to determine what other conditions are associated with these deaths. After several futile attempts at multiple-cause coding, the tabulation shown in the table emerged. It is offered for whatever it may be

Frequency of other conditions mentioned on 1,519 death certificates listing silicosis, anthracosilicosis, or pneumoconiosis as a primary or contributory cause of death, January-March 1953, January-December 1954, Pennsylvania

worth; I have made no attempt to interpret it.

An age distribution showed that none of the deceased was under 40 years of age at the date of death; 5 percent were between 40 and 49 years old; 39 percent between 50 and 64 years; and 56 percent over 65 years. There were more deaths under 65 years of age among those who also had tuberculosis, 59 percent, than among the others, 43 percent. In our prevalence study we reported that individuals with silicosis are living a relatively full life span.

By occupation, 76 percent of the 1,519 deceased were miners. Coal mining was specified occasionally, but rarely was it described as anthracite or bituminous. Occupations for the remaining were: foundry or steelwork, 6 percent; stonecutting, quarrying, brickmaking or other work associated with silica exposures, 2 percent; painter, electrician, repairman, truck-driver, watchman, restaurant worker, clerk, farmer, or other occupations not associated with silica exposures, 9 percent; and laborer not otherwise specified, retired, or not known, 7 percent.

Compensation Costs

The most forceful evidence we have of silicosis as a continuing problem is what the disease costs society today. The compensation costs of 9,829 cases on record between 1950 and 1955 in 18 States amounted to \$43,693,000. This amount covers benefits paid on open cases up to 1954 or 1955 and awards allowed or paid in death cases. It covers a 6-year period for 4 States, a 5-year period for 9 States, and between 2 to 4 years for 5 States. Medical costs are not consistently included or reported. Making allowances for incompleteness of information and allowing for costs in other States for which data were not available, compensation costs of silicosis cases outstanding since 1950 can be estimated to be at least 10 million dollars per year. In contrast, the budgets of official industrial hygiene agencies for the entire country amount to less than 3 million dollars annually. These agencies are responsible for the control and prevention not only of silicosis but also all other occupational diseases.

In 6 States (Alabama, Montana, New York, Ohio, Pennsylvania, and West Virginia) sili-

Topical Applications Of Sodium Fluoride And Stannous Fluoride

GEORGE A. NEVITT, D.D.S., M.S.P.H.,
DAVID H. WITTER, D.D.S., M.P.H.,
and WINSTON D. BOWMAN, D.D.S.

SODIUM FLUORIDE applied topically to the teeth gives approximately 40 percent reduction in the incidence of dental caries in children (1-3). Other fluoride compounds may be even more effective. Laboratory studies suggest that stannous fluoride is superior to sodium fluoride in reducing the solubility of powdered dental enamel (4-6) and whole tooth sections in weak organic acids (7), and experimental studies in hamsters (8) and rats (9-11) have corroborated these findings. Also, there are reports of approximately 60 percent reduction in dental caries in children when stannous preparations were used (12-14).

The present study has tested further the effectiveness as dental caries preventives of 2 percent stannous fluoride and 2 percent sodium fluoride. Nearly 600 children 9-14 years old in Milwaukie and Oregon City, Oreg., participated in all phases of the 16-month study. The children were divided into two comparable groups, one group receiving stannous fluoride and the other sodium fluoride.

Materials and Methods

In Milwaukie and Oregon City, Oreg., a questionnaire was sent to the parents of all children in grades 4 through 9. The questionnaire was used to obtain parental permission for the children to take part in the study and to identify children who had had previous exposure to fluoride. The parents of 69 percent of the children in the 5 grades requested that their children participate in the study. All these children were included except those whose questionnaires indicated that they had previously received topical fluoride applications or had lived at some time in an area having more

than 0.3 ppm of fluoride ion in the water supply. The fluoride content of the public water supply in Milwaukie was 0.25 ppm; in Oregon City, it was 0.20 ppm.

The names of 690 children who were to participate were listed alphabetically by age and sex. Every other child was assigned to one treatment group and the remainder to a second treatment group. In alternate children within each of these groups, the right quadrants received the treatment, and in the remainder, the left quadrants. No selection was made on the basis of caries susceptibility.

A dental prophylaxis was given prior to the initial examination. All examinations were made in December 1955 by the authors, with No. 4 plane mouth mirrors and No. 23 single-end explorers under artificial light. Portable dental chairs were used. Compressed air was applied routinely to each quadrant during examination.

Both fluoride solutions were applied four times by the same dental hygienist, using the method described by Knutson (15). The treatments were begun in January 1956 and completed within 4 months. One group of children received a 2 percent aqueous, unbuffered sodium fluoride solution. The other group received a 2 percent aqueous, unbuffered stannous fluoride solution. In all children, the solution being tested was applied to one side of the mouth, and distilled water to the other side. Celluloid strips were used between the central incisors, both upper and lower, to help prevent the fluoride solution from contacting the untreated side. The sodium fluoride solution was prepared daily. The stannous fluoride solution was prepared hourly with oxygen-free distilled water, since it deteriorates rapidly (16, 17).

Dr. Nevitt was regional dental consultant for the Public Health Service in Region 9, San Francisco, when this study was conducted. He is currently on a 1-year assignment as dental health adviser with the World Health Organization in its Eastern Mediterranean Regional Office, Alexandria, Egypt. Dr. Witter is director of the dental health section, Oregon State Board of Health, Portland, and Dr. Bowman, formerly a dental officer with the Public Health Service in Region 9, is now in private practice in Richmond, Calif.

for more support for preventive activities by official agencies. Prevention is still cheaper than compensation.

Table 3. Percentage fewer newly carious teeth and tooth surfaces during a 16-month period in permanent teeth of fluoride-treated mouth quadrants of 588 children, Milwaukie and Oregon City, Oreg.

Fluoride solution	Percentage fewer newly carious teeth			Percentage fewer newly carious surfaces of previously carious teeth		
	Upper arch	Lower arch	Both arches	Upper arch	Lower arch	Both arches
Stannous fluoride.....	46.3	41.3	44.4	9.1	11.8	10.4
Sodium fluoride.....	33.5	40.6	35.9	5.4	15.5	10.3

than among the untreated teeth regardless of the fluoride solution used.

In the upper arch, a smaller proportion of caries-free permanent teeth became carious after treatment with stannous fluoride than after treatment with sodium fluoride. This difference is statistically significant. In the lower arch, the proportion of caries found in teeth treated with stannous fluoride is not significantly different from the proportion in those treated with sodium fluoride. Neither is there a significant difference in caries incidence between the two types of treatment when the data for both arches are combined.

The reduction in the incidence of dental caries on tooth surfaces of previously carious teeth was not significant for either the sodium or stannous fluoride solutions.

As long as 4 months elapsed between the initial examination and the beginning of treatment of some children. If each child had received treatment immediately following examination, the demonstrated effectiveness of the fluoride solutions might have been greater than that observed in this study.

Summary

Two groups of school children 9-14 years of age were given topical applications of stannous fluoride and sodium fluoride to test the effectiveness of these preparations as dental caries preventives. One group was treated with a 2 percent stannous fluoride solution and the other with a 2 percent sodium fluoride solution. The upper and lower quadrants on one side of the mouth were treated, and the quadrants on the other side served as controls.

Analysis of data on 588 children reexamined 16 months after the initial examination indicated that:

1. The incidence of dental caries in permanent noncarious teeth was significantly lower in mouth quadrants treated with either stannous fluoride or sodium fluoride than in untreated quadrants.

2. The findings relative to the comparative effectiveness of stannous fluoride and sodium fluoride were inconclusive.

Table 1. Age distribution of 588 children available for reexamination at the end of a 16-month period, Milwaukie and Oregon City, Oreg.

Fluoride solution ¹	Number of children by age (last birthday) at time of first examination.						
	9	10	11	12	13	14	All ages
Stannous fluoride—	29	19	21	71	66	84	290
Sodium fluoride—	35	23	18	58	76	88	298
Total—	64	42	39	129	142	172	588

¹ All children received four applications.

Of 671 children treated in the study, 588 were available for reexamination in April 1957, 16 months after the first examination. Of these 298 were treated with sodium fluoride and 290 with stannous fluoride. Each of the dentists examined the same children he had examined originally. Equipment and procedures used for the reexamination were identical with those of the first examination. New record cards were prepared so that the examiner would not know the results of his first examination nor which solution had been used. A prophylaxis was given before the second examination to remove any stains that might have developed from the application of stannous fluoride.

In this discussion, analysis of the data on caries experience is confined to the erupted per-

manent teeth seen at the time of the initial examination. The age classification refers to the age (last birthday) at the time of the first examination (table 1).

Results

The caries experience of the 588 children available for the second examination is shown in table 2, and the percentage reduction in the incidence of newly carious teeth and of carious surfaces in previously carious teeth is given in table 3.

Of 1,087 upper permanent noncarious teeth treated with stannous fluoride, 131, or 12 percent, became carious. In the untreated quadrants, 244 of 1,084 teeth, or 23 percent, became carious. The proportion of teeth that became carious is significantly lower among the treated than among the untreated teeth.

Of the 1,103 upper permanent noncarious teeth that were treated with sodium fluoride, 171, or 16 percent, became carious. Again, the proportion of treated teeth that became carious is significantly lower among the treated than among the untreated teeth.

There were more noncarious permanent teeth in the lower arch of the 588 children than in the upper arch, and a smaller percentage of the teeth in this arch became carious whether treated or not. However, in the lower arch as in the upper one, the proportion of newly carious teeth is significantly lower among the treated

The Public Health Program for Mexican Migrant Workers

NORMA J. ROBINSON

CONTINUAL EFFORT has been made by the Public Health Service to identify the health problems and to establish specific health requirements for migrant laborers coming into this country.

Of the 1¼ million migrant laborers employed in agriculture in the United States, approximately one-half million are foreign nationals, principally from Mexico. The Mexican component is about 450,000. Those who are recruited in Mexico for brief periods of time to meet a specific need are called *braceros* (from the Spanish word for "arm"). During 1957, *braceros* were employed in 27 States, ranging from California on the west coast to Delaware in the east.

The program for employment of foreign labor in the United States requires that each worker pass a physical examination. Today, the Public Health Service has developed a procedure for screening large numbers of laborers in a relatively short period of time.

Early Recruitment

Mexico has been a source of labor for the United States for many years. For a long period, however, this recruiting was unsupervised. Workers were brought in without adequate guarantees as to employment, housing, sanitary conditions, and wages. The working conditions and ultimate economic status of many of the Mexican laborers in the United

States became a serious problem for this country and for Mexico. Particularly during the period of economic depression following 1929, distress was general among the Mexican residents in the United States; consequently, many of the laborers returned to Mexico in various degrees of destitution. The Mexican Government was therefore prompted to incorporate in the Mexican Federal Labor Law of 1931 definite regulations governing the migration of Mexican workers, and the Mexican Constitution outlined these workers' rights, including compensation for injuries or illnesses and the guarantee of return transportation for workers given contracts for employment outside the country (1a). This official act had a marked impact on the emigration of laborers and the establishment of standards for the employment of Mexican agricultural workers.

Historically, the Division of Foreign Quarantine of the U. S. Public Health Service has had specific responsibility for preventing the introduction of quarantinable and other dangerous and contagious diseases into the United States and for preventing the entry of aliens with mental and physical conditions excludable under the immigration laws. Prior to World War II, medical inspections of Mexican nationals entering the United States were performed at the ports of entry along the Mexican border. For the temporary visitor, the medical inspection was rather cursory. However, it appears that particular attention was given to inspecting for pediculosis to prevent the introduction of typhus fever, and disinfestation was frequent. Mexican nationals were permitted to

Institute of Perinatal Casualties

An institute on perinatal casualties will be held jointly on December 8-12, 1958, by the University of Michigan School of Public Health and the University of Minnesota School of Public Health in Minneapolis, Minn. Michigan and Minnesota State maternal and child health and crippled children's agencies are also sponsors.

The institute will consist of a series of seminars and discussions on such aspects of perinatal casualties as definition, extent and significance; etiology; prevention; growth and development; coordination of services; mortality studies; care of the premature infant; specialized programs, such as mental retarda-

tion, cerebral palsy, and congenital heart disease; and program planning and evaluation.

Each State in Regions V and VI may select, at least four staff members (two each from MCH and crippled children's programs) to attend the institute. Travel expenses, tuition, lodging, and meals of each person selected will be financed by the U. S. Children's Bureau.

For further information Region V applicants should contact Dr. Donald C. Smith, University of Michigan School of Public Health, Ann Arbor, Mich., and Region VI applicants should contact Dr. Helen M. Wallace, University of Minnesota School of Public Health, Minneapolis, Minn.

United States illegally obviously could not have been examined.

In 1949 the international executive agreement between Mexico and the United States included a significant change which seriously affected the medical examination of Mexican laborers. Under this agreement, laborers illegally in the United States could be recruited and contracted for agricultural work. Subsequent recruiting of wetbacks in the United States was carried out sporadically in scattered areas to meet the labor needs of particular localities. Under these conditions, the Division of Foreign Quarantine could not make complete examinations for tuberculosis. Although the Service could not conduct a comprehensive medical examination program for the illegal entrants, laborers who were recruited in Mexico were given medical examinations at the designated ports of entry, according to the terms of the 1949 agreement.

Legislative Authority

For several years the Mexican Government had been seeking agreements which would prevent the illegal exodus of Mexican workers and protect, with respect to wages and working conditions, its citizens employed in the United States. To insure that the United States would promptly and effectively support compliance with the obligations in the work contracts between employer and employee, the Mexican Government requested that the United States adopt legislation to authorize a United States Government agency to contract workers. Public Law 82-78 giving the legislative authority to employ agricultural workers from the Republic of Mexico was passed on July 12, 1951.

This legislation gave the Secretary of Labor the responsibility for bringing from Mexico agricultural workers subject to United States immigration laws. The Public Health Service, with responsibility for performing the physical and mental examinations of arriving aliens for the Immigration Service, continued to carry out the medical program for the Mexican laborers.

Following enactment of the new law, Mexico and the United States entered into the Migrant Labor Agreement of 1951. This agreement allowed establishment of migratory centers in

Mexico and reception centers in the United States to recruit and contract Mexican laborers. Both Public Law 78 and the Migrant Labor Agreement have been extended periodically. The present legislative authority will expire on June 30, 1959.

Medical Examination

It was agreed that the Public Health Service would conduct at the migratory centers in Mexico a physical and mental examination of each laborer to assure that he met the mental and health requirements for admission to the United States. If facilities were available, each laborer would be physically examined and given a photofluorographic chest X-ray, with modern equipment, and a serologic test. Service physicians were to be assisted by Mexican physicians who would later replace them. In accordance with the agreement, the migratory centers in Mexico were to be located at Aguascalientes, Aguascalientes; Guadalajara, Jalisco; Irapuato, Guanajuato; Monterrey, Nuevo Leon; and Chihuahua, Chihuahua.

On September 13, 1951, Public Health Service personnel and equipment for the photofluorographic activities at the migratory centers in Irapuato, Guadalajara, and Aguascalientes were dispatched to Mexico. However, inadequate electric power for operating fluorographic equipment made X-raying impossible. At Aguascalientes and Guadalajara it was reported that electric power could not be brought to buildings housing the X-ray equipment. In addition, power stations were reportedly shut down during daylight hours, and Service personnel were advised that there were troublesome voltage variations in the local municipal systems. During the period from September 13 to October 17, 1951, no X-rays were made. Because of these difficulties, it was concluded that the program had to be performed at the reception centers in the United States.

By October 31, 1951, approximately 120,000 laborers had been admitted to the United States without receiving chest X-rays. As a solution, the photofluorographic equipment was moved from the migratory centers in Mexico to reception centers in the United States. At Eagle Pass, Tex., the first X-rays were taken on No-

enter the United States as temporary visitors for work on farms during limited periods.

During World War II

At the beginning of World War II, demands for personnel in the war industries and the armed services created labor shortages, particularly in agriculture. The Mexican Government was requested to provide Mexican laborers for agricultural work in the United States, and in July 1942 that government consented to grant labor assistance as a part of its contribution to the war effort.

During and following World War II, the responsibility for the Mexican labor recruitment program was assigned to several United States agencies, such as the Farm Security Administration, the War Manpower Commission (with the U. S. Employment Service and U. S. Selective Service), and various branches of the U. S. Department of Agriculture (1*b*). Within the administrative framework of the Farm Security Administration, and subsequently the War Food Administration, provision was made for carrying out a medical program for the agricultural workers. Accordingly, funds for the medical examination program were transferred from the responsible agency to the Division of Foreign Quarantine, Public Health Service.

Teams of Public Health Service medical officers from the Foreign Quarantine, Venereal Disease Control, and Tuberculosis Divisions were sent to Mexico to carry out examinations in cooperation with Mexican health officials.

According to a Public Health Service report on the history of the physical examinations, these officers followed traditional medical procedures used for immigrants. The workers were examined for conditions of the skin, heart, lungs, and teeth and for venereal diseases. Tests were also made of the eyes, ears, nose, and throat, the blood pressure, and the general skeletal, muscular, and nervous systems. Most laborers were vaccinated or revaccinated for smallpox and given initial typhoid inoculations. In addition, photofluorographic chest X-rays and serologic tests were given to prospective laborers when facilities permitted.

When the war emergency program began, the selection of eligible laborers was carried out in Mexico City, a practice which made possible a

centralized examination program. However, at the end of 1944 the selection center moved from Mexico City to Irapuato, and subsequently, other selection centers were established and operated at the discretion of the Mexican Government (1*c*). Medical personnel with mobile X-ray units were sent from the Public Health Service to the recruiting points within Mexico, where numerous problems arose in operating the units (2). After 1 or 2 years of experience, Public Health Service medical officers were sent to the recruiting points in Mexico solely to assist local physicians in X-ray and other medical procedures connected with the examinations.

After World War II

Following World War II, recruiting continued under the provisions of international executive agreements between Mexico and the United States. Unfortunately, these agreements frequently were delayed until the need for such laborers in the United States was acute, and without an agreement, Mexican citizens could not be legally recruited. At the same time it was known that there were Mexican citizens entering the United States illegally for agricultural work.

According to a U. S. Department of Labor report, the number of Mexicans who entered this country illegally (wetbacks) increased from 29,000 in 1944 to 565,000 in 1950 (3). Both countries were concerned about the problem, but the Mexican border, approximately 1,600 miles in length, proved to be difficult to patrol effectively. There were then nine official crossing points along the Mexican border which were staffed by Public Health Service personnel. Although the Immigration Service was guarding the border, the number of patrol officers was not sufficient to force all to enter at the legal crossing points.

It was realized from the start that to give a medical examination, including chest X-ray, to each laborer who entered the United States was impossible. This was especially true during accelerated recruiting activities immediately after the signing of an international executive agreement. In addition, the large segment of the Mexican migrant labor force entering the

United States illegally obviously could not have been examined.

In 1949 the international executive agreement between Mexico and the United States included a significant change which seriously affected the medical examination of Mexican laborers. Under this agreement, laborers illegally in the United States could be recruited and contracted for agricultural work. Subsequent recruiting of wetbacks in the United States was carried out sporadically in scattered areas to meet the labor needs of particular localities. Under these conditions, the Division of Foreign Quarantine could not make complete examinations for tuberculosis. Although the Service could not conduct a comprehensive medical examination program for the illegal entrants, laborers who were recruited in Mexico were given medical examinations at the designated ports of entry, according to the terms of the 1949 agreement.

Legislative Authority

For several years the Mexican Government had been seeking agreements which would prevent the illegal exodus of Mexican workers and protect, with respect to wages and working conditions, its citizens employed in the United States. To insure that the United States would promptly and effectively support compliance with the obligations in the work contracts between employer and employee, the Mexican Government requested that the United States adopt legislation to authorize a United States Government agency to contract workers. Public Law 82-78 giving the legislative authority to employ agricultural workers from the Republic of Mexico was passed on July 12, 1951.

This legislation gave the Secretary of Labor the responsibility for bringing from Mexico agricultural workers subject to United States immigration laws. The Public Health Service, with responsibility for performing the physical and mental examinations of arriving aliens for the Immigration Service, continued to carry out the medical program for the Mexican laborers.

Following enactment of the new law, Mexico and the United States entered into the Migrant Labor Agreement of 1951. This agreement allowed establishment of migratory centers in

Mexico and reception centers in the United States to recruit and contract Mexican laborers. Both Public Law 78 and the Migrant Labor Agreement have been extended periodically. The present legislative authority will expire on June 30, 1959.

Medical Examination

It was agreed that the Public Health Service would conduct at the migratory centers in Mexico a physical and mental examination of each laborer to assure that he met the mental and health requirements for admission to the United States. If facilities were available, each laborer would be physically examined and given a photofluorographic chest X-ray, with modern equipment, and a serologic test. Service physicians were to be assisted by Mexican physicians who would later replace them. In accordance with the agreement, the migratory centers in Mexico were to be located at Aguascalientes, Aguascalientes; Guadalajara, Jalisco; Irapuato, Guanajuato; Monterrey, Nuevo Leon; and Chihuahua, Chihuahua.

On September 13, 1951, Public Health Service personnel and equipment for the photofluorographic activities at the migratory centers in Irapuato, Guadalajara, and Aguascalientes were dispatched to Mexico. However, inadequate electric power for operating fluorographic equipment made X-raying impossible. At Aguascalientes and Guadalajara it was reported that electric power could not be brought to buildings housing the X-ray equipment. In addition, power stations were reportedly shut down during daylight hours, and Service personnel were advised that there were troublesome voltage variations in the local municipal systems. During the period from September 13 to October 17, 1951, no X-rays were made. Because of these difficulties, it was concluded that the program had to be performed at the reception centers in the United States.

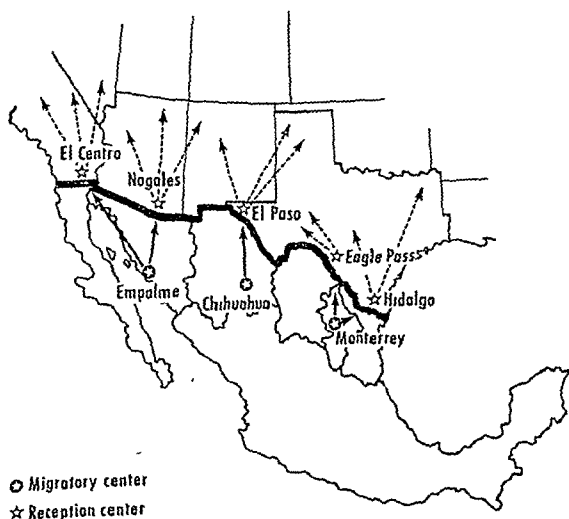

By October 31, 1951, approximately 120,000 laborers had been admitted to the United States without receiving chest X-rays. As a solution, the photofluorographic equipment was moved from the migratory centers in Mexico to reception centers in the United States. At Eagle Pass, Tex., the first X-rays were taken on No-

vember 4, 1951. Photofluorographic equipment was installed at the reception centers in El Paso and Harlingen, Tex., and El Centro, Calif., and was in operation about 30 days after the establishment of the X-ray program at the Eagle Pass reception center.

The reception centers were successful in taking only 8,028 X-rays during the rush season. The reason for this limited number was that the majority of laborers had received contracts when the difficulties were being encountered in Mexico and before it was possible to install photofluorographic equipment at the reception centers in the United States. Many of the laborers X-rayed had already been in the United States and were returning to the reception centers to be recontracted.

Migratory and Reception Centers

There are, then, two types of migratory labor processing centers: migratory centers in Mexico and reception centers within the United States along the Mexican border. The reception centers in the United States now are at Hidalgo, Eagle Pass, and El Paso, Tex.; Nogales, Ariz.; and El Centro, Calif. In Mexico the number and the location of the migratory centers are influenced by the demand for laborers. During fiscal year 1957, Mexico's migratory centers were at Empalme, Sonora; Monterrey, Nuevo Leon, and Chihuahua, Chihuahua. Each migratory center recruits the laborers in accordance with requests received from the reception centers.

Until 1954, illegal entrants from Mexico continued to pose a serious problem. While the recruiting program contracted about 200,000 laborers under the terms of the international agreement during 1953, it was estimated that approximately 1 million Mexicans crossed the border illegally to accept employment.

In 1954, the U. S. Department of Justice increased the number of border patrol officers and took other effective measures leading to the gradual decline in the illegal entry of Mexican laborers.

A concomitant change occurred in the number of laborers recruited to fill the gap produced by the decline in illegal immigration. Based on experience, the U. S. Department of Labor had planned to request 260,000 laborers from Mexico during fiscal year 1955; however, it was necessary to recruit 350,000 laborers during that year in order to meet the demand. The number of laborers contracted each year has continued to increase, as indicated by the 428,416 laborers during fiscal year 1956 and 450,162 laborers during fiscal year 1957. Today the wetback problem has been largely resolved, and braceros are provided by the controlled farm labor program.

Current Medical Program

The action taken to control illegal immigration has made possible the conduct of an effective medical program for Mexican laborers. Since 1954, every laborer contracted by the U. S. Department of Labor has been given a medical examination. In addition, the medical program is geared to meet the increases in the need for agricultural workers, without sacrificing the quality of the medical examinations.

The entire medical program for Mexican laborers at the migratory centers in Mexico and the reception centers in the United States is carried out under the direction of the Public Health Service medical officer assigned to the district quarantine station, El Paso, Tex. Mexican doctors and nurses are employed to perform the medical examinations at the migratory centers in Mexico, and Public Health Service doctors and a limited number of contract doctors conduct the medical program at the reception centers in the United States.

The medical examination at the migratory centers in Mexico is essentially a screening process. On the basis of clinical diagnosis, laborers who have tuberculosis, venereal diseases, or other conditions making them unfit for accepting employment in the United States are rejected. Those who pass the physical examination are vaccinated for smallpox. The vaccine is provided by the Mexican Government without cost to the United States farm placement program.

The primary purpose of the physical examinations at migratory centers in Mexico is to eliminate unnecessary hardships for the Mexican laborers. Those who are rejected at the migratory centers are spared the trip to the reception center and the disappointment of being rejected and returned to the migratory center. In addition, the Mexican physicians at the migratory centers aid the laborers in finding medical care, frequently at the office of the Mexican health service, for remediable conditions. The record of medical rejections at the migratory centers for the fiscal years 1952 through 1957 is shown in table 1.

Laborers who pass the physical examination at the migratory centers are transported, under the supervision of the U. S. Labor Department, by railroad or bus to the reception centers. There they are first processed by the Public Health Service personnel. Each laborer and his personal effects are dusted with an insecticide. The laborer is then examined for evidence of venereal disease, given a photofluorographic chest X-ray, and examined for any other physical conditions which would be contagious or make the laborer unfit for agricul-

tural work. All laborers with evidence of venereal disease are routinely treated, and most of them are then permitted to accept employment. However, when a venereal disease case cannot be cured with a single treatment, the laborer is rejected and returned to Mexico.

All laborers with tuberculosis, contagious diseases, or other disqualifying physical defects are rejected and returned to the migratory centers in Mexico. In accordance with the joint operating instructions between the United States and the Mexican Government, effective July 1, 1956, laborers rejected at the reception centers must be reported to the Mexican consul. The Public Health Service doctor at the reception center gives the worker and the Mexican consul a written diagnosis of the case so that the information may be transmitted to the appropriate Mexican authorities. The medical causes for rejection and the number of laborers rejected at the reception centers for the fiscal years 1952 through 1957 are shown in table 2.

Medical Program Cost

Employers of Mexican laborers reimburse the United States Government for all expenses of the Mexican farm labor program, except costs of U. S. Department of Labor personnel, through a revolving fund to which employers pay a fixed fee per worker hired. The remainder of the fund is made up of Department of Labor appropriations. Since 1954 the costs of medical examinations of Mexican laborers have been charged to that fund.

Medical expenses are incurred for (a) medical examinations and vaccinations performed

Table 1. Medical rejections at the migratory centers for fiscal years 1952 through 1957

Fiscal year	Number of laborers examined	Medical causes for rejection				Total rejected	Rate of rejection
		Mental	Tuberculosis and pulmonary conditions	Venereal disease	Other conditions		
1952	187, 569	5	29	373	3, 206	3, 613	1. 92
1953	205, 941	70	93	588	7, 033	7, 784	3. 77
1954	180, 871	1	27	391	5, 432	5, 851	3. 23
1955	263, 376	0	52	1, 189	4, 353	5, 594	2. 12

1957	440, 332	3	35	1, 808	3, 741	5, 587	1. 26

Table 2. Medical causes for rejecting Mexican migrant laborers and number rejected at the reception centers during fiscal years 1952 through 1957

Fiscal year	Number of laborers examined	Medical causes for rejection				Total rejected	Rate of rejection
		Mental	Tuberculosis and pulmonary conditions	Venereal disease	Other conditions		
1952-----	333, 071	12	676	75	116	879	0.26
1953-----	292, 891	39	2, 536	523	764	3, 862	1.3
1954-----	221, 119	23	2, 724	188	658	3, 593	1.6
1955-----	340, 070	9	4, 357	271	1, 132	5, 769	1.7
1956-----	435, 332	13	5, 277	16	451	5, 757	1.3
1957-----	457, 360	14	5, 050	98	416	5, 578	1.2

at the migratory centers in Mexico, (b) hospital and medical care for laborers who are injured or become ill between migratory centers and the reception center or at the reception center, and (c) medical examinations performed at the reception centers in the United States.

The Foreign Quarantine Division conducts the entire medical program at a minimal cost to employers. During fiscal year 1957 Mexican laborers were examined at the migratory centers in Mexico at a cost of approximately 20 cents per laborer. The complete medical examinations, including chest X-rays, at the reception centers in the United States, for 457,360 laborers amounted to approximately 73 cents per laborer. The medical examinations at the migratory centers in Mexico, hospital and medical care provided by the Public Health Service, and medical examinations at the reception centers in the United States were performed, on the average, for 95 cents per laborer receiving a contract for employment in the United States.

Today the medical program for the examination of Mexican laborers conducted by the quarantine service is effective because many of the problems plaguing efforts to conduct a complete medical program during and after World War II have been resolved. Control of illegal labor immigration, development of new techniques and equipment, and research have all contributed to the success of the present medical program. However, the program is subjected to continuous review and analysis in order to improve further the techniques and

procedures and to resolve the challenging problems still encountered.

Venereal Disease Program

For many years the Public Health Service and certain State health departments have been concerned about the possible importation of venereal infections into the United States by immigrants. In the examination program for Mexican laborers, the venereal disease aspect has received considerable attention. Mexican laborers recruited since the early part of World War II have been medically examined, and, whenever laboratory facilities have been available, have been given serologic tests for the detection of syphilis.

Prior to 1951 all serologic tests were performed in Mexico. However, in 1951 the migratory labor agreement between Mexico and the United States permitted Public Health Service physicians to carry out such examinations and treatment of positive cases of syphilis.

Since the beginning of fiscal year 1955, the Venereal Disease Program in cooperation with the Division of Foreign Quarantine, the Department of Labor, and several State health departments has serologically screened more than 300,000 migrant agricultural workers from Mexico. The annual figures are as follows:

Fiscal year	Number tested	Number reactors	Percent reactive
1955-----	24, 750	2, 611	10.6
1956-----	31, 712	2, 914	9.2
1957-----	165, 355	12, 559	7.6
1958 ¹ -----	96, 376	8, 008	8.3

¹ 7 months.

Screening of the migrant group for syphilis has been hindered by the fact that the blood specimens had to be mailed to distant laboratories for testing and the braceros were dispersed to various working localities before the test results were known. The reactors had to be traced to their place of work and brought in for diagnosis before they could be treated for syphilis. This procedure involved costly fieldwork and complicated recordkeeping. The Venereal Disease Program has solved this problem by developing a rapid blood test that gives immediate on-the-spot results. The new test, known as the rapid plasma reagin (RPR) test, is now being demonstrated in the Mexican-migrant testing program at El Centro, Calif., and reactive cases are detected immediately, diagnosed, and treated. Thus the need for field investigation work and records has been entirely eliminated.

In addition to diagnostic and treatment services provided at the El Centro reception center, epidemiological reports are prepared on marital contacts of venereally infected braceros and referred to State health departments in Mexico for followup.

Recently the Public Health Service presented to representatives of the U. S. Department of Labor and to growers concerned with the farm labor program of Mexico a plan for conducting a serologic screening service at the reception centers. This plan was unanimously approved although the screening as proposed means some additional cost to the growers. The demonstration project in El Centro was taken over by the Division of Foreign Quarantine on July 1, 1958, and similar activities are expected to start by September 1 at the three other large reception centers on the border. The Venereal Disease Branch of the Communicable Disease Center, Public Health Service, is assisting the Division of Foreign Quarantine by supplying personnel to advise on program requirements, to help train laboratory workers in RPR testing, and to assist in initiating the program at the other centers.

Photofluorographic X-rays

To the extent that X-ray facilities have been available and Mexican laborers legally recruited, it has been possible to prevent Mexican

laborers with tuberculosis from entering the United States. As effective control measures were taken to prevent illegal migration from Mexico, the number of laborers who were X-rayed and rejected under a controlled recruitment program continued to increase. Only 61,654 Mexican laborers were X-rayed during 1952 as compared with the 457,360 Mexican laborers in 1957.

Efforts were directed to establishing a complete X-ray program following the decision to carry out the X-ray program at the reception centers in the United States rather than at the migratory centers in Mexico. Because the X-ray activities required more time than any other phase of the examination, developing the most efficient methods of operation was emphasized. Today peak workloads of approximately 4,000 laborers per day are processed by achieving maximum capacity from each machine. The records reveal that two X-ray machines have taken as many as 5,400 photofluorograms during one 24-hour period. The total process, taking photofluorograms, developing the film, and reading the X-rays, has been accomplished at the reception centers without time delays.

While the laborers are at the reception centers, the photofluorograms are read by physicians with special training in radiology. When the X-ray reveals that a laborer has tuberculosis, the laborer is returned to Mexico. During the fiscal years 1952 through 1957, approximately 20,000 Mexican laborers were returned for that reason.

The rate of rejection of laborers with tuberculosis appears to be declining. Of the total examined, 1.22 percent were returned during fiscal years 1954 and 1955, 1.14 percent during 1956, and 1.07 percent during 1957.

In the past, one cause of a slowdown in the X-ray work had been the need to make 14" x 17" X-ray plates whenever the 70 mm. photofluorogram suggested tuberculosis or any other disqualifying condition. A recently developed X-ray camera improves the quality of the film to the extent that 14" x 17" X-ray plates are no longer necessary. In addition to saving the cost of the 14" x 17" X-ray plates, the new camera decreases the radiation exposure to about one-third of that received from the pres-

ent equipment. Plans are being made to install this camera at all reception centers.

Louse Control

The human body louse is the well-known transmitter of typhus, one of the six quarantinable diseases. In the course of careful control activities against the insect, including disinfestation with DDT, the question of louse resistance to that insecticide arose.

Historically, DDT-resistant body lice were first observed in Korea in 1951. The insecticide, used so effectively throughout the world in the control of lice, and certain others used since 1945 were no longer effective in the control of body lice in that war area. It was found, however, that lindane brought satisfactory control. Also, an insecticide mixture containing pyrethrum, used for many years in insect control work, proved effective against DDT-resistant lice. Unfortunately, however, it was found that pyrethrum does not possess the highly desirable residual quality of DDT and lindane.

Further, findings in 1953 from a survey of the World Health Organization showed an alarming degree of insecticide resistance, particularly to DDT, in the lice studied in a number of countries. This survey found resistance to DDT in body lice in Mexico and reported a few instances of louse resistance to lindane and even to pyrethrum, findings corroborated in more recent studies.

During February and March 1957, the Public Health Service conducted at El Centro, Calif., tests which showed moderate resistance to DDT. When lice were exposed for 24 hours to 0.1 percent DDT in 4 tests, the survival rate ranged from 32 percent to 100 percent. The average survival in these 4 tests was 59.0 percent. When 0.5 percent DDT was used in 6 tests, the survival rate ranged from 9.0 percent to 37.0 percent, with an average of 20.0 percent. Application of 1.0 percent DDT in 6 tests showed a survival rate ranging from 8.0 percent to 35.0 percent, with an average of 20.0 percent. Use of 5.0 percent DDT in 4 tests provided survival rates ranging from 3.0 percent to 40.0 percent, with an average of 25.0 percent. In all tests at least moderate resistance to DDT was exhibited by the lice. These findings are supported by results of studies conducted since.

At least for the present, the use of DDT in louse control work along the Mexican border has been abandoned, and although lindane appears satisfactory now, possibly within the next year or two this insecticide may suffer the same fate. New insecticides must be ready for use at that time. Otherwise, it may become necessary to revert to the cumbersome and expensive louse-control methods used prior to DDT. In that era, clothing, bedding, and other items were treated with steam or dry heat in specially constructed autoclaves or with chemicals such as hydrocyanic acid gas or chloropicrin. Persons were treated with kerosene emulsion soap and other similar crude formulations.

Scientists and insecticide manufacturers throughout the world are striving to find insecticides that may be effectively and safely employed in louse control. The actual efficacy and, particularly, the safe use of new insecticides for the control of body lice on human beings remains to be demonstrated, first in the laboratory and then under operational conditions in the field. The Division of Foreign Quarantine is now planning a research program for studies which will lead to a solution of the insecticide resistance problem.

In spite of setbacks from insecticide resistance, the Foreign Quarantine Division's louse control activities have had some measure of success. It was the opinion of professional personnel making the medical examinations of Mexican laborers in 1951 and 1952 that as many as one-half of the Mexican laborers were suffering from pediculosis. A careful inspection of a number of Mexican laborers during 1956 showed infestation to be only about 10 percent.

Smallpox Vaccination

Mexican laborers are vaccinated against smallpox in compliance with the Public Health Service requirements. Until recently, Mexican laborers were vaccinated each year without regard to previous vaccinations even though the recognized period of immunity after a successful immunization is 3 years. The practice of revaccinating many of the laborers upon reentry was adopted as the most expeditious means of insuring that all laborers were immunized. During the past year the U. S. Department of Justice has adopted the practice

of issuing identification cards on which the date of the smallpox vaccination is stamped. After the Mexican laborers are issued identification cards, they will be revaccinated only at the end of a 3-year period. The revised procedure will provide the necessary immunization against smallpox and, at the same time, reduce the amount of vaccine and personal services needed previously to vaccinate all laborers annually.

Medical Care Program

The Division of Foreign Quarantine provides emergency medical care for Mexican workers who become ill while enroute from the migratory centers in Mexico or who otherwise need emergency medical care while at the reception centers in the United States. Nearby hospitals have been contracted to care for the laborers who develop serious or prolonged illnesses. The need for hospital care is determined by the medical personnel at the reception centers. Expenditures for hospitalization have been extremely low in comparison with the number of laborers who enter the reception centers each year. The cost of hospitalization was \$9,331 during fiscal year 1955, \$12,586 during 1956, and only \$5,649 during 1957.

The requirements for emergency medical care at the reception centers have always been unpredictable. In 1957, an unprecedented need for this care occurred when the Asian influenza became epidemic among the Mexican laborers. A total of 4,122 cases of influenza was reported by the reception centers from August 3 through October 11, 1957. Because of the short duration and mildness of the illness, the patients usually did not require hospitalization, and it was necessary to provide medical care at the reception centers. During the height of the epidemic the medical personnel frequently worked round-the-clock. Only two laborers were sent to contract hospitals for treatment.

After the Mexican laborer has been contracted and leaves the reception center, the employer is responsible for providing medical care. The laborer, while employed in the United States, is given the same guarantees with respect to medical care and compensation that are provided to domestic agricultural

workers under applicable State laws. In the absence of such laws, the employer must either obtain an insurance policy or supply an indemnity bond to secure the payment of benefits, including medical, surgical, and other necessary care and treatment, for work-connected illness or injury. In addition to insuring the laborer against occupational risks, the employer must also obtain life and nonoccupational insurance for the Mexican workers. However, the premiums for the latter insurance are deducted from the Mexican worker's wages.

Summary

The recruitment of Mexican laborers, originally a war emergency measure at the beginning of World War II, has become an established program. Mexican laborers are considered essential in the production of agricultural products in the United States, and during 1957 they were employed in 27 States. At present, Mexican laborers represent approximately two-fifths of all the migrant laborers (United States and foreign) employed in the United States.

Since the start of recruitment in 1942, a specific program for the medical examination of these laborers has been carried out by the Public Health Service. However, for many years the Mexican labor program was fraught with unique problems precluding the most effective conduct of its medical phase. The progress of such a program depended upon the establishment of effective international agreements between the United States Government and the Mexican Government. The United States Government, moreover, had to enact special legislation on the employment of Mexican nationals and had to take effective measures to prevent the illegal immigration of laborers into the United States.

Since 1954 every Mexican laborer who has received a contract for employment in the United States has been dusted with an insecticide, vaccinated, examined for evidence of venereal disease, given a photofluorographic chest X-ray, and examined for any other condition which would make the laborer inadmissible or unfit for agricultural work.

Of the challenging problems in the medical

examination program, louse control is one of the most significant. Scientists throughout the world are searching for new insecticides that may be effectively and safely employed in louse control, and the quarantine service is planning to participate in the laboratory research. The Public Health Service continues to seek new methods to improve the present program in order to prevent the introduction of dangerous contagious diseases into the United States.

Rehabilitation of the Deaf-Blind

Publication of a manual to guide the rehabilitation of the deaf-blind was announced at a meeting June 19, 1958, in Washington, D. C., sponsored by the Industrial Home for the Blind in Brooklyn, N. Y., and the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare. This book for professional workers is the first such major effort in the United States for the rehabilitation of the deaf-blind.

The manual is the result of 2 years of study and research by the staff of the home and other specialists, supported by a research grant from the Federal agency. It is primarily a summary report of the pilot study, treating rehabilitation of the deaf-blind in simple language. Later volumes will discuss more technical aspects.

At the Washington meeting, Miss Mary E. Switzer, director of the Office of Vocational Rehabilitation, received the first copy of the manual from Peter J. Salmon, executive director of the home. Miss Switzer, pointing out that the key to rehabilitation of the deaf-blind is communication, said that one of the easiest methods is the recently developed international standard manual alphabet, now recommended for worldwide use. In this system, the communicator uses an index finger to outline standard block letters in the palm of the recipient.

A member of the home's staff, Robert J. Smithdas, who holds a master's degree although he has been blind and deaf since child-

Peter J. Salmon uses a grease pencil to demonstrate the new international standard manual alphabet. Robert J. Smithdas is the "reader." In actual practice, letters are merely traced in the palm of the hand.

hood, demonstrated the system at the meeting. Others attending the gathering were representatives of Gallaudet College and other organizations concerned with the blind and the deaf.

Copies of *Rehabilitation of Deaf-Blind Persons: A Manual for Professional Workers* are available from the Industrial Home for the Blind, 127 Willoughby St., Brooklyn, N. Y.

Milk Sanitation Honor Roll for 1956-58

Eighty-five communities have been added to the Public Health Service milk sanitation "honor roll," and 51 communities on the previous list have been dropped. This revision covers the period from July 1, 1956, to June 30, 1958, and includes a total of 283 cities and 87 counties.

Communities on the honor roll have complied substantially with the various items of sanitation contained in the milk ordinance suggested by the U. S. Public Health Service. The State milk sanitation authorities concerned report this compliance to the Public Health Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk are sold.

The suggested milk ordinance, on which the milk sanitation ratings are based, is in effect through voluntary adoption in 480 counties and 1,400 municipalities. The ordinance also serves as the basis for the regulations of 34 States and 2 Territories. In 14 States and 2 Territories it is in effect statewide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms to the standards for grade A milk as stated in the suggested ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication of the list is intended to encourage communities operating under the

This compilation is from the Division of Sanitary Engineering Services, Bureau of State Services, Public Health Service. The previous listing was published in Public Health Reports, March 1958, pp. 279-282. The rating method was described in Public Health Reports 53: 1386 (1938). Reprint No. 1970.

suggested ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they are more than 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

The rules for inclusion of a community on the honor roll are:

1. All ratings must be determined by the State milk sanitation authority in accordance with the Public Health Service rating method, which is based upon the grade A pasteurized milk and the grade A raw milk requirements of the Public Health Service milk ordinance. (A departure from the method described consists of computing the pasteurized milk rating by weighting the pasteurization plant rating twice that of the raw milk intended for pasteurization.)

2. No community will be included

on the list unless both its pasteurized milk and its retail raw milk ratings are 90 percent or more. Communities in which only raw milk is sold will be included if the retail raw milk rating is 90 percent or more.

3. The rating used will be the latest submitted to the Public Health Service, but no rating will be used which is more than 2 years old. (In order to promote continuous rigid enforcement rather than occasional "cleanup campaigns," it is suggested that, when the rating of a community on the list falls below 90 percent, no resurvey be made for at least 6 months. This will result in the removal of the community from the subsequent semiannual list.)

4. No community will be included on the list unless its milk supply is under an established program of official routine inspection and laboratory control provided by itself, the county, a milk control district, or the State. (In the absence of such an official program, there can be no assurance that only milk from sources rating 90 percent or more will be used continuously.)

5. The Public Health Service will make occasional check surveys of cities for which ratings of 90 percent or more have been reported by the State. (If the check rating is less than 90 percent, but not less than 85, the city will be removed from the 90-percent list after 6 months unless a resurvey submitted by the State during this probationary period shows a rating of 90 percent or more. If the check rating is less than 85 percent, the city will be removed from the list immediately. If the check rating is 90 percent or more, the city will be retained on the list for 2 years from the date of the check survey unless a subsequent rating during this period warrants its removal.)

Communities awarded milk sanitation ratings of 90 percent or more, July 1956-June 1958

NOTE: In these communities the pasteurized market milk shows a 90-percent or more compliance with the grade A pasteurized milk requirements, and the raw market milk shows a 90-percent or more

compliance with the grade A raw milk requirements, of the milk ordinance suggested by the United States Public Health Service.

Notice particularly the percentage pasteurized in the various communi-

ties listed. This percentage is an important factor to consider in estimating the safety of a city's milk supply. All milk should be pasteurized, either commercially or at home, before it is consumed.

publications

Trachoma Manual and Atlas. *PHS Publication No. 541; 1958; by Philip Thygeson; 42 pages; illustrated; 55 cents.*

The stages of trachoma, its clinical and laboratory diagnosis, and the criteria for differentiating trachoma from other follicular disease and either acute or chronic bacterial conjunctivitis are explained comprehensively in this medical handbook. Also discussed are the treatment procedures recommended for trachoma control campaigns. A series of photographs, 51 in black and white and 12 in color, show the gross appearance of trachoma and similar diseases in their various developmental stages.

Designed primarily for use by physicians and nurses in the Indian health program of the Public Health Service, the manual has potential value in trachomatous areas of other nations.

Dermatophytes—New methods in classification. *PHS Publication (un-numbered); 1957; 15 pages.*

It is recommended that physiological tests be used in conjunction with morphological studies for the accurate identification and classification of dermatophyte species.

A series of tests based on the nutritional requirements of certain dermatophyte species for vitamins and amino acids is described. These tests are particularly useful for identifying nonsporulating species such as *Trichophyton verrucosum*, *T. schoenleini*, and *T. concentricum*. They are also useful for identifying morphologically similar species such as *T. mentagrophytes* and *T. tonsurans* or morphologically atypical strains of any of the *Trichophyton* species.

Another physiological test described is based on the manner by which detached filaments of hair are attacked by dermatophyte species. This is particularly useful in

the separation of *T. mentagrophytes* and *T. rubrum* which attack hairs in vitro in different ways.

Free copies may be obtained from the Communicable Disease Center, Public Health Service, Atlanta 23, Ga.

The Research Attack Against Cerebral Palsy. *PHS Publication No. 552; 1958; 20 pages; 20 cents.*

The nature of cerebral palsy and the collaborative field investigation on this disorder being conducted through the National Institute of Neurological Diseases and Blindness are described in simple terms.

The booklet reviews some of the research findings of the recent past which may play an important role in the development of better methods of diagnosis, prevention, and treatment of cerebral palsy. It also contains an outline of the institute's grant programs as well as a concise view of the organization and growth of the institute as a component in the research mission of the National Institutes of Health.

The Dental Service Corporation—A new approach to dental care. *PHS Publication No. 570; 1958; 70 pages.*

Major points to consider in the formation, establishment, and operation of a nonprofit dental service corporation are reviewed.

One section of the pamphlet reports the historical development of the Washington State Dental Service Corporation, describes the corporate structure, and reviews its administration of a dental service program for the International Longshoremen's and Warehousemen's Union—Union Pacific Maritime Association Welfare Fund.

Another section covers general questions that planners of a dental service corporation must answer. Included are legal problems, tax re-

quirements, contract negotiations, administrative principles, premium determinations, and statistical system planning.

Summary of Health and Vital Statistics. *PHS Publication No. 600; 1958; 27 pages; 25 cents.*

Frequently requested recent and background statistical data pertaining to the United States are depicted in 24 tables and 12 charts with explanatory paragraphs. They cover the total population and the population by age as well as school enrollments, marriages and divorces, live births and fetal deaths, and illegitimate live births.

Infant and maternal mortality, total deaths and deaths by age, leading causes of death and leading causes of death by age groups, deaths from cancer and other malignant neoplasms, and deaths from accidents (including cause of injury) are tabulated by year, number, and rate.

The booklet also presents statistics on reported cases of and registered deaths caused by communicable diseases, cases of general illness from selected causes, and average remaining lifetime at specified ages for the entire population as well as by color and sex. A study of the beds available in civilian hospitals and skilled nursing homes is included.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared by other Federal agencies.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

A Controlled Evaluation of Mass Surveys for Tuberculosis and Heart Disease

PHILIP E. ENTERLINE, M.A., and BERNARD KORDAN, M.D.

A BASIC ASSUMPTION underlying mass casefinding programs is that those persons with disease who are detected are "better off" than they would have been had they not been detected. This assumption has never been completely tested, primarily because of the difficulty of obtaining a control group. A control group would consist of randomly selected persons participating in the casefinding program whose screening tests are positive but who are not advised of these results and are allowed to go on their way to be discovered by some other procedure, or possibly are never detected. Since casefinding programs are considered a service, a control group usually cannot be withheld deliberately, for moral and ethical reasons.

It recently became apparent that controls might be obtained for the evaluation of chest X-ray programs without raising questions of propriety or medical ethics. It has been known for some time that there are inconsistencies in interpreting chest photofluorograms (1-3); when two readers interpret a series of X-ray films, no matter how similar their training and orientation, some of the films will be selected as positive by one and negative by the other. This same phenomenon has been reported for

interpretations of electrocardiograms (4) and for examinations of children for tonsillectomy (5), and no doubt it could be observed in the application of many medical procedures.

In casefinding programs based on a single reading of photofluorograms, it is possible to identify by reading the films at a later date persons who appear positive but who were considered negative on the first reading. This group, who would not have received any benefits from the casefinding program since their apparent abnormality was not detected, would seem to constitute a control group for testing the assumption that persons whose disease is detected are better off than they would have been otherwise. The procedure would also identify a comparable group of persons considered positive on the initial reading and negative on the second reading. This group would have received whatever benefits casefinding has to offer and would constitute the study group.

Using this procedure for selecting study and control groups, we have examined the mortality experience of X-ray survey participants during a period of approximately 3½ years as an index of the benefits of this type of casefinding program. More than 200,000 photofluorograms taken in two large-scale, communitywide surveys, one in Los Angeles City and County, Calif., and the other in Dallas City and County, Tex., were re-read 3 to 5 years after the completion of the surveys. Sponsoring or participating in this study were the Texas and California State Health Departments, the Dallas and Los Angeles City Health Departments, the Dallas City and County and the Los Angeles

Mr. Enterline is chief statistician of the Heart Disease Control Program, Division of Special Health Services, Public Health Service. Dr. Kordan, now assistant clinical professor, radiology staff, University of Southern California School of Medicine, was during the time of this study chief of Radiology Services, Division of Special Health Services.

ECHOES from Public Health Reports

TYPHUS FEVER

THE EXPERIMENTAL TRANSMISSION OF ENDEMIC TYPHUS FEVER OF THE UNITED STATES BY THE RAT FLEA *XENOPSYLLA CHEOPIS*

By R. E. DYER, Surgeon, E. T. CEDER, Assistant Surgeon, R. D. LILLIE, A. RUMREICH, and L. F. BADGER, Passed Assistant Surgeons, United States Public Health Service

The incidence of endemic typhus fever in the United States, especially in the cities and towns of the southeastern States, has been brought to general attention in the past few years largely by the work of Maxcy (1). Whether endemic typhus of the United States is of European origin or represents an importation of Mexican tabardillo, or whether it is indigenous to the United States, is a matter of conjecture. Endemic typhus shows certain differences from the European, or epidemic, typhus, especially differences of an epidemiological nature. Epidemic typhus has its greatest prevalence in winter; it is associated with crowding; it is most prevalent in the lower strata of society; multiple cases in households, jails, and hospitals are common; and it has been shown repeatedly to be associated with lousiness.

In dis-

cheopis) has been

led out in the laboratory.

The foregoing evidence points to the rat flea (*X. cheopis*) as a common vector of endemic typhus from rat to rat and from rat to man.

that should not be correlated with variables under study.

The names of all persons whose films were considered positive by the radiologist were checked against the files of the death certificates maintained by the State health departments of California and Texas. In this way death rates were derived for the study and the control groups. Care was taken to provide the same information for each group in checking against files of death certificates. The mortality rates derived from this procedure covered approximately a 4½-year period for Los Angeles and a 2½-year period for Dallas.

Despite the fact that about the same percentages of films were probably positive on the first and second readings, the kinds of disease

in the study and control groups were, in the opinion of the radiologist, somewhat different. Since the probability of death within stated intervals varies from one disease to another, the mortality experience is presented separately for each suspected disease grouping.

Tuberculosis Suspects

A description of the films that the radiologist believed showed evidence of tuberculosis appears in table 2. The differences in the type and activity of tuberculosis in the two groups are important to the study insofar as they affect the mortality experience of persons with suspected tuberculous lesions.

For the Los Angeles films, the differences

County Tuberculosis Associations, the Los Angeles County X-ray Survey Foundation, and the Public Health Service.

The second readings of the X-ray films were done by physicians with training and orientation similar to that of the original readers. In neither instance were the readers qualified as radiologists, although they had received training in reading chest photofluorograms, with emphasis on the detection of tuberculosis.

The second readings were not in many instances done by the same physicians as those who did the first. Moreover, the conditions of the second readings were quite different from those of the first. The criteria used for classifying abnormalities on the two readings therefore probably differed. For this reason, one of us (B. K.), a radiologist, re-read all films called positive on only one of the two readings and prepared a detailed description of any abnormalities observed. He reviewed the films with the knowledge that one of two readers had considered them positive but without knowing whether it had been considered positive on the first or second reading.

In the final selection of films for the study and control groups, only the radiologist's interpretations were used. Relying on a single reader's observations provides some assurance that the same criteria were used to describe abnormalities for both groups. For example, it is possible that tuberculoma was defined somewhat differently by the first and second sets of readers. Having a third reader define tuberculoma for both the study and control

groups and using only his readings in comparing the two groups tend to minimize the effect of any differences in criteria. In addition, using only the films designated positive by the radiologist increases the likelihood that the abnormalities were truly pathological. The films called positive by the radiologist are, in fact, films that have been considered positive by two out of three readers.

The results of the first reading, the second reading, and the radiologist's review are shown in table 1. The first and second readings were made at about the same level of suspicion: 7,644 films (3,670+3,974) were considered positive at the time of the surveys, and 7,612 films (3,974+3,638) were considered positive on the second reading. The percentages of the positive films confirmed by the radiologist were about the same for the two readings, 87.5 for the first and 85.0 for the second.

The percentage confirmation for the second reading excludes 379 of the Los Angeles films not read by the radiologist. These films were not read because the names of the persons, essential for obtaining mortality information, were not legible on the photofluorograms. Since the entire file of records for 1,700,000 persons examined in this survey was in alphabetical order, it was virtually impossible to identify individuals from the film number (which was legible). Omission of these films should not bias the study results since the illegibility of the name was due to poor positioning of the survey records in the photo-identifier of the X-ray machines, a circumstance

Table 1. Results of re-reading 70 mm. photofluorograms taken in two communitywide chest X-ray programs

deaths is very small, the Los Angeles and Dallas data have been combined. The results for the combined groups appear to be approximated when each city-county group is considered separately.

In the age groups 45-64 and 65 and over, persons with X-ray evidence of tuberculosis who were given the "benefits" of casefinding had considerably lower death rates than those who were not. The difference in the age group 45-64 is statistically significant at the 5 percent level, using a one-tailed test of the hypothesis that the death rates were the same ($P=0.0274$). Whether the absence of deaths in the control

groups aged 15-44 has meaning or is due to the small number (295) of persons in these groups cannot be determined. The age-sex-race-adjusted death rate for all ages was 3.13 per 100 for the study group during the 2½- to 4½-year period, or about a third lower than the comparable rate of 4.73 per 100 for the control group. This difference is statistically significant at the 5 percent level (one-tailed test, $P=0.0262$).

Only one of the deaths observed among the tuberculosis suspects was coded to tuberculosis as the underlying cause (table 4). Two-thirds were ascribed to cardiovascular disease. Death rates for all causes were as high as or higher than the expected rate, based on death rates observed in the United States in 1950, in all age groups except 65 and over. Considering that all persons in this study were in sufficiently good health to participate in a communitywide chest X-ray program (suggesting that the expected deaths might be somewhat lower than for the United States as a whole) and that the procedures used in matching survey records with death certificates probably caused an understatement of the true death rates, the abnormalities discovered on the X-ray films undoubtedly had an effect on the mortality experience.

Any reduction in death rates among those suspected of having disease would, of course, be the result of medical and nursing care given them. In both Los Angeles and Dallas, followup of tuberculosis suspects was fairly complete. While data were not obtained spe-

were slight. Because of a slightly greater percentage of probably active lesions in the study group, its mortality rate would probably be somewhat higher than that of the control group. It is to be expected that persons with lesions detected in a casefinding survey would have a lower mortality rate (because of the medical and nursing care subsequently provided) than those whose lesions are not detected. Thus, the presence of a greater percentage of probably active lesions in the study group would tend to minimize the difference in mortality between these two groups, and would make conservative any estimates regarding benefits to tuberculous individuals resulting from discovery in chest X-ray surveys. It was decided, therefore, not to make adjustments for differences in the types of tuberculosis included in the study and control groups in Los Angeles.

For the same reason, no adjustment will be made for an even more important difference in types of abnormalities present in the study and control groups in Dallas. Here the difference was due almost entirely to the preponderance of tuberculomas in the study group, and the presence of these would tend to raise the death rate in this group.

The number of tuberculosis suspects and the number of deaths among them for the study and control groups are given in table 3. Adjusted death rates for broad age groups are shown in figure 1. The death rates within these broad age groups have been adjusted for age (10-year groupings), sex, and race (white and nonwhite) differences between the study and control groups. The adjustment was made by the direct method using a standard population consisting of the sum of the study and control group populations. Because the number of

about 15 percent lower than the comparable rate of 8.39 per 100 for the group of cardiovascular suspects overlooked in the survey. This difference is not statistically significant (one-tailed test, $P=0.1190$).

Again, any benefit to persons suspected of having a cardiovascular abnormality would presumably result from medical and nursing care. In Los Angeles, a followup program was established for cardiovascular suspects. Of those considered abnormal on a confirmatory

70 mm. X-ray, a diagnostic report was obtained by the health department on 78 percent (6). As with the tuberculosis suspects, data were not obtained specifically on the extent of followup and treatment given the study group used in this report. In Dallas, persons with abnormal photofluorograms were referred to their physicians for diagnosis and treatment, but no intensive followup was made by the health department to obtain diagnostic reports.

Other Diseases

There were too few cases in any other disease category to make analysis productive. There were, for example, only 411 photofluorograms on which the presence of a tumor was suspected by the radiologist. Of these, 231 were detected in the X-ray surveys but not on re-reading, and 7, or 3 percent, died during the followup period. Of 180 missed in the survey but detected on re-reading, 7, or about 4 percent, died.

Discussion

Theoretically, it was possible in this study to make the study and control groups identical (except for chance variation) by exact matching of all factors that could cause bias between the first and second film readings. These factors were the abnormalities appearing on the film itself and the person's age, sex, and race. Since no other information was available to

cifically on the extent of followup and treatment given the study group in this report, it is known that for all tuberculosis suspects referred, a final diagnosis was received by the health department on 90 percent in Los Angeles and on 81 percent in Dallas.

Cardiovascular Disease Suspects

The readings for the films in which the radiologist found evidence of a cardiovascular abnormality are shown in table 5. For films from Los Angeles there was a greater degree of heart enlargement in the control group than in the study group. Thus, a higher mortality rate might be expected in the control group even if there were no benefits derived from casefinding. This difference in degree of heart enlargement was associated with a difference in the age distribution of the Los Angeles population and

was compensated for by an age adjustment of the death rates.

Table 6 gives the number of cardiovascular suspects and the number of deaths for the study and control groups, and figure 2 shows death rates for broad age groups. As in figure 1, the rates have been adjusted for age, sex, and race differences in the two populations. Of the total 213 deaths observed none was due to tuberculosis; 156, or 75 percent, were due to cardiovascular-renal disease (table 7).

In each age group death rates were lower for those persons with suspected cardiovascular abnormalities given the benefits of casefinding than for the corresponding control group. None of the differences is statistically significant, however. The age-sex-race-adjusted death rate for all ages in the group of cardiovascular suspects given the benefits of discovery in a chest X-ray program was 7.16 per 100, or

Figure 2. Mortality experience for cardiovascular disease suspects: percentages adjusted for age-sex-race differences within age groupings.

A study group and a control group were constructed on the basis of a second reading several years later of 208,555 70 mm. photofluorograms taken in two communitywide chest X-ray surveys. This second reading made possible the identification of 3,638 persons considered negative at the time of the survey but positive when the films were re-read and 3,670 persons considered positive at the time of the survey and negative when the films were re-read. Of those considered negative at the time of the survey but positive on second reading, a reviewing radiologist considered 3,179 as positive (control group). Of those considered positive at the time of the survey but negative on second reading, he considered 2,772 as positive (study group). The mortality experience of these two groups was then compared.

For persons whose chest X-ray films showed evidence of tuberculosis, the death rate was about a third lower in the study group than in the control group ($P=0.0262$). For persons whose chest X-ray films showed evidence of cardiovascular disease, the death rate was about 15 percent lower in the study group than in the control group ($P=0.1190$).

These differences may be considered rough

estimates of the benefits of chest X-ray programs.

Mimeographed copies of a more detailed report of this study, including additional tables, are available from Philip E. Enterline, Heart Disease Control Program, Division of Special Health Services, Public Health Service.

New Division at National Institutes of Health

A Division of General Medical Sciences, headed by Dr. G. Halsey Hunt, has been formed at the Public Health Service's National Institutes of Health. The new division will administer research grants in the basic sciences and other fields, support training in the same fields through fellowships and training grants to colleges, and administer the Center for Aging Research. The first two functions have been transferred from the Division of Research Grants; the third from the National Heart Institute.

In line with these changes, the Division of Research Grants will study and evaluate all research grant and fellowship programs at the National Institutes of Health. It will continue to review, for all institutes and divisions, applications for grants and fellowship awards, and continue to process and pay grant and award funds. Dr. Ernest M. Allen will continue as chief of the Division of Research Grants.

the readers, no other factors could influence their decision on a particular film. Differences in age-sex-race distributions were compensated for by adjustment of the death rates, while effects of differences in criteria for classifying abnormalities among film readers were minimized by having the films reviewed independently and classified by a third reader.

Even with exact matching of the study and control groups, another factor that might affect the observed death rates is the mobility of the populations. Only files of death certificates in California and Texas were checked; hence, differences in death rates might have been due to a greater tendency for persons in the study group than for persons in the control group to die in another State. To check on this possibility, death rates observed during the first calendar year following the chest X-ray programs were compared for the study and control groups. Since death certificates for persons living in a State less than a year are allocated to the State of previous residence, the first year's mortality experience should be relatively free of bias due to departure from the State. It was found that differences in death rates during the first year were of about the same magnitude for the tuberculosis suspects and for the cardiovascular disease suspects as differences for the entire followup period. It would appear, therefore, that the lower death rate reported in the study group was not due to a larger out-migration of that group.

The fact that the control group was sent a negative report creates certain misgivings in making inferences as to the expected reduction in mortality for the tuberculosis suspects. While this report stated simply that the film "appeared satisfactory" and recommended an annual chest X-ray film, it may have deferred diagnosis and thus have worked to the disadvantage of the individual involved. There is no way of estimating the importance of this factor from the available data. If it exists, it may be offset by the imperfect matching for pathology between the study and control groups. As was noted above, this imperfect matching should have made the estimate of a third reduction in mortality conservative.

The problem of the negative notification is probably not so important for the cardiovas-

cular disease group, since the chest X-ray surveys used for this study were not generally publicized as casefinding devices for heart disease. Thus, receipt of a negative notification was not likely to be interpreted as absence of heart disease.

Whether estimates derived here of the extent to which individuals are better off as the result of participating in chest X-ray programs apply to all those identified in the programs or only to those persons with obscure or equivocal lesions is problematical. It might be argued that, if the benefits in case finding accrue largely because the disease found is in an early stage, and therefore is readily amenable to treatment, one would expect that persons with the very type of lesion with which this study is concerned would receive the greatest benefit.

This argument is probably more valid for cardiovascular disease than for tuberculosis. Under current treatment procedures for tuberculosis it is likely that nearly all clinical cases detected in a chest X-ray program benefit and that, in terms of averting death in the immediate future, persons with advanced disease benefit more than those with minimal disease.

From a statistical standpoint evidence of any benefit derived from the discovery of cardiovascular disease on chest X-ray surveys is weak. For tuberculosis, on the other hand, the results seem fairly conclusive. Possibly even larger differences in death rates would have been observed if it had been possible to reduce the study groups to the somewhat smaller number who actually received medical care and if appropriate control groups could have been identified for comparison. The study groups used here were, of course, diluted by some persons who were either considered essentially negative when a confirmatory film was taken or who were not kept under medical observation and treatment for other reasons.

Summary

A study was undertaken to test the assumption that persons with disease who are detected in casefinding programs are "better off" than they would have been had they not been detected.

radiation to health in general. The Assembly requested the Organization to cooperate with the International Atomic Energy Agency in health matters of mutual interest to avoid overlapping or duplication of effort.

Smallpox Eradication

The Director-General was asked to study the possibilities and practical implications of universal smallpox eradication, taking into account financial, administrative, and technical factors. He is to report his findings at the January 1959 meeting of the Organization's Executive Board. Governments throughout the world were urged to continue to fight smallpox with vaccination and revaccination campaigns, and medical scientists were called upon to work toward the production of improved vaccine resistant to the influence of temperature.

The U.S.S.R., which sponsored this resolution, announced that it was donating 25 million doses of smallpox vaccine to WHO; Cuba offered 2 million doses annually. The resolution proposed that WHO carry out preparatory work in 1958 to search for the best methods for worldwide eradication. It recommended mass vaccination in 1959-60 in countries where the principal endemic foci of smallpox exist, and additional vaccination and revaccination in 1961-62 of the population in which the disease persists.

Research

The Assembly requested that a special study be made of the role of WHO in research and of ways in which the Organization might assist more adequately in stimulating and coordinating research and developing research personnel. The United States Government is donating \$300,000 to set up studies of ways and means to promote research. Dr. Milton Eisenhower, personal representative of the President, made this offer in his address to the Tenth Anniversary Commemorative Session of the World Health Organization.

Sports Medicine

The Assembly called for studies to be made in collaboration with the International Federation of Sports Medicine, a nongovernmental agency which has official relations with WHO.

The studies will include the role of exercise and physical training in a constructive health program. The Netherlands and Canada opposed the action on the ground that the Organization's budget is too slender to divert funds from more urgent needs.

Poliomyelitis

A number of countries reported on the successful use of the Salk killed-virus vaccine. Some delegates complained that the high cost of the vaccine prevented its extensive popular use in their countries. The Assembly showed interest in extensive experiments underway in immunization through the use of orally administered, attenuated live-virus vaccine.

Survey of World Health

The Organization has compiled a comprehensive survey covering 1954-56 of health conditions throughout the world. It contains descriptions and appraisals of health programs completed or in progress in 157 countries and territories embracing 76 percent of the world's population. The Assembly asked that a second report with information covering 1957-60 be ready for submission to the 1962 World Health Assembly.

Voting Future Budgets

The Assembly decided that future Organization budgets must be approved by a two-thirds majority rather than a simple majority. During the debate the Director-General said that this idea had been considered and rejected by the framers of the WHO constitution. He saw in this step the danger of creating a precedent, changing an essentially organizational matter merely by altering the rules of procedure. The prevailing view was that a two-thirds majority would strengthen the hands of representatives when they seek budget funds for the Organization in their respective countries.

Elections

The Assembly elected as president for 1 year Dr. Leroy E. Burney, Surgeon General of the Public Health Service (United States); as vice presidents, Dr. J. Anouti, Director-General, Ministry of Public Health (Lebanon),

We look to the World Health Organization with confidence as a proven instrument through which the nations and the peoples of the world can combine their efforts, in friendship, toward the building of true peace.

—Dwight D. Eisenhower.

Eleventh World Health Assembly

The Eleventh World Health Assembly, meeting in Minneapolis, Minn., May 28–June 13, 1958, adopted a 1959 public health program of 800 projects, touching nearly every country and territory in the world. Delegates of the 88 member states of the World Health Organization voted a budget of \$14,287,600 to carry out this work.

Major Assembly actions provided for the extension and intensification of the global eradication of malaria, a comprehensive WHO undertaking in the health aspects of atomic energy, measures for the worldwide eradication of smallpox, greater emphasis on research, and studies in sports medicine.

Malaria Eradication

Delegates reported that malaria eradication is being extended and is underway in 76 countries, containing one-third of the world population. However, because much greater international financing is essential to the success of this campaign, the Assembly authorized the Director-General to seek funds from foundations, industry, labor organizations, institutions, and individuals, as well as governments. WHO's Malaria Eradication Special Account contains only a little more than \$5 million, sufficient only for 1958 activities. UNICEF, which con-

tributed \$8 million to this effort in 1957 and in 1958 and has earmarked a similar amount for 1959, will halve its contribution in 1960.

The delegate of the Soviet Union announced that his government would donate 1,000 tons of DDT to WHO and could make available technically qualified experts to promote eradication of malaria. The Assembly requested the Organization to extend research, particularly in the phenomenon of mosquito resistance to insecticides.

Health Aspects of Atomic Energy

A resolution, unanimously approved by the Assembly, directs the Director-General to investigate methods in dealing with health hazards implicit in the peaceful uses of atomic energy. He is to report especially on methods for ascertaining and recording the exposure of individuals to all radiation sources, for determining the relationship between radiation dosage and congenital defects, and for notifying public health authorities of congenital defects which could be caused by radiation.

The resolution also opens the way for the Director-General to aid underdeveloped countries in the use of radionuclides in medicine, and for a study of the effect of radiation on human heredity and of the relationship of

The First 12 Years of WHO

THOMAS PARRAN, M.D., LL.D., Sc.D., Dr.P.H.

At the Eleventh World Health Assembly Dr. Thomas Parran received the Leon Bernard Foundation Prize for outstanding achievement in social medicine. The award, established by the League of Nations and administered by WHO, was presented to him in recognition of his contributions to public health in the United States, particularly control programs for venereal disease, tuberculosis, and cancer, and Federal assistance to States for hospital planning and construction.

Dr. Parran, first dean of the Graduate School of Public Health, University of Pittsburgh, and Surgeon General of the Public Health Service from 1936 to 1948, has recently assumed direction of the Avalon Foundation.

Other recipients of the prize have been Prof. René Sand (Belgium), Prof. C.-E. A. Winslow (United States), Dr. Johannes Frandsen (Denmark), Prof. Jacques Parisot (France), Andrija Stampar (Yugoslavia), and Prof. Marcin Kacprzak (Poland).

NO GREATER HONOR can come to anyone in public health and social medicine than to receive the Leon Bernard Foundation award. This is particularly true when one reviews the role of honor of those who have earlier received the award and when one considers that it is voted by the World Health Assembly, representing the world health leaders of our time.

I accept the award with deep gratitude and humility.

My first contact with international health affairs was in 1926, when I was selected as one of 12 young medical officers from 11 different countries to engage in a study tour of Denmark for some months, following which we spent a week in Geneva to report upon our experiences and to learn about the work of the health section of the League of Nations. For me, this was a great educational experience. Since then, I have continued to learn about

international health in many capacities. Each of these experiences has broadened my understanding of the needs for, and the possibilities of, international cooperation in the field of health and of technical assistance generally.

In July 1946, at the signing of the constitution of the World Health Organization, I said that we were "signing a Magna Carta for health which will bring into being a World Health Organization unique in its scope, authority, and functions." I ventured to forecast the successive steps which WHO would take during the years ahead. These included "help in healing the wounds of war and eliminating the ancient human plagues, such as malaria and cholera, tuberculosis and syphilis. Prevention of disease is a first objective.

"To attain freedom from want of food is another goal which we may hope to reach by pooling our nutritional knowledge with the food and agricultural efforts of the United Nations.

"A next step toward world health is the positive improvement of health. Higher levels of physical development, a longer, more productive, more vigorous life span will be sought and attained.

"But prevention, treatment, and control of disease should be supplemented by intensive research in the laboratory, at the bedside, and in the field to push back the frontiers of the unknown in the health sciences."

Also, I said, "In our Magna Carta for health, we have ventured to declare that we have a contribution to make to the central world problem of today, which is to help man learn to live harmoniously with his fellow man. In making this proposition, I for one believe that health science must share the task with religion and education."

I concluded by saying, "The World Health Organization is, therefore, a collective instru-

Three Surgeons General of the Public Health Service, two past and the incumbent, were among delegates to WHO's Tenth Anniversary Commemorative Session in Minneapolis, May 26-28, 1958. From left to right: Dr. Leonard A. Scheele, Dr. Thomas Parran, and Dr. Leroy E. Burney. Dr. Burney presided over the Eleventh World

Health Assembly, which met May 28-June 13, 1958. Dr. Scheele is a past president of the Assembly, and Dr. Parran was one of the signers of the original charter of the World Health Organization. The World Health Organization met in this country at the invitation of the United States, following appropriate action by Congress.

Dr. A Sauter, Director of Public Health (Switzerland), and Dr. Tran Vy, Health Minister (Vietnam); as chairman of the Committee on Program and Budget, Prof. N. N. Pesonen, Director-General of the State Medical Board (Finland); and as chairman of the Committee on Administration, Finance and Legal Matters, M. S. Khanachet, member of the Saudi Arabian Legation in Bonn.

Executive Board

The 18-member Executive Board as constituted after elections by the Assembly includes Afghanistan, Australia, Brazil, Canada, Federal Republic of Germany, France, Guatemala, India, Iran, Italy, Liberia, Mexico, Tunisia, U.S.R.E., United Arab Republic, United States of America, United Kingdom, and Vietnam.

Membership and Finances

Membership in the World Health Organization has grown from 26 countries in 1948 to 88 at present. Two new member states are the Federation of Malaya and the United Arab Republic. Czechoslovakia resumed active status in the Organization in 1958.

In addition to the \$14,287,600 voted for the 1959 budget, WHO received a supplemental \$6 million of United Nations Technical Assistance funds, and nearly \$9 million was contributed to the special malaria eradication funds of the Organization and its regional representative, the Pan American Sanitary Bureau. The 1957 collection of contributions from active members reached 97.08 percent, a record in the history of WHO, according to the External Auditor's Report.

with emergingly known genetic behavior, and disease agents of grave seriousness. Who has jurisdiction here? Is it the physical scientist, the biologist, or the physician? Clearly, we need to submerge the old distinctions and preserve the interrelations and wholeness of nature.

There has been a long transition from the primitive ritual of the medicine man to today's medicine of the sciences. The expansion of medical knowledge and teaching in recent years has been dominated by the scientific discipline of medicine itself and by segments of knowledge drawn from other sciences, so that today biological and natural sciences have become the very matrix of medical thought. Physics, chemistry, and biology are its language and tools.

The past century has been called the era of the biological and the physical scientist, but today we may be entering the century of the psychological or of the physiological-sociological-anthropological man. Perhaps in the next century the first half of this one will be noted as the period in which society moved away from its preoccupation with man solely as an economic creature.

Public health has been termed "an applied technology resting upon the joint pillars of natural science and social sciences." During the past century the natural science pillar has been greatly strengthened, but until both the pillars are strong the arch of public health will not be firm. Now, consideration also is being given to the social aspect of the environment, especially as it interacts with biological and physical stresses. Since stress effects are both psychological and physiological, emphasis must be given to fuller understanding of psychological factors in stress and disease reactions.

My colleague, Dr. Robert E. Olson, draws attention to the problems facing public health: "The biochemist who studies the kinetics of a purified enzyme system has only a few variables to control; the physiologist who studies the metabolism of an intact organ in an animal has many more to consider; the physician who studies a disease process in an intact human animal has even more parameters to correlate and attempt to control in the diagnosis and treatment of his patient. But the public health scientist who is studying the behavior of popu-

lations is dealing with an infinitely complex situation, to which, in many instances, only statistical solutions are possible."

In the past, certain factors known to affect public health adversely could be engineered out of the physical environment. Today, there is needed a revealing analysis of the social environment which blocks the way of abundant public health. Most of the degenerative diseases, which constitute our major health problems, have psychosocial components. The so-called psychosomatic diseases such as hypertension, peptic ulcer, rheumatoid arthritis, thyrotoxicosis, and schizophrenia have direct psychiatric determinants; others such as obesity, alcoholism, and coronary artery diseases have at least indirect relations to sociocultural patterns of diet, anxiety reduction, and stress.

Public health needs to be increasingly concerned both in research and in teaching with a comprehensive ecologic approach to problems of disease and of health if we are to be successful in understanding better the degenerative diseases and mental illnesses. The clinician must expand his horizon to include the role of the family and the community in relation to the disease problem at hand. By the same token, the public health scientist must not be content solely with statistical solutions and epidemiological inferences in his analysis of these knotty problems. The meeting ground is the interdisciplinary team play of a group from many fields of science, in sympathetic agreement with each other, and with access to the experimental laboratory, the patient, the family and the community, if need be, in the pursuit of the problem under study.

Those of us who use epidemiological and biostatistical methods primarily should remember that acute clinical observation may supply the clue, even though it be made only on one patient. Claude Bernard, French physiologist, once said, "I do not reject the use of statistics, but I condemn not trying to go beyond them" (quoted in the *New York Times*, E-9, April 13, 1958).

It is recognized that epidemiology does not deal solely with infectious diseases. It was through epidemiological investigations that the nature of pellagra and of goiter was discovered. There is an epidemiology of suicides, of acci-

ment which will promote physical and mental vigor, prevent and control disease, expand scientific health knowledge, and contribute to the harmony of human relations. In short, it is a powerful instrument forged for peace."

The goals set for the World Health Organization represented the highest aspirations of the human spirit. Few of us believed that they could be reached fully and in a short time span; but we should never lose sight of them. It is a source of great satisfaction that we have moved "ten steps forward." They have been 10 important steps which might be described more accurately as 10 times 10. That such substantial progress has been made is all the more remarkable when we consider the continued unsettled conditions in world affairs during these past 12 years. For what has been accomplished, primary credit is due to the competent leadership of the first two Directors-General, Dr. G. Brock Chisholm and Dr. M. G. Candau. Credit goes also to the staff in Geneva and in the regional offices, as well as to the delegates to the 11 annual health assemblies and the members of the Executive Board.

In retrospect, I think that a sound decision was taken at the First World Health Assembly to limit the initial objectives and programs to urgent problems of worldwide importance. These were control of malaria and tuberculosis as well as important acute communicable diseases, the improvement of nutrition, measures to promote maternal and child health, and sanitation of the environment.

It is gratifying that the initial programs have been intensified through a somewhat larger central budget and through the Expanded Programme of Technical Assistance, and that the substantial resources of UNICEF have been joined in promoting some of the important objectives of the World Health Organization.

From the outset, education and training have played important roles—8,000 WHO fellowships attest to this—and the more recent concern both of the United Nations and the World Health Organization with atomic energy in relation to health recognizes the importance of this new factor in man's environment.

Because of my preoccupation with the advancement of the health sciences through

research and the training of future workers, both in the general field and in a number of its subdivisions, what I have to say will naturally center about this experience.

In May 1957, we held a series of seminars in Pittsburgh as a part of the ceremonies inaugurating our new chancellor and dedicating our new School of Public Health building. The themes were "Contributions of the Sciences to Public Health in the Years Ahead" and "Fusion of the Sciences for Better Health." I shall try to summarize some of the conclusions.

Viewing the sciences in historic perspective, one can detect periodicity. There have been periods of fusion and the reverse, a disintegration of effort. In the earliest period, the natural philosophers were the universal scientists, exploring all of life in order to gain greater knowledge of its meaning. (In the future, as in the past, the philosophers will contribute to our understanding of life, of natural laws, and of the universe.)

In due course, it became possible to study one or another aspect of life and living creatures. This led to specialization by medical research and medical teaching which burgeoned until a specialist came to be defined as a person who knows more and more about less and less. There are signs that this trend is being reversed—that a scientist needs to have more than one skill under one skull—and that future progress lies through a fused spectrum of scientific knowledge. This trend, apparent in medical and public health practice, is to see man and his environment as a whole and especially to interpret the dynamic interactions in these man-environment interrelationships. In short, human ecology.

During recent years the earlier distinction between public health and medicine has been blurred; there has also been a great decrease in the earlier distinction between physical and biological science so that at present there is no boundary within the biological sciences which the physical sciences cannot usefully pass. In this process of infiltration, there is the resulting integration of all biological sciences into a continuous and more meaningful whole. The viruses are a case in point. They are inert chemicals under certain circumstances; under other circumstances, reproducing organisms

for research and for the training of individuals to deal with them. The Graduate School of Public Health at Pittsburgh is pioneering in such a program of research and in the training of new types of specialists who can combine knowledge of the traditional health sciences with the newer knowledge of nuclear technology. This expanded area of health training will be invaluable in maintaining the health of mankind as we enter nuclear competition.

While never losing sight of its long-range goals, the World Health Organization in every situation must build upon what now exists in every country and region; each step forward must be practical in the light of the limitations imposed by traditions, customs, and resources.

It is gratifying to note the trend in many countries to seek the Organization's help in working out long-term plans for a continuing development of their own health services, and the growing willingness of nations to engage in joint action with their neighbors to solve common problems.

In the Director-General's Annual Report for 1955, the importance of strengthening the national health services is stressed. There are indications that nations, large and small, are becoming increasingly aware of the value of self-help in taking responsibility for the long-range development of their own health services, and that they seek aid mainly in three directions: supplies to be used in the worldwide struggle against communicable disease, the strengthening of the services already established, and the raising of standards of education and training of all types of health workers.

Even more attention needs to be given by the World Health Organization and every member state to the collection of more accurate and more comparable health statistics. Without them the course of public health cannot be charted wisely.

I have referred to the worldwide population explosion and the need for health agencies at all levels to be concerned about it, to seek to understand better these complex phenomena, and within religious and cultural contexts to devise programs of research, education, and action to deal better with them.

There are two great drains upon the re-

sources, the manpower, and the accumulation of capital in most countries which detract from human health and well-being: expenditures to provide housing, food, clothing, and other items required for normal living by the too rapidly increasing population, and expenditures for war or the prevention of war, defense.

What a different world we could have if some of these expenditures could be diverted to the better cultivation and development of the human capital, the human resources, in each country. Health, education, recreation, and nutrition are obvious needs. Should not most of these savings be diverted to programs in each country to improve standards of health and well-being, and some funds be made available to the World Health Organization and other specialized agencies?

Specifically, I propose that all member states of the Organization, in addition to their regular contributions, take 2 percent from their annual appropriations for military purposes and use it as an extra contribution to the Expanded Programme of Technical Assistance of the United Nations, in which the World Health Organization should have a substantial share.

With such funds and the sentiment behind them, malaria eradication would be speeded up; smallpox, tuberculosis, syphilis, and yaws would be next to go. In fact, all of the ancient plagues could be conquered within a measurable number of decades. Then WHO could turn its energies more fully to improving nutrition, to promoting physical and mental vigor, to expanding scientific health knowledge, and finally to the most difficult task of all—the improved harmony of human relations.

The substance of the comments in this address was published in California Medicine 88:411-416, June 1958.

dents, of cancer, and of atherosclerosis. Some beginnings have been made in the epidemiology of mental health and disease. I have pointed out elsewhere (1) the need for intensifying greatly these types of epidemiological studies.

When we have parallel biochemical studies, we may, by the epidemiological method, identify disease-prone individuals in a population before they become sick. Once these individuals with biochemical differences can be identified, it may be possible to control internal factors as well as the external environments and thus retard the progression of disease; almost certainly, there are such psychosocial and nutritional factors. Such knowledge may be to the prevention of degenerative disease what immunization and good sanitary engineering have been to the prevention of communicable diseases.

It is agreed that the behavioral and the biological or biochemical aspects of man are not separated by an impassable gulf.

But in our preoccupation with new and complex problems, public health workers should continue their emphasis upon traditional bases for action. We need also to apply to the newer problems the principles which have been learned from the past.

As one looks back, man has been concerned over the centuries with getting enough food to meet his metabolic needs and controlling his microbiological environments. Neither objective is met for most of the world's people. The continued growth of population, estimated at 1.6 percent per year, may continue to outrun increased food production. Consequently, public health must be concerned with problems of natality as well as with those of mortality.

The economy of scarcity has been superseded by overabundance in the United States and other western nations. Hence, we are concerned with metabolic disorders, obesity, alcoholism, and effects of smoking, which are disorders of excess rather than deficiency. Even the concept of stress as a cause of mental ill health connotes excess—the impact of more challenges than the organism is able to bear. Sir Geoffrey Vickers says, "Our hazards from excess range from excessive nuclear radiation through excessive smoking, to the excessive consumption of ice cream—products which

have in common the fact that our superabundance is our own desiring" (2).

Recently, George J. Stolnitz has reported on "A Century of International Mortality Trends." He concludes that the rise in life expectancy over the past century probably has been more far-reaching than the gains of the previous 2,000 years; that the increases in western countries in the expectation of life at birth since 1890 have been more than double the gains over the preceding half-century; and that many of the mortality trends in western life changes are "unrepeatable phenomena." It is irrefutable that major gains of the future in lifesaving must come in the ages beyond 60. In documenting this point, Stolnitz calculates that if all mortality before age 45 were eliminated, the resulting gains would be no more than half of the rises in life expectancy at birth since the beginning of this century (3).

Each new breakthrough in the health sciences and each shift in living patterns will produce additional tasks for the World Health Organization and for national health services. Certainly, we are agreed that additional responsibilities have been produced by urbanization, by industrialization, by the major threats arising from air pollution, and even from the density of automobiles on the highways. Yet none of the serious problems evoked has been solved.

Added to the familiar environmental hazards is that new factor in man's environment, nuclear fission, and its use for the production of power. The known supply of fossil fuels is inadequate. In the absence of practical methods for harnessing solar energy and for unraveling the secrets of photosynthesis, nuclear power is being developed on a huge scale. This will increase at an ever-accelerating pace with many nations getting into the act but having too little comprehension of the dangers.

The disposition of radioactive garbage poses a whole series of enigmas not yet solved by the nations most technically advanced in nuclear fission. Such problems will confront us increasingly. We must develop the organization and the personnel and, most important of all, acquire the knowledge with which to cope with these problems.

Radiation biology now offers many new fields

Intensive clinical and epidemiological studies strongly pointed to a common source of acute Salmonella reading infection occurring in more than 300 persons in widely separated areas of the United States during a 12-month period. However, no common source of infection could be identified.

Widespread Salmonella reading Infection of Undetermined Origin

ROBERT H. DRACHMAN, M.D., NORMAN J. PETERSEN, B.S., JOHN R. BORING III, M.S., and
FRED J. PAYNE, M.D.

DURING the period from September 1956 through early September 1957, 325 acute sporadic cases and 3 outbreaks of salmonellosis due to *Salmonella reading* occurred in the United States. Previous to this time *S. reading* had been rarely encountered in typing laboratories. Although the epidemiological picture strongly pointed to a common source of infection, none could be identified in spite of intensive study. This "outbreak" is an example of a phenomenon periodically noted by *Salmonella* typing laboratories when, within a few weeks, a relatively large number of cultures are received containing a serotype which has

previously been encountered only rarely. This phenomenon is seldom explained except when circumscribed outbreaks of salmonellosis are clearly involved. The salient features of the 1956-57 "outbreak" follow.

The "Salmonellosis" Outbreak

In late March of 1957, Dr. Frederick H. Wentworth of the bureau of communicable diseases, Ohio Department of Health, reported 13 isolations of *S. reading*, indicating a sharp increase of this type of *Salmonella* compared with the previous experience of the health department. About half of the isolations were from blood cultures, and all came from children in widely separated areas of the State. Inquiries to Dr. Philip R. Edwards, chief of the Enteric Bacteriology Laboratory, Communicable Disease Center, and to other *Salmonella* typing centers throughout the country revealed a similar recent increase in *S. reading* isolations. Accordingly, a plan for national surveillance was instituted. A summary of available data was distributed to State health officers, epidemiologists, and laboratory directors. Requests were made for the prompt submission of epidemiological data on all instances of *S. reading* infection, with particular attention to pos-

The authors, at the time of the study, were all with the Enteric Disease Investigations Unit, Epidemiology Branch, Communicable Disease Center, Public Health Service, Atlanta, Ga. Dr. Drachman is currently chief of the unit. Mr. Petersen, sanitary engineer epidemiologist, and Dr. Payne, epidemiologist, former chief of the unit, are now with the Phoenix Field Station, Phoenix, Ariz., and Mr. Boring, bacteriologist, is with the department of bacteriology, University of Florida, Gainesville.

The paper was presented in part before the epidemiology section of the American Public Health Association at its annual meeting in Cleveland, Ohio, November 14, 1957.

Plague organisms from a mouse spleen smear, which has been stained with fluorescent antibody. On the left side, with visible light, the viewer sees a great deal of material from which it is exceedingly difficult to separate the plague organism; on the right side, with ultraviolet light, only the plague bacteria show up.

FLUORESCENT ANTIBODY TECHNIQUES

Fluorescent antibody techniques for rapid laboratory identification of pathogens, and of antibodies produced in man by these microorganisms, are under development at the Communicable Disease Center of the Public Health Service. These new diagnostic methods, which use a fluorescein dye to "light up" individual disease organisms, promise one day to enable the physician to make an accurate diagnosis of certain communicable diseases within minutes after the patient comes to his office.

In describing these methods, Dr. R. J. Anderson, chief of the Communicable Disease Center, explained that the first step is to "label" with a fluorescent dye a globulin solution containing antibodies specific to certain organisms. When dried smears made from specimens are covered with the tagged antibody solution and observed through a microscope under ultraviolet light, any homologous organisms or their products will fluoresce. The process takes a few hours or less, whereas other methods take 2 or 3 days or even sometimes weeks.

A corollary method detects antibodies rather than the actual pathogenic organisms at stages of infection when the organism is not available for identification.

These quick, relatively simple, versatile laboratory procedures may possibly apply to the identification of pathogens in all kinds of specimens either from the individual patient or from the environment. As the somewhat laborious matter of adapting them to use with different bacteria and viruses and with their respective antibodies is completed, they are expected to take an important place in the work of laboratories all over the country.

Before these procedures can come into general use, several practical problems will have to be solved, Dr. Anderson indicated. Microscopes equipped with the appropriate ultraviolet light will have to be made available, and technicians will have to be trained to use the new methods. Tight budgets also may delay the use of the fluorescent antibody techniques in many localities.

Intensive clinical and epidemiological studies strongly pointed to a common source of acute Salmonella reading infection occurring in more than 300 persons in widely separated areas of the United States during a 12-month period. However, no common source of infection could be identified.

The paper was presented in part before the epidemiology section of the American Public Health Association at its annual meeting in Cleveland, Ohio, November 14, 1957.

Month of onset of 283 cases of salmonellosis due to *Salmonella* reading, exclusive of asymptomatic carriers and secondary cases.

¹ Data provided by Dr. Philip R. Edwards, chief, Enteric Bacteriology Laboratory, Communicable Disease Center, Public Health Service, Atlanta, Ga.

sible sources of infection. A standard food history form was prepared and circulated. Several Epidemic Intelligence Service officers worked in cooperation with 11 State health departments in obtaining field data.

The chart shows the month of onset for 283 reported cases of salmonellosis due to *S. reading* for which such information was available. A total of 392 isolations of this type representing repeat cultures, family contacts, and outbreaks was reported during the same period. An early increase in cases is noted in October of 1956 with a peak in February of 1957 and a decline to previous incidence by May of that year.

Table 1 shows the distribution of the reported cases by State and month of onset. In this table, family and other group outbreaks are counted as single episodes. Cases appeared simultaneously in several widely separated areas of the country. No progression of *S. reading* isolations from one geographic area

to another is apparent. However, most positive isolations were reported from the northern tier of States. In view of the wide variation in the degree of utilization of laboratory facilities in various areas, no attempt is made to calculate attack rates.

The age distribution of 248 patients with salmonellosis due to *S. reading* for whom age data were given is presented in table 2. Cases are concentrated among infants and children, with 18 percent of the total number under 1 year of age and 11 percent under 6 months. This grouping agrees with the tabulation by MacCready and co-workers of ages for 2,092 patients with *Salmonella* infections in general (1).

Clinical and Laboratory Data

Detailed clinical and laboratory data were obtained for 69 patients, and henceforth these will be called the study group. The information is summarized in tables 3-7. Hospital records of 20 patients were abstracted, and health

department records and personal interview data were available for all 69 patients. These patients are probably not representative of persons ill with salmonellosis due to *S. reading* but for prejudicial reasons happened to have been cultured during a bout of gastroenteritis. It is striking that the vast majority of homes visited revealed families of above average income. However, this was merely an impression, and no attempt was made to evaluate the economic status of the families interviewed.

The median age of the study group was 3 years, with a range of from 1 week to 64 years

(table 3). In this respect the lower age range of the study group approximated the age distribution of the previously described group of 248 patients. More than half of the patients were hospitalized, with a median hospital stay of 8 days (table 3). Patients were reported to have been severely ill in 53 percent of the cases, 27 percent were moderately ill, and 20 percent were mildly ill (table 4). These were subjective impressions by patients and were not quantitated objectively. Symptoms persisted for a median of 7 days although the time was some-

what longer in the group less than 1 year of age.

Leukocyte counts were available for only 20 patients and are summarized also in table 4. The counts ranged from 3,150 to 20,000 per cubic millimeter with the median values tending to decrease with increasing age. A slight to moderate lymphocytosis is reflected in the differential counts, with the expected higher lymphocyte counts in the younger age group

All study group patients were, of course, positive for *S. reading* by stool culture. Blood cultures were made for only 8 patients. Of these, 7 cultures yielded *S. reading*. No diarrhea was reported for 4 of these 7 patients.

Elevated temperatures were reported for 94 percent of the 65 patients for whom this information was given. The median of highest recorded values was 103.2° F. (table 5). Febrile convulsions occurred in only one child, a 2-year-old girl. Diarrhea was considered present only when 5 or more stools occurred in 1 day.

Table 6 summarizes the data regarding secondary episodes of gastroenteritis in 65 exposed families. Attack rates calculated by family size revealed similar rates in all families.

Local health department personnel obtained stool cultures from family contacts in 33 households harboring index cases. *S. reading* was isolated from specimens obtained in 55 percent of these households (table 7). Mothers were positive four times more frequently than were fathers. As noted in table 6, only 5, or 23 percent, of the 22 *S. reading* positive children reported any gastrointestinal illness. However, *S. reading* was found in cultures from one-third of the children ill with gastroenteritis who were family contacts.

Among the index cases, other *Salmonella* types in addition to *S. reading* were isolated from 9 patients. These types included *S. muenchen* isolated from 3 patients, *S. paratyphi* B, from 2 patients, and *S. manhattan*, *S.*

typhimurium, *S. montevideo*, and *S. siegburg* from 1 patient each. Cultures of family contacts revealed 6 individuals with other *Salmonella* types: *S. typhimurium*, *S. bareilly*, *S. sandiego*, *S. muenchen*, and *S. oranienburg* were each isolated from one patient, and another patient was found positive for both *S. muenchen* and *S. oranienburg*. Admittedly, the usual press of laboratory work does not permit the serotyping of any large number of colonies from a single specimen. Conse-

quently, the above is only a suggestion of what other *Salmonella* types may have been present in these patients and contacts.

Food History

A summary of the responses to questions on food consumption is given in table 8. No comparable data were collected from an unaffected control population. Some difficulty was anticipated in obtaining accurate food histories since the average time lapse between the date

of onset of gastroenteritis and that of the interview was 8 weeks. Recall of specific foods eaten prior to onset of the illness, therefore, appeared to be an unrealistic expectation. Consequently, an enumeration of the family's usual food intake was requested. Families were looked upon as a unit in terms of foods consumed since transfer of *Salmonella* among family members may have easily occurred in many instances.

Special emphasis was placed on a search for some single consistently mentioned brand name of a nationally distributed food or food product. None was found frequently enough to implicate it as the presumed common vehicle.

¹ Multiple brand names mentioned for all items.

² Other than cottage cheese.

Many different brand names were mentioned for the most frequently reported foods listed in table 8. Foods previously implicated in extensive outbreaks of salmonellosis, such as canned meats (2) or dried eggs (3, 4), were not commonly used in these families. Frozen meat items requiring only warming before use were also infrequently encountered. The possibility remains, of course, that the crucial food item may not have been included among those on the food questionnaire.

Families were also questioned about the presence of pets in the home. Only 8 families of the 69 questioned owned either a cat, a dog, or a parakeet.

In view of these negative findings, an alternative hypothesis was employed which suggested that some common additive to a frequently mentioned food might be the sought-after common vehicle of infection. This possibility was investigated by means of a study of ice cream which had been mentioned by 97 percent of the families interviewed. A careful enumeration of the ingredients used in several of the ice cream brands consumed failed to reveal any single nationally distributed common additive. Other commonly used foods, such as mayonnaise or salad dressing and peanut butter

(table 8), were disqualified as potential *Salmonella* vehicles because of the failure of these organisms to survive in such media (5, 6). Chicken was consumed by 99 percent of families questioned. However, it was not apparent how birds from many different sources, including small home-fed flocks, could all be infected with a similar, previously rare *Salmonella* type.

In view of the large number of children affected, special attention was given to foods which might be common to this age group. Despite several specific questions included in the food questionnaire, no common brand name baby food, vitamin preparation, or formula mixture was encountered.

Discussion

As an estimate of the magnitude of the problem, data on the number of isolations of *S. reading* in previous years were provided by Dr. Philip R. Edwards, who reported that, during the 8-year period from 1948 through January 1956, only 24 cultures of *S. reading* were identified among approximately 18,000 cultures received. In contrast, 125 isolates representing individual cases were identified at the Communicable Disease Center as *S. reading* during the 16-month period from May 1956 through early September 1957. Of particular interest was the apparent concentration of cases in this country, with few cases reported elsewhere. Inquiries to *Salmonella* typing centers in Canada, England, Northern France, West Germany, and the Netherlands failed to reveal any recent marked increase of *S. reading* isolations in these areas corresponding in time with the peak of cases in this country. However, in 1952 the Netherlands had experienced a sharp rise in *S. reading* cases from an average of 2 to 4 per year to 51 isolations that year. No explanation of this sudden increase and equally sharp decline was available.

Isolations From Animals

As a further attempt at solution of the problem, additional instances of recent *S. reading* isolations, other than from humans, were looked for. State veterinary public health officers were contacted by Dr. James H. Steele, chief, Veteri-

Data on the incidence of *Salmonella reading* isolations in their respective countries were provided by: Dr. E. T. Bynoe, Laboratory of Hygiene, Department of National Health and Welfare, Ottawa, Canada; Dr. Joan Taylor, *Salmonella* Reference Laboratory, Central Public Health Laboratory, Colindale, London, England; Dr. R. Buttiaux, Institut Pasteur de Lille, Centre d'Enseignement et Recherches de Bactériologie Alimentaire, Lille, France; Dr. H. P. R. Seeliger, *Salmonella-Zentrale*, Hygiene-Institut der Universität Bonn, Bonn, Germany; Dr. A. Clarenburg, Rijks Instituut Voor de Volksgezondheid, Utrecht, Netherlands.

nary Public Health Section, Communicable Disease Center, and 9 recent poultry outbreaks of clinically evident salmonellosis due to *S. reading* were reported. The chart shows the few July and August 1956 poultry isolations which preceded the sharp rise in human cases. Since the virulence of *Salmonella* types varies considerably in chicks (7), the organism may be carried with minimum symptoms, and *S. reading* might have been extensively distributed among poultry despite the few reported isolations. Galton and associates (8) have demonstrated the frequency with which salmonellae may be detected in poultry processing plants. If fowl were contaminated with salmonellae, then some nationwide means of infecting poultry would have to be postulated. Feeds might serve this function particularly since a constituent of many poultry feeds is frequently contaminated with *Salmonella*.

Fishmeal imported into West Germany, where much of it is used in animal feeds, was frequently found to be contaminated with *Salmonella* according to Rohde and Bischoff (9) and Adam (10). Furthermore, the isolation of the new serotype *Salmonella blockley* from fishmeal in 1955 occurred almost simultaneously with the occurrence of the first human cases of *S. blockley* infection (11, 12). A relationship between the two through the medium of infected animals was inferred. During 1957, according to a personal communication from Dr. H. P. R. Seeliger, *S. reading* was isolated in West Germany from imported fishmeal and was also found to be the etiological

agent in several outbreaks of food poisoning. Other investigators have had varying degrees of success in isolating salmonellae from fishmeal. Walker (13) found no positives among 10 samples cultured while Cook, Hobbs, and McCoy recovered salmonellae from 14 of 54 samples studied. Their unpublished report is cited by Walker (13). Rohde and Bischoff (9) found salmonellae in 43 of 270 samples, while Adam (10) reported 16 percent of 833 fishmeal specimens positive for the organism.

In the United States fishmeal is used extensively in a variety of poultry feeds. Of 16 specimens of domestic fishmeal examined bacteriologically by one of the authors (Boring), salmonellae were found in 9 instances. *S. reading* was not among the types isolated, but these specimens were collected during July and August of 1957, well after the peak of the "outbreak." If poultry flocks may in fact become infected with *Salmonella* from contaminated feeds, a potentially major public health problem exists. Thal and co-workers (14) and Seeliger (12) have discussed the probability of infection of domestic animals with *Salmonella* from such contaminated feeds. The danger of human infections from contaminated flocks has been discussed by Abelseth and Robertson (15), Edwards (16), and others.

Clinical and Laboratory Material

Among the 300 or 400 reported acute cases of salmonellosis due to *S. reading*, two deaths occurred in children. A 10-year-old Negro boy died 5 days after onset of symptoms, following a rapidly downhill course. Stool and blood cultures were positive for *S. reading*. The final diagnosis included congenital heart disease, acute and subacute bacterial endocarditis with *Salmonella* sepsis, and sickle cell anemia. His hemoglobin level was reported as 6.2 gm./100 ml. An infant death was reported with no other information available. The only localized *Salmonella* infection reported occurred in a 2-year-old white boy who developed septic arthritis of the calcaneotibial joint. No attempt is made to calculate a case fatality rate in this epidemic for want of a reasonably accurate denominator.

Salmonellosis due to *S. reading* appears to present clinical features similar to those de-

scribed for previous series of patients with *Salmonella* infections (17, 18). However, complications were not present in the study group, although they were reported among patients for whom only incomplete histories were available. The rarity of complications reflects the relatively low virulence and non-invasiveness of *S. reading*. Furthermore, previous reviews referred to dealt only with hospitalized patients, while in the present series half of the patients were not hospitalized. As noted previously, a majority of these patients came from families with above average incomes so that nutrition, sanitation, and medical care approached the optimal level. Eisenberg and associates (18), reporting on a series of 95 patients with salmonellosis seen at the Philadelphia General Hospital noted localized infections in 13 percent of their patients. Many patients in that series were from a lower socioeconomic group, which further sets them apart from the present series of patients. Among 100 infants and children with salmonellosis reported by Clyde (19) from Nashville, Tenn., localization occurred in 9 percent. By comparison with these reports, the 69 patients with *S. reading* infection reported had a relatively mild illness. Nevertheless, 53 percent of the patients voiced the subjective impression that their illness was severe.

Several factors serve to indicate that the "epidemic" of *S. reading* infections was a family affair with a common source of infection in the family. Of the 252 family members exposed in the homes of index cases, 30 percent were either positive for *S. reading* by stool culture or had suffered from gastroenteritis. Even more striking was the finding that in 42 percent of families, at least one secondary illness had occurred. Also, in 55 percent of the 33 families cultured (table 7), at least one contact was found to be positive for *S. reading*. In 55 percent of the 65 exposed families, at least one person was bacteriologically positive or had developed gastroenteritis.

As shown in table 7, mothers were more frequently positive for *S. reading* than were fathers. The significance of this finding is not entirely clear. The mother might be infected or reinfected from her children, who are physically closer to her than they might be to

the father. However, the mother would also be the first member of a family to come in contact with an infected foodstuff. If she prepared this item for cooking, perhaps as with poultry, she might infect herself and other family members by handling salad, the bread plate, the baby's formula, or a host of other items. Necessarily, this is only conjecture.

Two infants aged 2 weeks and one infant 1 week old developed diarrhea, which was later proved to be due to *S. reading*. The mother of one infant had been ill with gastroenteritis prior to delivery, while the mothers of the two other infants were positive for *S. reading* some time later. As has been demonstrated previously (20, 21), these mothers may have infected their newborn infants during parturition. Since asymptomatic carriers of *S. reading* appeared to be common among family contacts (table 6), inadvertent infection of the more susceptible infants and young children may have occurred frequently.

Among the younger patients in this series, a problem was apparent because of the unusually long duration of the convalescent carrier state. Where a series of cultures negative for *Salmonella* was required before hospital discharge, hospitalization was often unduly prolonged. The difficulty and expense of keeping an asymptomatic child hospitalized usually resulted in discharge due to desperation before the required number of negative cultures were obtained. Realistically, greater emphasis should be placed on the child's clinical course in determining the need for hospitalization than on the duration of stool cultures positive for *Salmonella*. Rubinstein and associates (22) have noted the long duration of carrier states with various *Salmonella* types. In a followup study of an outbreak of *S. oranienburg* in a nursery for the newborn Rindge has also noted the long duration of the carrier state in infants (personal communication). Among infants in families without other *S. oranienburg* positive members, the mean duration of the carrier state was about 7 months. Szanton (23) reporting the 40-month followups on this same series of 33 infected infants found, for the total group, that the carrier state persisted for an average of about 14 months. The futility of applying standard "three negative stool" requirements to

young children hospitalized with salmonellosis is emphasized by these findings. Perhaps parents of these children might be instructed in the necessary home precautions so that, when the clinical condition permits, a child could be discharged from the hospital. Subsequent stool specimens could then be obtained at home.

Summary

More than 300 acute sporadic cases of salmonellosis due to *Salmonella reading*, a previously extremely rare serotype, were reported during a 12-month period. Intensive study of food histories from patients in various parts of the country failed to reveal the presumed common source responsible for this "outbreak." A possible but unknown relationship between infected animal feeds and poultry to the present *S. reading* problem is discussed.

Detailed clinical and laboratory data are presented for 69 salmonellosis patients. The absence of complications in this group is noted and discussed. Among 252 exposed family members, 30 percent had either been ill or were found positive for *S. reading* by stool culture. In 55 percent of 65 families studied at least one member had gastroenteritis or was positive for *S. reading*.

Bertha Adkins Named Under Secretary

Bertha Sheppard Adkins was named Under Secretary of Health, Education, and Welfare on July 21, 1958, succeeding John Alanson Perkins who resigned. She had been assistant chairman and head of the women's division of the Republican National Committee since 1953.

From 1934 to 1942 Miss Adkins held the post of dean of women at Western Maryland College and during the following 4 years served as dean of residence at Bradford Junior College in Massachusetts. On graduation from Wellesley College in 1928, Miss Adkins taught in private schools until 1932. She holds a master of arts degree from Columbia University conferred in 1943 and is a life member of Pi Lambda Theta, an honorary society for women in education.

Control of

Radioactive Liquid Wastes

in Pennsylvania

KARL M. MASON, M.P.H.

On September 12, 1957, the Sanitary Water Board of the Pennsylvania Department of Health authorized issuance of a permit to the Duquesne Light Company for the treatment and discharge of liquid wastes from the company's steam turbine power plant employing heat exchanged from a nuclear reactor, at Shippingport. Located on the Ohio River some 25 miles from Pittsburgh, this power reactor is the first such installation in this country with disposition of its waste materials regulated by a State health agency.

When, in early 1954, it became certain that the first commercial power reactor was to be constructed in Pennsylvania, the State department of health and its water pollution control agency, the Sanitary Water Board, looked to their responsibilities. Despite the indecision at the time concerning the jurisdictions of the

Atomic Energy Commission and State agencies, the State health department elected to apply its authority under its general health powers to the adoption of radiation protection regulations. In addition, the Sanitary Water Board classified radioactive liquid wastes as industrial wastes, thus requiring a permit for discharge of any such wastes to the waters of the Commonwealth.

With the assistance of the Radiological Health Branch of the Public Health Service, the technical staff of the bureau of environmental health developed the conditions under which these liquid wastes could be discharged. As a result of the cooperation and competence of officials of the Duquesne Light Company and Westinghouse Electric Corporation, early agreement was reached on the radioactivity limits deemed necessary for the protection of the public health. The company, in its application report, had adhered to the maximum permissible concentrations recommended in Handbooks 52 and 61 of the Bureau of Stand-

Mr. Mason is the director of the bureau of environmental health, Pennsylvania Department of Health.

ards and the requirements of the health department's Radiation Protection Regulation. However, as indicated by the permit accompanying this article (p. 898), in the interest of public health protection, more stringent requirements were incorporated into this document than are recommended by national authorities.

The Reactor and Its Wastes

The Shippingport atomic power station is designed to produce electric energy by a conventional turbine-generator unit. The first reactor core has a rating of 231 megawatts heat, producing a 60-megawatt net electrical output. Subsequent cores will have ratings up to 340 megawatts heat and 100 megawatts gross electrical output. Steam for the turbine is supplied by the primary plant, consisting of the nuclear reactor and its associated systems. This plant is comparable to the furnace and boiler of a conventional power station.

The pressurized water reactor consists of a closed system in which water at high pressure is circulated over an array of nuclear fuel elements (the core) to heat exchangers where steam is formed in a separate, isolated system. The active portion of the nuclear core is a cylinder about 6 feet in diameter and 6 feet high containing highly enriched uranium assemblies (called seed) and natural uranium assemblies (called blanket). The seed assemblies contain a total of 75 kilograms of enriched uranium-235, and the blanket contains 14 tons of natural uranium metal in the form of UO_2 .

The radioactive wastes are classified into eight categories: reactor plant effluents, service building wastes, fuel canal water wastes, spent ion-exchange resin and incinerator ash wastes, combustible solid wastes, noncombustible solid wastes, gaseous wastes, and boiler water. The three main sources of radioactivity which contribute to the liquid wastes are:

1. The activation of corrodible metals, corrosion products, and trace elements in the high-purity reactor coolant water.
2. Fission products released from failed fuel elements.
3. Tritium resulting from activation of the lithium hydroxide added to the reactor coolant water to minimize corrosion in the system.

It is estimated by the company in its report that only about 2.5 percent of the total radioactivity will be discharged to the river. Most of the remainder will be retained in the spent ion-exchange resin storage tanks (97.4 percent); a minute percentage will be discharged as gas to the atmosphere (0.01 percent).

In order to insure that the required degree of treatment is provided, the liquid wastes are sampled and the level of radioactivity determined at each stage of the treatment process. During a long period of retention in underground storage tanks the radioactivity is reduced appreciably by decay, and subsequent processing through the ion-exchangers reduces further the radioactivity of these wastes. Thus, the entire treatment is a series of batch processes prior to discharge to the river, and the wastes may be reprocessed if the samples indicate that the required reduction in radioactivity has not been accomplished. The high-level radioactive wastes which are retained in the ion-exchanger are held for disposition by burial elsewhere at locations supervised by the Atomic Energy Commission.

Safety Factors

The accepted standard applied to the discharge of liquid wastes to streams utilized for public water supplies is that the radioactivity for unknown mixed fission products shall not exceed an annual average of 1×10^{-8} microcuries per milliliter above natural background radioactivity at the next point of use downstream. To provide extra protection for the waters traversing Pennsylvania and to retain a portion of the stream flows for the discharges from future nuclear facilities, several safety factors were added to this standard.

As an example, the sampling point for Shippingport wastes is in the plant's effluent channel containing the condenser cooling water. This location results in an extra safety factor of more than 100 since the maximum amount of condenser cooling water is less than 1/100 of the mean flow of the Ohio River. Another appreciable factor of safety is that the limits of radioactivity apply at any time, rather than to the average concentration over an interval

of 1 year. These same conservative requirements have been incorporated in the permits issued to six other nuclear facilities of various types and will be applied to several applications now under consideration.

In considering the application of the Duquesne Light Company, one of the initial counterproposals of the Pennsylvania Department of Health was that the company reduce substantially its request for an emergency discharge of 700 curies of tritium in 1 day should an accident occur in any of the coolant loops. Although this amount of tritium was below the maximum permitted by accepted standards for an average concentration over an entire year, the company agreed to withdraw this proposal and limit the maximum discharge of tritium during any 1 day to less than 1 percent of the maximum allowable concentration. This agreement is consistent with the objective of the department of health and its Sanitary Water Board to produce and discharge the least amount of radioactivity practicable. Recent analyses of waste discharges from the Shippingport plant indicate that it will be possible to conform to the stringent standards for fission products as well as for tritium.

During 1956 and 1957 the Westinghouse Electric Corporation conducted, under the sponsorship of the Atomic Energy Commission, a site-monitoring program in the vicinity of the Shippingport plant. The purposes of the pre-operational phase of this program were to determine the types and amounts of radioactive materials which occur in the environment around the reactor plant and to determine the variations in the amounts of these materials over a period of approximately $1\frac{1}{2}$ years prior to operation. Analyses were made on (a) soil in the general vicinity of the plant, (b) Ohio River water above and below the site, (c) well water within a 1-mile radius, (d) vegetation in this general area, and (e) the air in the general area.

Although the department of health accepted the reports of Westinghouse's study and assisted in some of the sampling, it decided to initiate further studies in the area in order to encompass all phases of the environment sub-

ject to possible contamination by radioactivity. Through the efforts of the department's public health veterinarian, specimens of animal life and milk products have been collected and analyzed for radiation levels, both in the general area of the plant and in a control area. Using Federal program grant funds, the department has contracted with the University of Pittsburgh to determine the radioactivity levels of all types of aquatic life in the Ohio River above and below the plant site. Since both the department of health and the Duquesne Light Company are continuing the site-monitoring programs on a postoperational basis, data will be available on all of the environmental aspects which could be affected by nuclear facilities in this area.

Summary

Public health authorities in Pennsylvania are administering a program of radioactive liquid waste control in the following manner:

1. Radioactive liquid wastes have been classified as industrial wastes and thus are subject to a permit from the Sanitary Water Board.
2. Since the treatment processes employed at such installations have not been subject to full-scale operation experience, the permits are granted on an experimental basis.
3. For the purpose of insuring protection of the public health and the retention of stream volumes for future discharges, the levels of radioactivity in liquid wastes must conform to more stringent standards than those generally accepted.
4. The conditions of the permit, including the maximum allowable concentrations, are subject to revision if altered conditions or the advance of science and technology so indicate.
5. The discharge of radioactivity shall be kept at the most practicable minimum, regardless of maximum amounts permissible.
6. Adequate analyses and operational reports must be submitted to the department of health.
7. Environmental monitoring programs shall be continued and, if necessary, expanded.
8. Immediate notification of the department is required in the event of accident or discharge in excess of tolerance.

COMMONWEALTH OF PENNSYLVANIA

DEPARTMENT OF HEALTH

SANITARY WATER BOARD

HARRISBURG

INDUSTRIAL WASTES PERMIT NO. 1832

The Sanitary Water Board, which by virtue of the Act of April 9, 1929, P. L. 177, known as The Administrative Code of 1929, and the amendments thereto, and of the Act of June 22, 1937, P. L. 1987, as amended by the Act of May 8, 1945, P. L. 435, is empowered to exercise certain powers and perform certain duties "To preserve and improve the purity of the waters of the Commonwealth for the protection of public health, animal and aquatic life, and for industrial consumption, and recreation; . . .", hereby issues this permit to the Duquesne Light Company, 435 Sixth Avenue, Pittsburgh 19, Pennsylvania, its successors or assigns, approving, subject to certain conditions, the proposed works for the treatment of wastes from the permittee's atomic (nuclear reactor-steam turbine) power plant located in Shippingport, Beaver County, Pennsylvania, with discharge of the treated effluent therefrom into a channel of the Ohio River between its left, or southern, bank and Phillis Island, about 11 miles below the confluence of the Beaver River, in response to an application, undated but attested June 19, 1957.

This plant is designed for the production of 60 megawatts, i. e., 60,000 kilowatts of electrical energy during initial operation. Later, possibly after about a year, and when the present core has been replaced by a more powerful one, the plant is expected to reach a maximum rating up

to 340 megawatts of heat and 100 megawatts gross electrical output.

This application requests approval of "the discharge to the Ohio River of an average of 12,000 gallons per day of waste water containing approximately 10 curies of tritium and 1,590 microcuries of other radioactive materials. This effluent consists, for the most part, of laundry and shower room wastes and neutralized laboratory wastes which are released to the condenser effluent stream at a controlled rate. The lesser portion of the discharge consists of reactor plant wastes. The system consists of gravity collection tanks; intermediate storage and decay tanks; processing by evaporator, ion-exchangers, gas stripper; followed by controlled discharge to the river. Radioactivity is measured at each stage of the process and before discharge." It is to be noted that the term "neutralization," as used above, refers only to chemical neutralization.

The proposed plant and waste treatment works will provide for hatch treatment of all wastes. If in the opinion of the Sanitary Water Board, any wastes are inadequately treated, facilities will be available for recycling such wastes through all or parts of the treatment process until the effluent is satisfactory for discharge to the waters of the Commonwealth when diluted with the normal volume of cooling water. The proposed works are described in

some detail in an engineering report entitled "Duquesne Light Company—Shippingport Atomic Power Station—Shippingport Borough—Beaver County, Penna.—April 20, 1957" and are shown on twelve sketches and diagrams bound with the report and entitled and described as follows:

Artist's Conception of the Shippingport Atomic Power Station.

Also bound with the company's report are two tables, "Table I—Expected Maximum Steady-State

Activity For Non-Volatile Fission Products in the PWR Wastes—Duquesne Light Company—Shippingport Atomic Power Station” and “Table II—Activity Discharged to River—Waste Disposal System—Duquesne Light Company—Shippingport Atomic Power Station.”

The report and plans were prepared by J. A. Tash, Eng., Power Stations Dept. of the Duquesne Light Company. The report is signed by W. J. Lyman, a professional engineer, Pennsylvania Registry No. 5582, Vice-President, Operations Division, Duquesne Light Company, and stamped as received in the Pennsylvania Department of Health, Division of Sanitary Engineering, Region III, on June 21, 1957.

These plans are hereby approved subject, nevertheless, to the condition that the waste treatment plant to be constructed under said plans will produce an effluent satisfactory to the Sanitary Water Board. By this approval, neither the Board nor the Commonwealth of Pennsylvania assumes any responsibility for the feasibility of the plans or the efficiency of the operation of the plant to be constructed thereunder.

This permit is issued subject to the following Special Conditions:

A. The waste treatment facilities shall be constructed and ready for operation coincident with the start of power operation of the reactor.

B. Approval of plans refers to waste treatment and not structural stability, which is assumed to be sound and in accordance with good structural design. Failure, because of faulty structural design or poor construction, of the works herein approved will render this permit void.

C. Since the herein approved works employ principles not at present considered conventional, they must be regarded as *experimental* and the subsequent action of the Sanitary Water Board will depend on actual performance in eliminating the objectionable characteristics of the waste waters as discharged from the works in question.

D. The discharge of untreated or improperly treated industrial wastes to the waters of the Commonwealth

is contrary to the requirements of the Sanitary Water Board. If, because of accidental breakdown of the treatment works or plant equipment or for any other reason, any such discharge should occur, then the operation of any process producing such discharge shall be discontinued until repairs to the treatment works or other satisfactory measures to prevent stream pollution shall have been completed.

E. The permittee is hereby directed to immediately notify the Pennsylvania Department of Health whenever there is a spill or an accidental discharge of radioactive material and shall advise that Department promptly concerning the pertinent facts and probable danger. The permittee shall maintain rosters of Pennsylvania Department of Health personnel and of downstream users of river water who shall be notified. The necessary information for such rosters shall be furnished to the permittee by the Department of Health. In the event of any such accidental discharge, the Department of Health shall determine whether or not downstream users shall be notified, and by whom.

Moreover, the permittee is required to see to the training and supervision of all operating personnel, in order to prevent the discharge of such material, fluid or solid, to the waters of the Commonwealth or to the site, without adequate treatment.

F. All industrial wastes discharged to the portion of the Ohio River on which the permittee's plant is located shall meet at least the requirements of the Sanitary Water Board for primary treatment. “Primary treatment” does not apply to the radioactive characteristics of the wastes.

The term “primary treatment,” as here used, is such treatment of sewage as, in the opinion of the Board, will remove practically all of the settleable solids; will remove at least 35 percent of the organic pollution load as measured by the biochemical oxygen demand test; will accomplish the removal of oils, greases, acids, alkalis, toxic, putrescible, taste- and odor-producing

substances, and other substances inimical to the public interest in the receiving stream; will provide effective disinfection to control disease-producing germs; will provide for satisfactory disposal of sludge; and will produce a final effluent that is suitable for discharge into the receiving stream. “Primary treatment of industrial wastes,” as here used, is treatment to a degree equivalent to that set forth herein for sewage.

Moreover, because of the radioisotopes which these wastes may carry, such wastes shall be substantially free of turbidity and suspended solids over and above the amounts of such characteristics in the intake water.

G. The treated radioactive liquid wastes as discharged to the Ohio River shall comply with the Pennsylvania Department of Health Radiation Protection Regulation 433 and any subsequent regulations of the Department of Health.

H. With respect to the amount of radioactivity released in the liquid wastes to the waters of the Commonwealth, this permit is issued subject to the following conditions: (1) that the average radioactivity, exclusive of tritium activity, of these wastes over any consecutive 365-day period shall not exceed 1,590 microcuries per day, with the maximum discharge not exceeding 6,200 microcuries per day, (2) these wastes shall at no time carry more radioactivity, exclusive of tritium activity, than 10^{-6} microcuries per milliliter in excess of that of the plant intake water from the Ohio River, and (3) that the discharge of tritium in these wastes shall be not more than 10 curies per day averaged over any consecutive 365-day period, nor more than 50 curies per day maximum. Moreover, the company shall conduct all its pressurized water reactor operations so as to produce and discharge the least practicable amounts of radioactivity.

I. Although tritium has a short biological half-life (19 days) and a maximum permissible concentration (MPC) of 0.2 microcuries per ml. (according to Handbook 52 of the National Bureau of Standards) as compared with an MPC of 10^{-6} micro-

curies per milliliter for the general population for unidentified isotopes, its radiological half-life is long enough (4,600 days) to make its continued presence in the stream undesirable and possibly inimical to aquatic and other life. At the present time, it is reported, there are no practical means for its separation from a liquid. The permittee, however, shall continue to investigate and apply more effective means to remove this potential hazard as rapidly as such means are developed, or attempt to devise some other means or to attempt to find some other substance which will have advantages similar to that of lithium hydroxide without producing the present discharge of tritium. The attention of the permittee is directed to the possibility that tritium may prove objectionable as a constituent of water used for certain industrial processes.

J. The radioactive and other liquid wastes discharged to the effluent channel shall be well admixed with the cooling water so that the waste content of this channel shall be substantially uniform below the effluent weir or at the sampling rake.

K. The treated effluent shall be discharged to the river in a manner acceptable to the Sanitary Water Board. If any structure is necessary to accomplish this, it shall be well protected against the effects of flood waters, ice, and other hazards and the design of such structure shall be acceptable to the Sanitary Water Board.

L. Provision shall be made for regulating the discharge of the treated effluent so that it shall be equally distributed over the longest practicable period, in order that advantage may be taken of maximum possible dilution by the receiving stream, and means to accomplish uniform 24-hour distribution shall be provided if in the opinion of the Department of Health this shall be found necessary.

M. The wastes after treatment and prior to discharge to the effluent channel shall contain no more than 0.05 p.p.m. of hexavalent chromium and 1.0 p.p.m. of trivalent chromium.

N. The permittee shall provide means for measuring the total volume as well as variations in the rate of discharge of all waste water. Equipment to automatically record this information shall be provided promptly if directed by the Department of Health.

O. Any solid waste material including radioactive material shall be so handled that a nuisance is not created, and shall be disposed of in a safe and sanitary manner to the satisfaction of the Department of Health and in accordance with the provisions of the Pennsylvania Department of Health Radiation Protection Regulation 433 and any subsequent regulations of the Pennsylvania Department of Health.

P. It is required that a sampling schedule be maintained and that records thereof be kept together with records of the operation of the waste disposal system, and that such data be submitted in reports to the Department of Health, covering such particular matters and at such intervals as the Department may direct, beginning within two months after the initial operation of the plant. It is noted that the report submitted with the present application indicates that records will include:

1. Accumulation rate and activity for each class of waste by days.
2. Changes in activity of wastes during processing.
3. Volume and activity of waste discharged.
4. Time of day and duration of discharge with volume and activity automatically recorded.

The special nature of the wastes produced at the permittee's Shippingport plant may cause the Sanitary Water Board to require additional sampling, analysis, and testing of the surface and underground waters in the vicinity, particularly of the Ohio River at points above and below the plant, in order to determine the effects of radioactivity on these waters.

The report submitted to the Board by the permittee, in support of its permit application, indicates that such sampling is being conducted at present by or under the sponsorship

of the U. S. Atomic Energy Commission. If for any reason, however, the AEC does not continue this sampling, or if in the opinion of the Sanitary Water Board additional data are needed, the permittee may be required to conduct such sampling and analysis as the Board may direct.

Q. Acknowledgment is made of the company's study now in progress to determine temperatures and percentage of river volume that flows through a narrow river channel between Phillis Island and the mainland to determine the expected rise in river water temperature in this channel when the condenser cooling water is discharged to it. The permittee is hereby advised that the river water temperature rise is tentatively limited to 2° F. at points to be determined by the Sanitary Water Board after the results of the thermal studies of the channel and of other data have been reviewed, and that if this limit cannot be maintained with the proposed method of discharge, then complete dispersal of the condenser effluent in the river, or other means for temperature control, may be necessary. The report on the river channel study shall be submitted in duplicate to the Sanitary Water Board within 60 days of completion of the study which is expected to terminate in the last months of 1958, with progress reports on a quarterly basis.

R. The permittee shall submit to the Sanitary Water Board a comprehensive report on the operation of the herein approved treatment works within six weeks after completion of the first half-year of operation, and within a similar period of time subsequent to any substantial change in the operating capacity of the plant or any other marked change in operation or waste treatment. The report shall include pertinent information as to waste volumes, radioactivity before and after waste treatment, the general adequacy of these works in treating all waste discharges from this establishment so as to meet the requirements of the Sanitary Water Board for primary treatment, an overall estimate of the success achieved in (1) the

reduction of the pollution carried to the stream and (2) in the continuous maintenance of a final liquid effluent meeting the requirements of the Board as to uniform admixture with the cooling water.

S. If the effluent as produced by the waste treatment works herein approved shall in the opinion of the Sanitary Water Board prove to be of quality unsatisfactory for discharge into the receiving stream, by reason of the creation of a public nuisance, or because of change in the character or volume of the wastes, or in the use or condition of the receiving stream, or for other reason; or because in the Board's opinion such discharge is or may become inimical or injurious to the public health or to animal or aquatic life or to the use of the receiving body of water for domestic or industrial consumption or for recreation, then a higher degree of treatment (by means of additional plant units or otherwise) shall

be provided. Plans for additional works shall be prepared promptly after notice from the Board so to do, and after approval of the plans by the Board, the additional treatment shall be provided and placed in operation within such time as the Board shall require. No construction shall be undertaken without such approval.

T. This permit will be subject to review from time to time by the Sanitary Water Board, and to change if so indicated by altered conditions or the advance of science and technology.

And this permit is further subject to the following numbered Standard Conditions of "Standard Conditions Relating to Industrial Wastes" effective January 1, 1941, attached hereto: 1, 2, 3, 6, 7, 13, 16, and 17.

[NOTE: These standard conditions require adherence to prior permits or orders, compliance with the approved construction plans and with

the established effluent standards, adequate supervision during construction, notification of the department of health when construction is completed, proper maintenance of treatment facilities, and permission from Federal authorities for the installation of stream structures.—
EDITOR]

This permit is issued in response to an application (No. 12234-IW) filed in the Harrisburg office of the Pennsylvania Department of Health on the 22d day of June A. D. 1957, and in accordance with the authorization given by the Sanitary Water Board at its meeting on September 12, 1957.

Tuberculosis Casefinding in Schools

The Public Health Service, the Office of Education, and the Children's Bureau have suggested that school and college officials and health departments assess existing tuberculosis casefinding programs among students and employees in the light of the recent official statement of the Public Health Service on X-ray Casefinding Programs in Tuberculosis Control, published in *Public Health Reports*, January 1958.

The Committee on Health of the School Age Child, a joint body of the three agencies of the Department of Health, Education, and Welfare, has made these recommendations:

1. Tuberculosis casefinding programs for children, youth, teachers, and other school personnel should be evaluated and planned in the light of current knowledge concerning the prevalence of tuberculosis and the effects of radiation on the human organism. Profes-

sional assistance and advice should be sought from the appropriate State or local health department.

2. Laws and regulations that make periodic chest X-ray examinations compulsory for students, teachers, and other school personnel should be reviewed and modified if necessary to allow health authorities to select the most effective current methods and to utilize applicable new knowledge and techniques of tuberculosis control.

3. Consideration should be given to the use of the tuberculin test as the initial screening device to be followed by a chest X-ray of reactors. The percentage of reactors in some school and teacher populations is low enough to make this a practical procedure.

4. X-ray equipment should be periodically checked and adequate safeguards applied to protect all persons from unnecessary radiation.

Nursing Care for Hemiplegic Patients

Nursing care of hemiplegic patients, the victims of stroke, occupied the 1958 seminar in cardiovascular nursing conducted by the Heart Association of Southeastern Pennsylvania in Philadelphia last February.

The proceedings published by the association consist of papers describing the nature, needs, and management of the condition.

More than a million Americans suffer hemiplegia, said Dr. William J. Erdman II of the University of Pennsylvania School of Medicine. Attacks, resulting from a block of the brain's blood supply, occur at any age. Effects may include a loss of consciousness; flaccid paralysis, usually up to a few days; spasticity in the flaccid area; inability to communicate, although hearing and understanding may be unimpaired; inability to judge what is vertical; loss of the sense of touch; and a painful shoulder.

Dr. Erdman recommended an optimistic attitude, which can be communicated to the patient by explaining the prospect for recovery; accepting the patient's limitations without criticism; drawing favorable attention to each sign of recovery; encouraging patients to do as much for themselves as they are able, without posing tasks so formidable as to discourage them; and encouraging hobbies or employment for the homebound. Although progress is slow, he said, 4 out of 5 patients regain ability to take care of personal needs.

Vera Ford Powell of the Albert Einstein Medical Center's home care program offered specific advice to nurses. The attitudes of the family and the patient must be understood if therapy is to be effective, she said. "The patient is frightened, anxious, and angry. There is never consistency in the cooperation of a patient. The family develops attitudes of pity, hostility, and rejection. Too much help is not good for the patient."

For the nursing of an aphasic (speechless) patient, she advised a relaxed attitude; a calm, friendly, and secure atmosphere; acceptance of the patient's inability to talk; and acceptance

of the tendency of the patient to resort occasionally to infantile language or to vile outbursts. She warned nurses not to anticipate what the patient is trying to say, not to say it before the patient has expressed it in full. Recovery, she emphasized, proceeds from tactfully but persistently encouraging the patient to say basic words and perform essential movements in all activities of the day.

Occupational therapists, physical therapists, and others participated in the meeting, which included discussions of self-help devices for the partially paralyzed.

✓ Strike Back at Stroke

A major obstacle in management of stroke patients has been a problem of communication between physician and the patient's family. The above illustration is typical of those used, with appropriate legends, in a new Public Health Service publication, *Strike Back at Stroke*, to explain how to move and exercise stroke victims. The book contains 21 therapeutic exercises and is arranged so that the physician can prescribe for the patient's specific needs.

Demands for this publication have been such that the first edition was sold out before it was announced in *Public Health Reports* in August. Health departments are distributing copies to physicians.

To prepare the illustrations in this book, approximately 250 photographs were taken of the more typical procedures used in treating hemiplegic patients. Drawings were made from the photographs selected by a group of consultants who assisted in the development of the book.

Developing an Ordinance and Code for Food Vending Machines

WILLIAM C. MILLER, Jr., M.S.

THE AUTOMATIC merchandising of food has grown from the penny candy vendor to prototype machines which dispense an entire hot meal at the touch of a button. A billion dollars for foods and beverages was dropped into coin slots in 1957, and vending machines are now supplementing snack bars and cafeterias in many factories and offices.

With the rapid expansion of this type of food buying, many States and communities and the trade organization of the industry requested the Public Health Service to develop a model sanitation ordinance and code for vending machines. Culminating 4 years of study and investigation, the recommended ordinance on the vending of foods and beverages was published in July 1957 (1). This suggested legislation is not solely a product of the Public Health Service. It also represents the views of State and local health officials and the vending machine industry.

The development of model ordinances and codes for nationwide use is not an easy task. Such a document aims to meet every situation in every State and community. The definitive provisions must reconcile the strict public health point of view, which may not recognize some of the operating problems, and the strict industry

point of view, which may not recognize some of the public health considerations. Accordingly, a model or suggested ordinance represents a series of compromises which afford maximum public health protection and yet can be attained in practice.

History and Growth

The history of automatic merchandising starts about 200 B. C.; the first vending machine of record dispensed holy water in a Greek temple in Alexandria, Egypt. In the early part of the 19th century, bulk tobacco was automatically merchandised in English pubs. Vending machines first appeared in the United States in the late 1880's. Penny gum and chocolate bars were dispensed in packages and salted peanuts and ball gum in bulk. Although cigars appeared in vending machines around the turn of this century, not until the mid-1920's were cigarettes so merchandised. Prior to World War II most vending machine operations were in the penny sales category (2).

During the past few decades, the vending industry has undergone phenomenal growth and technical change. Few facts and figures are available that accurately indicate the magnitude of the industry prior to 1950. However, personal observation and limited information indicate that food and beverage vending machine operations in the 1930's and early 1940's were primarily small businesses, with individuals owning and operating only a few machines.

Demands for infant feeding during World War II increased the number of vending ma-

Mr. Miller is chief of the Food Sanitation Section, Milk and Food Program, Division of Sanitary Engineering Services, Bureau of State Services, Public Health Service. This article is based upon a paper presented at the annual meeting of the South Carolina Association of Sanitarians, Inc., at Myrtle Beach, S. C., May 23, 1958.

chines which assisted in meeting the needs for on-the-job refreshment. Subsequently, the automatic merchandising of foods and beverages in factories, office buildings, institutions, and other locations began to supplement and, in some instances, to replace the small cafeteria or snack bar.

The estimated total sales of products through vending machines in 1947 approximated a half billion dollars. In 1957, total sales exceeded \$2 billion, about half of which were foods and beverages. The automatic vending of foods and beverages accounts for a large part of the increases during the past few years. For example, about 2,000 coffee vending machines were in use in 1949, with sales of about \$1.5 million. In 1957, the sales of 70,000 machines dispensing coffee and other hot beverages were more than \$135 million, an increase of 35-fold in machines and 90-fold in dollar sales. Similarly, sales of milk and milk products increased more than four times between 1953 and 1957. Sandwich and pastry sales have tripled since 1953 (2).

Until the last few years, most foods and beverages dispensed through vending machines were not readily perishable. However, as the industry expanded, the variety of products dispensed began to include many readily perishable products, such as hot and cold sandwiches, meat dishes, soups, and salads. Currently there are prototype machines which hold precooked frozen meals and dispense these meals hot in a matter of seconds. The expansion has introduced new products in food merchandising and public health protection normally not encountered in conventional food service businesses.

Requests for a Code

The earliest activities of the Public Health Service in connection with the vending of foods and beverages date back to the late 1940's. The changing character of automatic merchandising prompted a number of States and communities to request the Service to furnish opinions on the public health hazards of certain types of vending machines. Opinions delivered were based on the sanitation standards in the existing restaurant and milk ordinances and codes.

As the vending of perishable foods expanded, many States and communities requested the

Service, in the interest of uniformity, to develop specific criteria which could be recommended for the sanitary control of foods merchandised in this manner. The National Automatic Merchandising Association, a trade organization representing the equipment manufacturers, the operators, and the suppliers, also requested the Service to formulate a model vending machine sanitation ordinance and code.

This work began in 1954. The Milk and Food Program of the Division of Sanitary Engineering Services made field studies of current practices in vending machine design, construction, and operation. The problems encountered were discussed in detail with individual State and local health authorities, representatives of the vending industry, and others concerned. Conferences were held with groups and individuals who had or were engaged in research related to vending machines.

Next, existing ordinances and regulations specifically concerned with the sanitary control of vending machines were reviewed. In 1954, only six local health departments reported that they had adopted such regulations; however, many indicated they felt there was a need for sanitary control of food and beverage vending. The most comprehensive standards reviewed at that time were those developed for the Armed Forces by the Subcommittee on Food Supply, Committee on Sanitary Engineering and Environment, National Research Council. The industry representatives indicated that the general criteria established in these standards were practical for all types of vending operations, although the standards were limited to coin-operated, bulk-type vending machines which dispensed beverages or liquid foods.

The first working draft of the ordinance was completed in 1955 and was discussed with members of the industry. In April 1956, the second working draft was submitted for review and comment to all States, a representative number of communities, several Federal agencies, the vending machine industry, and interested groups and persons. More than 800 groups and individuals had the opportunity to review and comment on the second draft, and their comments proved invaluable in preparing *The Vending of Foods and Beverages* for publication.

Basic Assumptions

The ordinance and code is based upon several major assumptions. The first is that it will be adopted only by jurisdictions having established food sanitation programs. Accordingly, the criteria of existing programs are the basis for the acceptability of foods, beverages, and ingredients; acceptability of the commissaries providing the foods, beverages, ingredients, supplies, and equipment; and acceptability of cleaning methods and bactericidal treatment of the surfaces of the machine in contact with the product. Second, ordinance provisions should be directed primarily toward the protection of readily perishable foods, but should cover public health considerations of vending machines dispensing all types of products.

And third, vending machines are unique; generally they are unattended food dispensing devices and must be self-contained units with the necessary built-in controls for protection of foods or beverages. In reference to this, it is recognized that the health authority, as well as industry, may find it desirable to cover automats, or attended vending machines, under the existing regulations for food service establishments. If this procedure is followed, such businesses should conform fully to the requirements for food service establishments.

The format of the ordinance has been designed to permit flexibility in methods of enactment or adoption. It includes a short enabling form for use by those jurisdictions where adoption by reference is legal. Use of this form reduces cost of publication and printing and facilitates keeping the ordinance up to date. To be adopted only as an ordinance, the code material concerning satisfactory compliance under section V should be deleted. The unabridged version has been arranged and presented in a form that can be adopted as an ordinance and code. When the unabridged form is adopted, section IX, enforcement interpretation, should be deleted.

Briefly, these are the major provisions of the ordinance.

Section I defines the terms used in interpretation and enforcement. This is an essential section of any regulation because specificity of intent must be delineated both for those administering the ordinance and for those regulated

by it. Such terms as "vending machine," "commissary," "machine location," "readily perishable food," "operator," "employee," and "health authority" are defined.

A surprising difficulty was encountered in trying to define "readily perishable foods." Most of those concerned with food sanitation have a pretty firm idea of what is meant by "readily perishable foods." But try to write a definition that is clear, concise, and definitive! To find one, the counsel of representatives of the Food and Drug Administration, the offices of the Surgeons General of the Army, Navy, and Air Force, the National Institutes of Health, universities, and State and local health departments was sought. The definition in section I reflects the combined thinking of a group of people primarily concerned with food protection.

Permits

Permit requirements are normally a part of most food sanitation laws or regulations and from a public health point of view are a registration device to give the health authority a measure of the magnitude of operations requiring program coverage. Section II of the ordinance establishes for permits requirements governing application, issuance, suspension, revocation, and reinstatement.

It soon became obvious in developing permit requirements that they could become an administrative monstrosity to the health authority and the operator. A large number of operators or a single operation of any size would make it almost impossible for the health authority to maintain a current list of all machine locations. Therefore, the operator is required to maintain such information and to make it available to the health authority of the jurisdiction upon request. Permits are not required for each machine but are issued to each operator. The operator's permit number, of a size and style approved by the health authority, should be conspicuously displayed on each vending machine so that in a public health emergency involving a given machine, the health authority can readily identify and contact the responsible operator.

In applying for an operator's permit, the applicant must advise the health authority of the

products to be dispensed, and whether the products will be dispensed in bulk or packages. To keep his permit, the operator must also notify the health authority of any change in types of vending machines or conversion of existing machines to dispense products other than those for which the permit was first issued. Permits, of course, are nontransferable.

Section III prohibits the sale of misbranded or adulterated foods or beverages, and provides for the examination and condemnation of such products.

The inspection of vending machines and commissaries is covered in section IV. Vending machines dispensing readily perishable foods or beverages and all commissaries should be inspected at least once every 6 months. Machines dispensing other than readily perishable products, for example, peanuts, popcorn, and carbonated beverages, should be inspected as frequently as the health authority deems necessary and practical. In addition to authorizing and requiring inspections, this section requires the operator to provide the health authority with access, either in the company of an employee or otherwise, to the interior of all vending machines he operates.

The health authority is required to notify the operator of unsatisfactory findings of an inspection and to establish a specific, reasonable period of time for correction. When conditions are grossly insanitary, or a substantial hazard to the public health exists, the health authority can, with due process, require the immediate discontinuance of operation.

Sanitation Requirements

The sanitation requirements for vending machines and their operation are set forth in section V. Obviously these requirements must be based on the type of food or beverage dispensed. For example, the vending of prepackaged chewing gum hardly presents a danger to the public health, but the vending of milk, sandwiches, salads, and a variety of other readily perishable foods can be potentially hazardous. This section is concerned primarily with the vending of perishable foods and beverages; however it also includes general provisions which are applicable to all vending

machines. An effort was made to cover by specific requirements particular foods or types of vending operations which present a potential health hazard.

Section V is quite detailed and is presented in eight parts. Part A concerns the protection and wholesomeness of foods, beverages, and ingredients, at their sources and in the vending machine, and the protection and maintenance of surfaces of containers and equipment in contact with the product. It requires that readily perishable foods within the vending machine be held at a temperature not higher than 50° F. or not lower than 150° F., whichever is applicable.

Controls are required to insure the maintenance of these temperatures at all times, provided that an exception may be made for the actual time required to fill or otherwise service the machine, and for a recovery period of 30 minutes following the filling or servicing operation. These controls are required to be such that, in the event the temperature in the food storage compartment rises above 50° F. or falls below 150° F., the machine is placed in an inoperative condition until serviced by the operator. The food storage compartment of vending machines dispensing readily perishable foods must have a thermometer with an accuracy of $\pm 2^\circ$ F.

Two points about the temperature controls should be emphasized. First, the 30-minute bypass of the machine cutout is not required but is permitted because of a practical operating problem. The possible public health hazard is calculated to be relatively small. Second, if at the end of this 30-minute period and at any time thereafter, the temperature of the food storage compartment fails to meet required standards, the dispensing mechanism must become inoperative pending the operator's servicing of the machine. Thus, unless the readily perishable products put into the machine at servicing meet temperature requirements, the machine is likely to become inoperative after not more than 30 minutes.

Milk and fluid milk products offered for sale through vending machines must be dispensed only in individual, original containers or from bulk containers filled at the milk plant. This requirement is excepted when the fluid milk

product is an ingredient in liquid foods or beverages dispensed at 150° F., such as in a coffee machine. In this circumstance, the milk product may be transferred at the machine location from the original container of not more than one-half gallon capacity to the vending machine bulk container which is clean and which has been subjected to approved bactericidal treatment. In such a transfer, the entire contents of the original container must be used.

This exception is a necessary compromise, since dairy-filled containers for fluid milk products, suitable for vending machine use, were not available at the time the ordinance was developed. It is understood that several equipment manufacturers are working on this problem with promise of success.

The cleaning, filling, and protection of containers used in bulk milk vending machines are consistent with the provisions for bulk milk dispensers as set forth in the milk and restaurant ordinances recommended by the Public Health Service.

All parts of vending machines in contact with readily perishable products are required to be cleaned and bactericidally treated daily, unless these parts are kept at all times at a temperature not higher than 50° F. or not lower than 150° F. The frequency for cleaning the contact surfaces and parts of other types of vending machines, such as carbonated beverage or popcorn machines, is established by the health authority. The operator should maintain within machines of this type a date record of cleaning and bactericidal treatment. Protection of single service containers used in vending machines dispensing foods or beverages in bulk is also specified.

Other Requirements

Part B requires that the machine's location have a minimum potential for *contaminating* the product and that the location be easily cleanable and kept clean. Part C, exterior construction and maintenance, specifies that machines be sturdily constructed and that exteriors be designed, fabricated, and finished to facilitate cleaning and minimize the entrance of vermin. Screens for ventilation louvers are required; however, because of the large number of ma-

chines currently in use which are not screened, the requirement is deferred for these machines until they are relocated or removed from present locations for any other purpose.

Part D, covering interior construction and maintenance, provides that all interior surfaces and component parts of vending machines be so designed and constructed as to permit easy cleaning and being kept clean. It further requires that all surfaces in contact with the product be smooth, nontoxic, corrosion resistant, and be made of relatively nonabsorbent material. Such surfaces must be protected from contamination and be capable of withstanding routine cleaning and bactericidal treatment.

Inplace cleaning of pipes and tubing of all machines dispensing other than readily perishable foods is permitted. This practice is acceptable if pipes and pipe fittings are so arranged that cleaning and bactericidal solutions can be circulated throughout the system, these solutions *contact* all interior surfaces, the system be self-draining or otherwise completely emptied, and the procedures result in thorough cleaning. The vending stage of all bulk food or beverage machines must have a tight-fitting, self-closing door or cover that remains closed except when food or beverage is delivered.

Part E provides that water used in vending machines be from an approved source and be of a safe, sanitary quality. Water used as an ingredient of the product must be piped into the machine under pressure, with connections and fittings installed in accordance with local and State plumbing regulations.

While the water supply provisions of this ordinance were being developed, information was received concerning several outbreaks of illness attributed to copper poisoning from post-mix carbonated beverage machines. In almost every instance, investigation revealed that there had been a breakdown of the check valve in the water supply line upstream from the carbonator. Specific provisions were therefore developed to protect against such occurrences.

Post-mix carbonated beverage machines are required to have two check valves or a double one; or an air gap; or a device to vent carbon dioxide to the atmosphere; or other device

approved by the health authority which will prevent carbon dioxide or carbonated water from entering the water supply system. All contact surfaces downstream from the protective device are required to be of such material as to preclude the production of toxic substances which might result from interaction with carbon dioxide or carbonated water. If check valves are used, a screen of not less than 100 mesh to the inch must be installed in the supply line immediately upstream from the valves. This screen is to remove any particulate matter which might lodge between the valve and its seat and which might be of sufficient size to nullify the valve's purpose.

Part F, waste disposal, states that all trash and other wastes must be removed from the machine location as frequently as necessary to prevent nuisance and unsightliness and must be disposed of in an approved manner. Machines dispensing liquid products in bulk should have containers to collect drip, spillage, overflow, or other liquid wastes. An automatic shutoff is required which will place the machine out of operation before the liquid waste container overflows.

Part G requires that foods, beverages, and ingredients, and the surfaces of containers, equipment, and supplies in contact with the product be protected from contamination while in transit to machine locations. Further, readily perishable foods while in transit must be maintained at a temperature not higher than 50° F. or not lower than 150° F. This provision does not necessarily require a refrigerated or heated truck, but does require maintenance of these foods at appropriate temperatures. A well-insulated container might suffice, depending on the distance and size of the operation.

That employees have clean hands and wear clean outer garments while handling foods, beverages, and surfaces in contact with products are not only standard requirements in food ordinances but are good business practices as well. This provision is in part H.

Sections VI and VII provide for communicable disease control related to vending machines, and for necessary action when disease is suspected.

Some automatic merchandising businesses are both intrastate and interstate operations.

Section VIII provides for reciprocal inspection of commissaries and permits the health authority to accept reports from the responsible health authorities in other jurisdictions where commissaries may be located.

Enforcement interpretation, penalty provisions, repeal and date of effect, and the unconstitutionality clause, all standard provisions, are set forth in sections IX, X, XI, and XII, respectively.

Industry Efforts

It would be remiss to fail to recognize the industry's part in the promotion of vending machine sanitation. Only a few small outbreaks of illness attributed to foods or beverages from vending machines have been reported to the National Office of Vital Statistics. However, the rapidly changing technology in this type of food service has substantially increased the potential for foodborne outbreaks. This potential was recognized early by a number of forward-looking members of the vending machine industry. Led by the Public Health Committee of the National Automatic Merchandising Association, vending machine manufacturers and operators assisted in the development of the ordinance and code and have endorsed its provisions. In addition, many of the new vending machines are already being designed and fabricated with greater attention to sanitation, and an aggressive public health program has been initiated by and for the industry.

Adoptions

California and Indiana are using the recommended ordinance and code as the basis for State laws or regulations. Many of its provisions are being incorporated into New York City's sanitary code, which is currently under revision. It is also serving as the basis of vending machine sanitation requirements being prepared by the District of Columbia and the city-county of Denver.

Total implementation of the vending machine ordinance and code, whether at State or local levels, ultimately depends upon the development of genuine cooperation, personal as well as official, between sanitarians and vending

machine operators. In the interest of effective vending machine sanitation, it is suggested that health officials get to know the operators in their jurisdictions. By making some rounds with local operators, sanitarians can become acquainted with machine operations and servicing and learn the public health and operational problems associated with various machines. The result will be a sharing of "know how" and an interchange of ideas and experiences. This sort of cooperation pays big dividends in the area in which we all work—the

protection of the health of Americans everywhere.

Nutrition Quiz

A nutrition quiz for dental hygienists of the New York City Department of Health was held April 26, 1957, at the Fort Green Health Center in Brooklyn. The idea for this quiz originated with the borough consultant in dentistry for Brooklyn, who was looking for a stimulating and novel training activity.

Nutrition has always been an integral part of the Brooklyn dental hygienists' inservice training. Customarily, nutrition consultants and supervising dentists from the New York City Department of Health plan group meetings, often held during school vacations, and hold conferences with individual hygienists on specific problems during this inservice training.

Representatives from the hygienists' group, the borough consultants in dentistry and nutrition, the supervising dentist, and three district nutritionists attended a planning session for the quiz. It was decided

that the hygienists would volunteer to study specific nutrients such as vitamins, protein, and minerals as well as calories. Each hygienist was expected to study her topic and to become a "specialist" in answering questions concerning it. The hygienists also agreed to submit questions on their chosen topics.

These questions were then edited and revised by the dentists and nutritionists. The questions were geared to personal nutrition needs as well as those the hygienists met in the field.

For the quiz, all of the 50 hygienists attending were divided into two teams, each with a captain. Each team had its own specialists who had studied their respective nutrients. The consultant in dentistry acted as quiz master, hygienists as team captains and timekeepers, and nutritionists as scorekeepers.

Typical questions were: Define a vitamin. Give five symptoms of a vitamin C deficiency. Name five results of insufficient dietary protein. Is it true or false that fruit is low in calories?

Questions were put first to non-specialists who earned a score of 2

for a correct reply within 30 seconds. A question unanswered within this time limit was turned over to a specialist, whose reply was worth one point. The nutritionists, as they kept score, made notes of challenged answers, points needing explanation, and questions which no one answered correctly. Fifty-five questions were posed during the hour-and-three-quarter morning session.

The nutritionists used the luncheon following the quiz to dramatize the subject of nutrition. Each platter of food on the buffet table bore a sign identifying its nutritional value.

The participants' interest remained high for the afternoon session when the nutritionists took up debated and unanswered questions. Using teaching devices such as bar graphs and posters, they explained points brought up during the quiz, stimulating further discussion.

The day's activities culminated with the announcement of the quiz prize winners. Prizes provided by the nutritionists for each member of the winning team were oranges, grapefruit, carrots, spinach, escarole, chicory, green celery, apples, and cans of dry, nonfat milk solids.

—HILDA KREIGENHOFER, *borough consultant in nutrition, bureau of nutrition, New York City Department of Health.*

Machines that vend carbonated beverages have occasionally been the source of copper poisoning. Poisoning can be prevented if contact between copper lines and carbonated water is precluded.

Copper Poisoning From Vending Machines

SAMUEL H. HOPPER, Ph.D., and HAROLD S. ADAMS, B.S.

SEVERAL health departments have reported cases of illness that appear to be copper poisoning associated with carbonated drinks obtained from vending machines. These machines, the post-mix type, release 1 ounce of a flavored syrup into a cup and then add 5 or more ounces of carbonated water.

In the reported instances of alleged poisoning, the individuals who became ill developed symptoms generally described as acute gastric upset about 12 hours after the vending machine had been in use. The cases of poisoning seemed to occur only after a faulty check valve allowed carbon dioxide to flow into a copper waterline connecting the machine to the building's water supply. Where there is a faulty check valve, the carbon dioxide usually flows back into the water supply because the gas pressure in the tank is greater than the pressure in the building's waterline.

Our investigation at the University of Indiana was conducted to determine whether copper poisoning could result from a carbonated beverage dispensed from a post-mix machine that uses a copper waterline.

Review of Copper Poisoning Cases

Case 1. Twelve persons became ill in a manufacturing plant at Kokomo, Ind., on February 13, 1952. Detailed accounts of sickness were obtained from five persons. There was extensive corrosion of the copper cylinder in a water filter. The carbon in the filter con-

tained 0.43 mg. copper per gram, which is equivalent to 430 ppm.

Case 2. Information from the Office of the Surgeon General, Department of the Army, indicates that defective check valve on a machine at Fort Hamilton, N. Y., in January 1957, resulted in carbonation in the copper waterline. Three persons became ill and laboratory analysis showed 35 ppm copper in the water. Reports of carbonation in a waterline, with no reference to any illness, were also made for First Army Headquarters and a naval receiving station in New York.

Case 3. F. A. Korff of the Baltimore City Health Department reported in a personal communication that a 4-year-old boy was admitted to Union Hospital in Baltimore, Md., on April 3, 1957, with a complaint of vomiting, which started immediately after drinking a carbonated beverage from a vending machine. The child was sufficiently improved to be discharged from the hospital the next day. The laboratory report of his gastric washings showed copper salts, and the attending physician attributed the illness to poisoning from copper salts.

Case 4. J. H. Fritz of the Kansas City (Mo.) Health Department investigated illness of a 2-year-old girl which occurred on February 18,

Dr. Hopper is chairman, department of public health, and Mr. Adams is director, sanitary science course, Indiana University School of Medicine, Indianapolis.

1957, near the city. The child became ill and vomited 15 minutes after drinking part of a carbonated beverage. The remainder of the beverage was taken by the child's grandfather to the city health department. Since the alleged poisoning occurred beyond the jurisdiction of the city health department, the laboratory of the Federal Food and Drug Administration was asked to analyze the sample. The laboratory found approximately 35 ppm copper. Investigation showed that a rubber check valve leaked and allowed carbonated water to lie in a copper waterline overnight. The first few drinks vended the following morning caused illness in eight persons, but only one sample of the beverage was available for analysis. Maintenance men from the company owning the machine replaced a faulty check valve before the Kansas City (Mo.) Health Department personnel arrived on the scene.

Case 5. The Los Angeles Health Department reported that two persons experienced nausea and vomiting within 15 minutes after drinking a carbonated beverage from a vending machine. Investigators found that a defective carbonator valve permitted carbon dioxide to back up into a copper waterline. Chemical analysis of the water from the carbonator indicated 260 ppm of copper (1).

Correspondence with the Los Angeles Health Department revealed that the check valve in question had a single ball held in place by a spring. A small particle which appeared to be a piece of a gasket had lodged under the ball preventing it from closing. A drink drawn from the machine contained 110 ppm copper, while water taken directly from the carbonator contained 260 ppm copper.

Toxicity of Copper

There is no single source of information on copper's toxicity. Information must be gathered from the official publications of a large group of professional agencies. Excerpts from some of these leave the impression that an exact figure for toxicity of copper in man cannot be given.

The Dispensatory of the United States of America (2) states that "copper is a constitu-

ent of all tissues of the animal organism; it is absorbed in the intestinal tract from food, which supplies about 2 mgm. daily." It is stored in the liver, and blood contains about 0.14 mg. per 100 ml., or 1.4 ppm. The possible deleterious effect of continued ingestion of considerable quantities of copper has been debated. Copper is not toxic in the same sense that lead, mercury, and nickel are toxic. Many of the soluble salts of copper when taken in a large quantity may give rise to gastroenteritis. The phrase "large quantity" is not defined. Vomiting is usually so prompt that systemic poisoning does not occur.

Davenport (3) in an excellent review states that "there seems to have been, and still is for that matter, no unanimity of opinion regarding the toxicity of copper." She quotes from an editorial (4) on copper which said: "The danger from copper waterlines is slight. Copper is readily attacked by the various acids present in foods such as acetic, citric, malic, tartaric, and oleic. Consequently, any food or drink containing acid will dissolve a certain amount of copper if it comes in contact with that metal. There is no doubt that the human organism can take care of minute amounts of copper, but where the dividing line is between the harmless and the harmful amount cannot yet be said. Individual susceptibility probably enters in to complicate the problem. The danger from copper and brass pipes is negligible. Although copper cooking utensils might possibly be dangerous especially when used for fruits, the real risk comes from industrial hazards and from moonshine liquor."

Gleason and his co-workers state that in general the soluble ionized salts of copper are much more toxic than the insoluble or slightly dissociated compounds (5). The subacetate and the chloride forms are the most poisonous, with cuprous chloride being twice as toxic as the more common cupric salt. They go on to point out that no major toxicological distinctions are recognized between these two valences of copper. Only cupric copper was measured in our series of experiments.

Methods and Results

A post-mix type of machine was obtained on consignment to simulate field conditions for the

study (4). The other materials consisted of 3/8-inch copper tubing cut in 6-foot lengths, some valves, and a cylinder of carbon dioxide.

A 6-foot piece of copper tubing was filled with 100 ml. of carbonated water from the machine, which was connected to the building's water supply. One end of the tube was closed with a valve and the other end was connected to a cylinder of CO₂ under 75 pounds pressure. Tests were repeated 16 times for copper in tap water under pressure. Each ranged from 1 to 4 days in duration. The results varied from 0 to 10 ppm. All tests for copper were made by R. B. Forney, department of toxicology, Indiana University Medical Center, according to the diethyldithiocarbamate method (6).

Since the copper tubing was new, the inside of one tube was etched to see if it would, in this condition, release more copper. The tube was treated with 10 percent nitric acid for 20 minutes and then rinsed thoroughly. Carbonated water was used; the results were not different from those described above.

When an orange drink was used in two separate 24-hour tests, 4.4 and 7.6 ppm copper was obtained from each. At this point all results were regarded as essentially negative.

Table 1. Effect of 75 pounds of carbon dioxide static pressure on water or flavored drink in a copper tube

Number of trials	Contents of tube ¹	Length of test (days)	Copper (ppm)
16	Tap water.....	1-4	0-10
1	Tap water ²	1	0-10
1	Orange drink ³ (noncarbonated).....	1	4.4
1	Orange drink (noncarbonated).....	1	7.5
1	Orange drink (noncarbonated).....	1	5.0
1	Cola drink (carbonated).....	1	13.0
1	Cola drink (carbonated).....	4	25.0
3	Orange drink (carbonated).....	1-4	20-50
1	Orange drink (carbonated).....	4	200.0

¹ In all cases, the valve at one end of the copper tube was closed. The other end was connected to a cylinder of carbon dioxide.

² The tube was treated with 10 percent nitric acid for 20 minutes before using.

³ The term "noncarbonated" means that the water for the drink did not pass through the carbonator in the machine.

The syrup lines are not connected to the waterline in post-mix machines. Hence a vended drink cannot back up into the waterline in the event of a check valve's failure. Despite this, an orange drink and a cola drink, made with 1 ounce of syrup and 5 ounces of carbonated water, were each kept in a copper tube for 24 hours under 75 pounds CO₂ pressure. The laboratory of the Indiana State Board of Health analyzed these samples in order to check on the previous work and reported that the orange drink contained 5.0 ppm copper and the cola drink 13 ppm copper, which approximated the amount we had obtained. Water under similar conditions showed 6.0 ppm copper.

For the next experiment a cola drink was put into the tube and held under 75 pounds CO₂ pressure for 4 days. The pH was 4.0 when the drink was removed, and it contained 25 ppm copper. An orange drink treated similarly had a pH of 3.5 and 200 ppm copper. Drinks not treated with CO₂ had a pH of 2.0 and less than 1 ppm copper. Carbonated water held for 4 days under 75 pounds pressure at pH 5.2 had 2 ppm copper. Repeated attempts ranging from 1-4 days with the orange drink gave copper in amounts of 20 to 50 ppm. As the summary in table 1 indicates copper was found in the acid drink that was allowed to stand in the tube. But the cause, we reason, could be due to either the acidity or to the type of drink. As a result, buffers were made to check on the effect of acidity.

Buffers were prepared according to Clark's method (7). Their pH varied from 2.6 to 5.0. Potassium acid phthalate and hydrochloric acid up to pH 3.6 were used in the preparation; the phthalate with sodium hydroxide added was used for pH 4.0 to 5.0. The tube was filled with buffer at pH 3.35 and kept at room temperature for 24 hours. No CO₂ was used. When the buffer was removed, its pH was 3.90 and it contained 200 ppm copper. A repeat experiment showed 166 ppm copper. In the next trial CO₂ was bubbled through carbonated water at pH 5.6 for 18 hours. The result was 3.5 ppm copper. However, when the pH was reduced to 5.0 and CO₂ was bubbled through the water for only 2 hours, the result was 25 ppm copper.

We thought that the amount of copper dissolved might be dependent upon whether the tube was new or old. A new tube was filled with buffer at pH 3.60 and was allowed to stand at room temperature for 21 hours. When the buffer was removed, its pH was 3.90 and it contained 600 ppm copper. For an old copper tube, we used the tube which had been etched with nitric acid some months previously and which had been used repeatedly. Buffer at pH 4.75 was put into this tube and kept at room temperature for 20 hours. When the buffer was removed, its pH was 4.80 and it contained 500 ppm copper. Thus, the age of the tube seemed to have no effect.

Table 2. Effect of pH on copper tube

Buffer (pH)	Time (hours)	Copper (ppm)
3.35-----	24	¹ 200
3.50-3.90-----	24	¹ 166
5.6-----	18	² 3.5
3.60-----	21	² 600
5.0-----	2	² 25
4.75-----	20	² 500
4.0-----	2	² 400

¹ No CO₂ was used.

² CO₂ allowed to bubble through the tube.

It appeared at this point that copper would dissolve if CO₂ were bubbled through the water at a high enough rate to reduce the pH below 5.0. This reduction was easily accomplished. Carbon dioxide was bubbled through the water until the pH was 4.0 and the amount of copper was 400 ppm (see table 2).

At a pH below 5.0 using a phthalate buffer, large amounts of copper were dissolved. Tap water in a copper tube with CO₂ bubbling through it gave similar results. Thus, it was obvious that copper dissolves as the acidity increases. This lowering of pH occurs when CO₂ bubbles continuously through a copper tube containing water, and is similar to what happens when a faulty check valve is under CO₂ pressure higher than the water pressure.

The explanation for the phenomena reported remains obscure. In all probability the copper which is dissolved is not directly related to the pH, since a very strong acid is needed to

dissolve copper. It would seem that the solubility of copper is dependent upon the presence of dissolved oxygen as well as carbon dioxide. There is ample dissolved oxygen in tap water to form an oxide of copper, which, in the presence of carbonic acid, gives enough copper ions to combine with naturally occurring sulfates and carbonates to appear in the vended drink. A faulty check valve permits carbon dioxide to bubble through the tube and allows enough circulation of water to supply the oxygen needed for the first step in the process.

Public Health Aspects

At the outset, it should be understood that copper poisoning does not represent a public health problem of any great magnitude, since the relatively few cases on record compared with the millions of soft drinks consumed would give an infinitesimally small case rate. To minimize copper poisoning, however, we suggest:

1. Vending machines should adhere to the sanitation code concerning the use of two check valves or a double check valve; or an air gap; or a device to vent the CO₂ to the atmosphere; or a device approved by the health authority (8).

2. A carbonator should not be made of copper. It should be made of an acid resistant nontoxic metal.

3. Water filters and water conditioning devices should not use a copper container.

Summary

If the check valves in a post-mix type vending machine do not function correctly, carbon dioxide may enter the water supply line. In the event that this line is made of copper, then (a) the CO₂ or carbonated water will react with the copper; (b) under certain conditions, the quantities of copper going into solution could be quite large; and (c) copper poisoning could occur from a beverage dispensed from a post-mix type, carbonated beverage machine.

Support is thus given to recommendations that these machines be designed and constructed so as to preclude contact between copper and CO₂ or carbonated water, and such machines be

study (4). The other materials consisted of 3/8-inch copper tubing cut in 6-foot lengths, some valves, and a cylinder of carbon dioxide.

A 6-foot piece of copper tubing was filled with 100 ml. of carbonated water from the machine, which was connected to the building's water supply. One end of the tube was closed with a valve and the other end was connected to a cylinder of CO₂ under 75 pounds pressure. Tests were repeated 16 times for copper in tap water under pressure. Each ranged from 1 to 4 days in duration. The results varied from 0 to 10 ppm. All tests for copper were made by R. B. Forney, department of toxicology, Indiana University Medical Center, according to the diethyldithiocarbamate method (6).

Since the copper tubing was new, the inside of one tube was etched to see if it would, in this condition, release more copper. The tube was treated with 10 percent nitric acid for 20 minutes and then rinsed thoroughly. Carbonated water was used; the results were not different from those described above.

When an orange drink was used in two separate 24-hour tests, 4.4 and 7.6 ppm copper was obtained from each. At this point all results were regarded as essentially negative.

Table 1. Effect of 75 pounds of carbon dioxide static pressure on water or flavored drink in a copper tube

Number of trials	Contents of tube ¹	Length of test (days)	Copper (ppm)
16	Tap water.....	1-4	0-10
1	Tap water ²	1	0-10
1	Orange drink ³ (noncarbonated).....	1	4.4
1	Orange drink (noncarbonated).....	1	7.5
1	Orange drink (noncarbonated).....	1	5.0
1	Cola drink (carbonated).....	1	13.0
1	Cola drink (carbonated).....	4	25.0
3	Orange drink (carbonated).....	1-4	20-50
1	Orange drink (carbonated).....	4	200.0

¹ In all cases, the valve at one end of the copper tube was closed. The other end was connected to a cylinder of carbon dioxide.

² The tube was treated with 10 percent nitric acid for 20 minutes before using.

³ The term "noncarbonated" means that the water for the drink did not pass through the carbonator in the machine.

The syrup lines are not connected to the waterline in post-mix machines. Hence a vended drink cannot back up into the waterline in the event of a check valve's failure. Despite this, an orange drink and a cola drink, made with 1 ounce of syrup and 5 ounces of carbonated water, were each kept in a copper tube for 24 hours under 75 pounds CO₂ pressure. The laboratory of the Indiana State Board of Health analyzed these samples in order to check on the previous work and reported that the orange drink contained 5.0 ppm copper and the cola drink 13 ppm copper, which approximated the amount we had obtained. Water under similar conditions showed 6.0 ppm copper.

For the next experiment a cola drink was put into the tube and held under 75 pounds CO₂ pressure for 4 days. The pH was 4.0 when the drink was removed, and it contained 25 ppm copper. An orange drink treated similarly had a pH of 3.5 and 200 ppm copper. Drinks not treated with CO₂ had a pH of 2.0 and less than 1 ppm copper. Carbonated water held for 4 days under 75 pounds pressure at pH 5.2 had 2 ppm copper. Repeated attempts ranging from 1-4 days with the orange drink gave copper in amounts of 20 to 50 ppm. As the summary in table 1 indicates copper was found in the acid drink that was allowed to stand in the tube. But the cause, we reason, could be due to either the acidity or to the type of drink. As a result, buffers were made to check on the effect of acidity.

Buffers were prepared according to Clark's method (7). Their pH varied from 2.6 to 5.0. Potassium acid phthalate and hydrochloric acid up to pH 3.6 were used in the preparation; the phthalate with sodium hydroxide added was used for pH 4.0 to 5.0. The tube was filled with buffer at pH 3.35 and kept at room temperature for 24 hours. No CO₂ was used. When the buffer was removed, its pH was 3.90 and it contained 200 ppm copper. A repeat experiment showed 166 ppm copper. In the next trial CO₂ was bubbled through carbonated water at pH 5.6 for 18 hours. The result was 3.5 ppm copper. However, when the pH was reduced to 5.0 and CO₂ was bubbled through the water for only 2 hours, the result was 25 ppm copper.

Miss Sleeper

Dr. Dearing

Mr. Mason

Dr. Arnold

New Members of the PHR Board of Editors

The Board of Editors of *Public Health Reports* has gained four new members. Appointed to the board for 3 years, they replace outgoing members Dr. Leo W. Simmons, Dr. H. Trendley Dean, Margaret Arnstein, and Vernon G. MacKenzie.

Francis A. Arnold, Jr., D.D.S., became director of the National Institute of Dental Research, Public Health Service, in 1953. He had served as associate director since establishment of the institute in 1948.

Dr. Arnold's entire professional career has been in the Public Health Service, which he entered in 1934 on graduation from the dental school of Western Reserve University. In 1937, he joined the Dental Research Section, National Institutes of Health, of which he became assistant chief in 1943.

A prolific researcher of international eminence in the dental sciences, Dr. Arnold is a fellow of both the American College of Dentists and the American Public Health Association. He is also a member of the American Dental Association and a former president of the International Association for Dental Research and is now vice president of the Fédération Dentaire Internationale.

W. Palmer Dearing, M.D., assistant director for health in the Office of Defense Mobilization, previously served for 9 years as Deputy Surgeon General of the Public Health Service.

After graduation cum laude from Harvard Medical School, Dr. Dearing taught epidemiology in the Harvard School of Public Health. He became a Public Health Service career officer in 1934, serving as an epidemiologist in studies of poliomyelitis and tuberculosis until 1941. That year he was assigned to the Office of Civilian Defense as assistant, and then, chief medical officer. In 1944 he was named personnel chief of the Health Division, United Nations Relief and Rehabilitation Administration, returning to the Public Health Service in 1945 as deputy chief of the Division of Public Health Methods. A year later he became chief of the Division of Commissioned Officers.

Karl M. Mason, M.P.H., was named director of the bureau of environmental health, Pennsylvania Department of Health, in 1954, after having served as the

department's director of professional training since 1951. During 1949 to 1951, he was associated with the Public Health Service following 6 years as director of the division of public health engineering with the Peoria, Ill., Department of Health. Previously, he spent 2 years as public health engineer with two county departments of health in Michigan.

Mr. Mason is a diplomate of the American Academy of Sanitary Engineers and a member of the Advisory Committee to the Surgeon General of the Public Health Service on Water Pollution Control. In addition, he is the Pennsylvania representative on the governing council of the American Public Health Association and a lecturer at both the University of Pittsburgh Graduate School of Public Health and the Robert A. Taft Sanitary Engineering Center in Cincinnati, Ohio.

Ruth Sleeper, R.N., has been director of the School of Nursing and Nursing Service of the Massachusetts General Hospital in Boston since 1946. She began her nursing career in 1922 when she graduated from the Massachusetts General Hospital Training School for Nurses. Miss Sleeper took a master of arts degree from Teachers College, Columbia University, in 1935 and holds the honorary degrees of doctor of humanities from Boston University (1953) and doctor of science from Hood College (1954).

President of the National League of Nursing Education during 1944-48 and of the National League of Nursing in 1952-55, she was also chairman of the Joint Commission for the Improvement of the Care of the Patient.

Her current posts include chairmanship of the Education Committee of the International Council of Nurses and membership on the Expert Committee on Nursing of the World Health Organization and on the Board of Directors of the National League of Nursing.

equipped with a device or devices that provide positive protection against the backflow of CO₂ or carbonated water into the building water supply system.

National Conference on Air Pollution

Municipal, county, and State health personnel, control officials, and scientists and technicians concerned with atmospheric pollution will meet with community leaders representing a wide variety of civic, industrial, and service organizations and agencies at the National Conference on Air Pollution in Washington, D. C., November 18-20, 1958.

Surgeon General Leroy E. Burney has called this conference, open to anyone interested in the subject, for two principal purposes: to create a wider understanding of air pollution problems among civic leaders, and to outline a practicable plan for future action in both research and control.

The program is designed to encourage maximum participation by all conferees. Following a day of orientation, during which participants will hear a status report from the Surgeon General and brief presentations on current knowledge and accomplishments, the assembly will divide into six discussion groups to formulate recommendations for desirable future activities.

On the morning of the third day, the six groups will present their recommendations to a plenary session. The final afternoon's pro-

gram will resemble a "town meeting," with questions and discussion from the floor.

A steering committee comprising representatives of the American Public Health Association, American Municipal Association, Air Pollution Control Association, and other principal governmental, industrial, and scientific organizations have aided the Surgeon General and his staff in planning the conference.

Chairmen and vice chairmen of the discussion groups, in that order, are as follows:

Extent of air pollution: Dr. Arie J. Haagen-Smit and Dr. H. C. McKee.

Sources of air pollution: S. L. Hanauer and Dr. Leslie Chambers.

Health effects of air pollution: Dr. Malcolm H. Merrill and Dr. James P. Dixon.

Economic and social effects of air pollution: Dr. John T. Middleton and Arthur Crago.

Control methods and procedures for air pollution: Dr. Leslie Silverman and W. C. L. Hemeon.

Administrative aspects of air pollution: Dr. Louis C. McCabe and Harold W. Kennedy.

ing programs in public health education. The sequence of events is best reflected in a review of the years when students in public health education were first enrolled in other schools of public health.

1945—University of Minnesota

1946—North Carolina College

1946—University of California

1948—University of Puerto Rico

1951—Harvard University

1951—Columbia University

All these schools are still training public health educators. Consequently, since 1943 the number of academically trained health education personnel in the United States has increased. In contrast to 1943, when 7 students were enrolled in public health education training, in 1958 the enrollment in schools of public health showed a total of 130 students. In addition to the students currently in training, reports indicate that approximately 1,250 persons have received academic training at the graduate level in public health education from 1943 through 1957. This total includes students in Puerto Rico, but does not include students from foreign countries.

Several additional results are also evident. When the Kellogg funds were expended, other agencies, both voluntary and official, began to support health education training. This trend has continued; 60 percent of the students enrolled in courses of public health education for the school year 1956-57 were sponsored either by official or voluntary agencies.

Schools which now provide training at the doctorate level are the University of California, Harvard University, and the University of North Carolina.

Increasingly for the past 10 years, schools have made their courses available to students from other countries. In many instances special training has been arranged for these students, whose needs differ radically from those of Americans.

Health Leadership

Health leadership both in this country and on the international scene has come from among the candidates who studied under the Kellogg Foundation Fellowships. The positions which

the fellows currently hold reflect the impact of the fellowships that were awarded from the two grants.

For this phase of the report the graduates were asked to submit a summary of their professional activities since the completion of their health education training. The questions were open-ended; consequently, there is not complete uniformity in the responses. Nevertheless, all the data received are included in this summary.

In March 1958, data were obtained on 38 of the 47 candidates. Of the other 9, 1 is deceased, 1 entered a religious convent and no information is available as to whether she worked previously in public health, 4 persons did not respond to the letter of inquiry, and 3 could not be located. Of the 38 candidates who responded to the letter of inquiry, 24 received their training at the University of North Carolina, 7 at the University of Michigan, and 7 at Yale University. Three of them have since taken further graduate work and obtained doctorates of philosophy, and a fourth is currently enrolled in a course leading to the doctorate degree.

Following completion of the training, 37 of the 38 did work as health educators for varying periods of time. Employment in health education ranged from less than 1 to 15 years with a median of $7\frac{1}{2}$ years. The one candidate who did not work in this capacity married immediately following graduation, and although she did work for 6 months on a health project, it was not as a health educator. Currently, 22 of the 38 respondents are employed, 18 in health education positions and 4 in other fields.

Since all fellowships were awarded to women, marriage could be expected to remove a large portion of them from the labor market. Twenty-five have married, and they have usually withdrawn from employment at the time of marriage. However, several have returned to work after varying periods of absence. As a group they have worked in health education from less than 1 to $11\frac{1}{4}$ years with a median of $3\frac{3}{4}$ years. Currently 9 are employed: 5 in health education positions, 3 in teaching, and 1 as a laboratory technician.

Several of the respondents indicated they hope to return to active employment when their

History of a Health Education Fellowship Program

IDA BRUGNETTI, M.P.H., and MAYHEW DERRYBERRY, Ph.D.

ACADEMIC TRAINING specifically in public health education prior to 1943 was received by relatively few. In 1943 the two schools offering such training, Yale University and the University of Michigan, had only seven students enrolled.

A demonstration project had been started under the sponsorship of the Public Health Service in 1941 in North Carolina. Its purpose was to demonstrate what a person trained in health education could contribute to the achievement of the goals of a public health program. By 1943, this demonstration led to a proposal to train more such personnel. As a result of a request from the Public Health Service, the W. K. Kellogg Foundation made two grants totaling \$72,000 for the purpose "of increasing the number of qualified public health education personnel in the United States who could carry on the types of health education programs that had been demonstrated as being successful in North Carolina."

The steps developed to accomplish this purpose were:

1. To initiate a program for the training of public health educators in the University of North Carolina.
2. To stimulate and support programs of training then in existence at Yale University and the University of Michigan.
3. To encourage other schools of public health to establish training programs in health education.

This report, prepared 15 years after the initial grant, supplements previous summary reports of the program and describes some of the results.

Miss Brugnetti is a health education consultant assigned to the Illinois State Health Department, and Dr. Derryberry is chief of the Public Health Education Branch, Division of General Health Services, Bureau of State Services, Public Health Service.

To initiate the training of public health educators at the University of North Carolina it was decided to award fellowships directly to qualified individuals for a 1-year graduate course in public health education leading to the degree of master of public health. To be eligible candidates were required to have a baccalaureate degree which included a background in the natural sciences and social sciences. Preference was given those who had shown some degree of effective participation in community undertakings and who displayed skill in and an understanding of human relations.

For the majority of candidates, the fellowships completely financed their training, paying for tuition, field training, travel, and a monthly stipend to the individual. Others were awarded partial fellowships which paid only a portion of their expenses.

Extending the Program

In its second phase, the program was extended to Yale University and the University of Michigan. The two grants provided a total of 47 fellowships, 41 completely financed and 6 partially financed. Of these, 26 went to the University of North Carolina; 11 to the University of Michigan; 10 to Yale University. All the awards were to women, inasmuch as during the war men were not exempted from military or other essential employment to study specialties such as health education.

The program of study initiated in the University of North Carolina, with progressive modifications to meet the changing demands, is still operating. It has continued to develop, offering courses at the doctorate level, and since 1946, has been extended to North Carolina College.

Recruitment, training, and placement of the candidates who had completed specialized study in public health education helped to encourage other schools of public health to establish train-

The New York State Interdepartmental Health Resources Board enables State agencies concerned with physical and mental health to achieve concerted action.

An Interdepartmental Approach to Health

I. JAY BRIGHTMAN, M.D.

SEVERAL UNITS of government are concerned with health and medical care. Departments of health, as well as mental health agencies and hospitals that are organized as separate government units, are primarily responsible. Departments devoted to social welfare, education, correction, and labor (including workmen's compensation) also have as a secondary function a share in health matters.

Very often the health functions of these departments are closely related or identical, the difference being limited to the population groups served by the specific agencies, the nature of the health matters coming under their jurisdictions, and the professional disciplines available to them. Cooperation among the departments and coordination of their efforts are necessary if unbalanced or conflicting approaches are to be avoided and effective programming achieved.

The New York State Interdepartmental Health Resources Board was established by an act of the 1956 State legislature to permit joint planning, coordination, and program development of physical and mental health matters that concern two or more State departments or agencies.

In an editorial comment on the development of the board, Dr. Herman E. Hilleboe, New York State's commissioner of health, stated:

Dr. Brightman is executive director of the New York State Interdepartmental Health Resources Board, Albany, N. Y.

"In an era when it would appear that governmental agencies are ever expanding, it is heartening to note the establishment of the Interdepartmental Health Resources Board which actually replaces two former health units of New York State government. The establishment of this board is a step forward in efficiency and economy in government affairs in the field of human resources" (1).

The replaced health units to which Dr. Hilleboe referred were the Interdepartmental Health Council and the Mental Health Commission. The council, organized in 1947 on a directive from the Governor, included the commissioners of health, education, social welfare, and mental hygiene, and a member of the State legislature. The council met monthly to study problems in public health of interest to the several departments in order to determine the extent to which the State programs were meeting their objectives, and to make recommendations accordingly. It performed a useful service in the exchange of information and ideas on departmental activities in various health fields and in conducting special studies through interdepartmental committees. Since the council was not established by a legislative act as an executive agency, however, it had no official status. It received no funds of its own and could neither employ a full-time staff nor contract with outside agencies for special projects. Its limited staff work was carried out by the executive director of another State agency, the Joint Hospital Survey and Planning Commis-

children mature. Another factor possibly influencing the employment of married women is their place of residence. The women who listed teaching as their current work are residing in small towns where positions in health education may not exist. However, no data are available regarding this point or the preference for teaching school by the graduates.

Of the 13 respondents who are not married, all appear to have worked in health education since their graduation and are still working in a variety of types of agencies and positions. The length of such employment has varied from 9 to 14½ years with a median of 12½ years. The positions these graduates hold are:

Consultants for State boards of health: 3.

Consultants in the International Cooperation Administration, serving ministries of health in other countries: 2.

Consultants in the Indian Health program of the Public Health Service: 2.

Consultant in the National Tuberculosis Association: 1.

Health educators in Public Health Service regional offices: 2.

Faculty member of a school of public health in a State university: 1.

Professor of health education in a State university: 1.

Supervisor of health and physical education in a State department of public instruction: 1.

Fourteen respondents provided the unsolicited information that, although they were not currently in paid employment as health educators, they had participated as volunteers in a wide variety of health programs. These activities included:

Organizing the city for a poliomyelitis drive.
Serving on the American Red Cross health committee.

Chairing the health committee of the community chest.

Working with citizens groups to improve the State's public health laws.

Member of board of directors of the mental health society.

Member of board of directors of a tuberculosis association.

Teaching mothers' classes in the town's nursing service.

President of a State education association.

Committee member of the maternal health association.

Chairman of the YWCA health committee.

Member of the Committee on Local Resources of the League of Women Voters.

Health chairman of a parent-teacher association.

Education director of the citywide X-ray survey.

Member of the executive committee of a tuberculosis and health association.

Secretary of a community health council.

Member of the national board of YWCA.

Member of a local council of Girl Scouts of America.

Summary

The fellowship program of the W. K. Kellogg Foundation financed the training of 47 public health educators and stimulated the expansion of such training for more than a thousand others. Today, 15 years after the awarding of the first fellowship, a review of the professional activities of 38 of the 47 candidates who were awarded fellowships finds many of them in responsible positions in the public health field.

error's office. In 1957, there was considerable pressure upon the State legislature and the Governor's office to license chiropractors in New York State. The Governor's office, aware that several State departments would be affected by such legislation, requested the board to study the matter. In another instance, after the Governor's conference on financing health costs for the aging in December 1956, the recommendations made by the three sections of the conference were referred to the board by the Governor's special assistant on problems of the aging for analysis and recommendations.

5. Special projects accepted by the board after its consideration of suggestions referred by outside agencies, such as the request of the State medical society for a study of the standards for orthoptic technicians working under the supervision of ophthalmologists.

6. Special projects accepted by the board upon consideration of recommendations made by one of its members, by its executive director, or by one of its advisory committees. For example, the commissioner of education, a member of the board, requested that the board undertake a study of the problem of "baby nurses," a term used for women who have taken courses in maternity and infant care at unlicensed schools. Although possible violations of the Nurse Practice Act were involved, the problem was referred to the board on the basis that it was of equal concern to the departments of health, social welfare, and education.

In planning its work, the board believes that its activities in joint planning and program development should continue as long as such activities are considered by the board members to be productive and beneficial. However, in accord with the philosophy underlying the board's establishment, research and demonstration projects must either be self-limited or be transferable to an appropriate permanent State administrative agency at a feasible time. The board is not to engage in long-term operating activities on any one particular program.

Methods of Operation

The functions of the board are carried out through one or more of the following methods:

By direct operations of the board's staff. Obviously the small size of the board's staff, with 4 of the 7 persons in nonprofessional grades, would curtail the board's activities if the staff was its only outlet for operations. The staff is the board's working arm and is responsible for initiating all of its functions. However, a considerable part of its work is done through the arrangements described in the remaining paragraphs of this section.

Through the operations of special board committees. For each major function undertaken by the board, there is a board committee whose individual members are experts from various disciplines and are appointed by the commissioners concerned with the problem at hand. The committees meet regularly with the executive director, assist in planning and developing projects, and put at the disposal of the director and board the required facilities and services of their respective departments.

Through advisory committees in special fields. The advisory committees meet about four times yearly and consist of experts in their respective fields, not associated with government. Their responsibility is to recommend new areas for exploration and to explain the board's functions and projects to appropriate professional groups and to the public.

By contracts with universities, medical schools, or hospitals. These agree to undertake special studies with financial assistance obtained by the board. In this way, the board has been able to carry out several major research projects on mental retardation and mental illness among children and on chronic alcoholism.

By joint studies with professional associations and voluntary health agencies. For example, the board is cooperating with the Hospital Association of New York State in a study of admission of chronic alcoholics to hospitals. The study of orthoptic technicians, referred to above, was a joint undertaking with the New York State Medical Society.

Examples of Activities

From the beginning, it was evident that one important aspect of the board's operations applies to all activities and is requisite to the

sion, who generously and effectively contributed whatever time he could spare from his very busy schedule.

The Mental Health Commission was formed by a legislative act in 1949 and included as members the commissioners on the Interdepartmental Health Council, plus the commissioner of correction. The commission had a full-time staff of administrators and research workers, and it was able to develop several major research projects in the field of mental illness and mental retardation. It also developed the basic groundwork upon which the New York State community mental health services program was established in 1954.

It was the unanimous decision of all commissioners concerned that interdepartmental work in both physical and mental health could be more effectively implemented and developed through a single, organized State agency. Their recommendations to this effect were accepted by the Governor and the necessary legislation was passed to establish the Interdepartmental Health Resources Board on April 1, 1956, for a period of 4 years.

Organization

The membership of the Interdepartmental Health Resources Board includes the commissioners of health, mental hygiene, education, social welfare, labor, and correction, the chairman of the Division of Parole and of the Workmen's Compensation Board, and the executive director of the Joint Hospital Survey and Planning Commission.

A chairman is elected annually by a vote of the members, with no member serving in this capacity for more than 1 year at a time. The commissioner of mental hygiene, Dr. Paul H. Hoch, served as chairman during the first year. He was succeeded by the commissioner of social welfare, Raymond W. Houston.

The board is responsible to the Governor and the State legislature and must submit to them an annual report of its activities and such recommendations as it may deem appropriate.

The legislation empowered the board to employ an executive director with the responsibility of carrying out its administrative duties in accordance with its established policies,

rules, and principles. After considering the responsibilities of the executive director, the board decided during its early meetings that the position could best be filled by a physician with training in public health and with considerable administrative experience. At the present time, the executive director is assisted by a staff consisting of a nonmedical assistant director trained in public health administration, a biostatistician, a secretary, a stenographer, a typist, and an account clerk. In addition, the board is authorized to request assistance from any member, department, or agency that will enable the board to carry out its activities properly.

Determination of Assignments

The general objectives of the Interdepartmental Health Resources Board are (a) to provide for joint planning and program development in health matters of interdepartmental concern, and (b) to formulate and execute research studies and demonstration program that will provide the board and member agencies with information and guidance for long term planning.

Specific projects may come under the board's jurisdiction through several channels which may be classified as follows:

1. Functions specifically designated by the 1956 legislative act which established the board. This act outlined projects which might be undertaken in health services for the aging, rehabilitation, mental retardation, services for emotionally disturbed children, and alcoholism.

2. Functions specifically assigned the board by other legislation. For example, an act passed by the 1956 session of the State legislature gave the board, as successor of the Mental Health Commission, responsibility for establishing pilot centers for diagnosing mental retardation in children and counseling parents.

3. Functions assigned by special budgetary appropriations to the board. In the 1956 State budget, the establishment of a pilot facility for adults addicted to narcotics was delegated to the board when the latter became functional.

4. Special studies requested from the Gov-

rehabilitation services and to develop a mechanism whereby such services may be received.

Also under study is the care of young adults who have no potentialities for further rehabilitation, who are unable to provide care for themselves, and who cannot be suitably placed in infirmaries or nursing homes because of the predominantly elderly population of these institutions.

Aging

The legislative act on aging which founded the Interdepartmental Health Resources Board requested it to develop and formulate "a master plan for establishing responsibility for planning, financing, administering, and coordinating the total array of personal health and mental health services to the elderly." Based on its review of reference materials, plus its evaluation of the current State and local programs, the board's Committee on Health Services for the Aging analyzed (a) the specific mental and physical health needs of the aged, (b) the resources available in the State to meet these needs, (c) the deficiencies in meeting these needs, and (d) recommendations for overcoming the deficiencies.

The board drew this material together as a planning guide for the executive office and the State legislature.

Retarded and Disturbed Children

The board has established three pilot clinics to provide diagnostic services for mentally retarded children and counseling for their parents. It is also studying these clinics and similar facilities to determine their role in meeting community needs. In addition, several research projects have been completed or are underway on such matters as the adjustment of the severely retarded adult in the community, the preinstitutional workup of the mentally retarded person entering State schools, and the psychological and social development of children in classes for the severely mentally retarded.

A major study is being completed on characteristics of emotionally disturbed children referred to residential treatment centers. A similar study is underway on children referred to day-care centers.

Alcoholism

The board supports a major research center on alcoholism at the State University College of Medicine in Brooklyn. It expects that the findings here may be used in clinics throughout the State. In addition, the board has established a training program for persons in various disciplines who are engaged in or plan to engage in community control of alcoholism. For the development of clinics at the community level, the board is working closely with the division of community mental health services of the department of mental hygiene. At present, the board's Advisory Committee on Alcoholism is studying the State program in order to develop a more comprehensive approach.

Discussion

With its year and a half of operating experience, the New York State Interdepartmental Health Resources Board has effectively achieved interdepartmental cooperation, planning, and program development. With a full-time staff and the authority bestowed upon it by the State legislature, the board has made a positive approach to complex health problems involving several State departments and often many other agencies, and has formulated recommendations based on the accumulation of pertinent information and the exercise of sound deliberations.

The board's monthly meetings have permitted the functioning of its staff and of the committees and agencies working with that staff to be reviewed, and have resulted in a stimulating exchange of opinions on matters of joint and mutual concern. Matters of particular urgency may be taken up at any time through special meetings of an executive committee consisting of the commissioners of education, health, mental hygiene, and social welfare. Of particular importance, for example, may be legislative proposals concerning two or more departments. A comprehensive understanding, gained through discussion of the effect that the proposed legislation may have upon all the State's health programs, may lead to concerted action. This is in contrast to a multiplicity of conflicting approaches which

board's proper functioning in joint studies, planning, and program development. The board obviously offers an organized means of exchanging information among the member agencies on their specific health problems, on their individual philosophies and policies, and on the development of new programs which may be related to, and may serve or be served by, the operations in other agencies.

This function applies equally to the regular board meetings attended by the commissioners and agency directors and to the meetings of the special interdepartmental committees.

The major activities of the board encompass the fields of rehabilitation, aging, mental retardation, emotional disturbances in children, and alcoholism.

Rehabilitation

The committee advises the Joint Hospital Survey and Planning Commission on the construction of rehabilitation facilities.

Projects developed by the division of vocational rehabilitation of the State education department are considered by the committee in relation to the needs and resources of the projects.

The committee is offering technical guidance to the rehabilitation survey of the workmen's compensation program.

A subcommittee served on a joint advisory committee for the northern New York rural rehabilitation survey which was completed during the summer of 1957. This was a joint effort of the Saranac Lake Rehabilitation Guild, the State University College of Medicine at Syracuse, and the New York State Department of Health. Because of the project's interdepartmental nature, the commissioner of health requested the committee on rehabilitation of the former Interdepartmental Health Council to represent it on the advisory committee. This function was carried over when the board was established.

The purpose of this survey was to identify disabled persons in the northern New York rural area, to determine their needs in relation to vocational goals or increased self-sufficiency, and to determine the necessary facilities and personnel required to meet these needs. The subcommittee representing the State in this

project included the assistant commissioner for vocational rehabilitation and the director of the division of vocational rehabilitation of the State education department, the assistant commissioner for medical services of the State department of health, the executive director of the Joint Hospital Survey and Planning Commission, and the executive director of the Interdepartmental Health Resources Board.

The committee is currently engaged in a study of job vacancies in rehabilitation, including physical, occupational, and speech therapy, clinical psychology, rehabilitation counseling, and medical and psychiatric social work. In this connection, it is working with the New York State Department of Civil Service and is attempting to define the factors which make it possible to fill some positions while other positions remain vacant. The committee offers a booklet on scholarships available to residents of New York State in rehabilitation work. This booklet has been distributed to rehabilitation facilities, medical schools, hospitals, and voluntary agencies throughout the State.

Recognizing a lack of knowledge and understanding of the services for epileptics in New York State, the committee published a statement in the *New York State Journal of Medicine* outlining the services available in vocational rehabilitation, selective placement, health, and mental hygiene, and put reprints at the disposal of rehabilitation medical facilities throughout the State.

The committee is analyzing the objective of sheltered workshops operating in New York State as well as the extent to which such objectives are being met, the cost of operation, and the methods employed. The committee is also seeking to determine what will be needed to expand this important service.

Realizing that a large number of disabled persons are not receiving services, the committee is studying the extent of State rehabilitation services and the possibility of their expansion.

At the request of the commissioner of correction, the committee is examining disabilities in State correctional institutions, with Attica Prison and Elmira Reformatory serving as pilot studies. The purposes are to determine the extent to which disabled inmates require

Guidelines

for

the

Health

Administrator

JAMES R. SHAW, M.D.

The following is, in essence, the text of a memorandum written by Dr. Shaw, who is chief of the Division of Indian Health, Public Health Service, on the subject of basic considerations in health administration. Although the piece was composed specifically to guide new medical officers in charge of Indian health installations, health administrators in all fields may find that its philosophy strikes a resonant chord for them.

THE SUCCESS of any health operation depends in large measure upon the first impression it registers with the patient and his family on their initial contact with its employees. These first impressions set the pattern for future interpretations; they determine the lasting concepts of the operation formed by individual patients and the public generally. Hospitals and clinics take on personalities that are just as distinctive as those of any physician, nurse, or other staff member. The hospital personality, however, is the product of all of the personal traits of those who make up its human element.

Patients and visitors—adult or child, literate or unlettered, of the dominant culture or of a minority group—inevitably sense the underlying attitudes and motives which give the hos-

pital its personality. This consciousness does not require that they understand the professional terms, techniques, and procedures used in their behalf—or even that they understand simple English. But they feel and respond to a general spirit of warmth and sympathy, of understanding and support, when this is offered as the foundation of assistance.

A physician always will need assistance in the performance of his duties; around these duties all of the other activities of the hospital, clinic, office, or field program revolve to lend support. The physician must realize that his success does not depend entirely upon his own actions and ability. His success also depends in part upon the actions and abilities of others, and upon impressions made on the patient by these other individuals. The physician must never forget that he alone is responsible for the end result. Consequently, it is of the greatest importance that he be the true leader of the health team and that he accept responsibility for the personality of the health operation in the eyes of his patient, the patient's family, and the community. The public attitudes toward the operation—good or bad—will develop continuously on a progressively broader base in the direction determined by this concept of personality.

Not by Bread Alone

All of us have certain basic needs that must be met if we are to do a good job and maintain high morale. This is true of all of us—physicians, firemen, nurses, ambulance drivers, and others—and it is true regardless of remuneration received. While dissatisfaction with pay sometimes is the apparent cause of an employee's discontent and desire to change jobs, a good administrator will look first for a more probable "real" cause before considering the subject of remuneration.

Every employee must feel that the program in which he is participating is intrinsically worthwhile and that he is making a valuable contribution. Moreover, he must feel that his contribution will be recognized and appreciated. Each employee must feel that he is not at a dead end, and that progress or growth related to his work is possible within the limits of his desire and ability.

might otherwise result when departments make individual studies and take separate actions.

Obviously a pattern for interdepartmental cooperation among State agencies must be designed to meet the needs of a particular State, depending upon its laws, traditions, and resources. Several States have developed interdepartmental planning committees, of short or long duration, to tackle specific problems. Others have informal mechanisms for general exchange of information among departments. However, New York State's formal agency, with its own staff to work for regular interdepartmental cooperation and joint planning, would seem worthy of trial in other States.

The same would appear to be true of large cities or regional areas. In 1952, New York City, upon authority of the mayor's order, established an interdepartmental health council patterned after the State council then in existence and consisting of the city commissioners of health, welfare, and hospitals. The executive director of the community mental health services program has since been added. The council meets monthly; its steering committee of deputies meets weekly. While lacking a full-time staff (only a secretary for its subcommittee on aging and the secretary's stenographic aides are full-time), and being more limited in membership than the new State agency, the council has been very effective in bringing about coordinated planning and joint action.

Yet the general development of interdepartmental cooperation has been very limited at both State and local levels. In a 1956 study of cooperation between departments of health and welfare, for example, Muller and Bierman found relatively little growth during the preceding 5 years (2).

In commenting upon the problem of rehabilitation during his recent legislative message, Governor Averell Harriman made the following statement, which seems pertinent here (3):

"No phase of our total work in the conservation of human resources, as well as in combating the problem of low income, is more promising or exciting than the work of rehabilitation. Under the general coordination of the Interdepartmental Health Resources Board, created upon my recommendation 2 years ago, we have achieved a teamwork and cooperation among the various agencies concerned superior to anything that was possible before."

Health Law Center

The University of Pittsburgh has established a health law center within the Graduate School of Public Health. The law center will study the legal aspects of medicine, dentistry, nursing, public health, hospitals, and medical care. It will also be a clearinghouse for legislative and other legal materials in the health fields. In effect, the newly created health law center will be continuing and expanding services initiated under a grant from the National Institutes of Health, Public Health Service, which in 1956 provided funds for research into hospital law. Results of that study will be published in a 2-volume manual on hospital law for hospital administrators and attorneys.

bilities are sufficiently experienced to recognize that unilateral administration fails in at least two important respects. It does not provide for professional development of employees—the growth from within which insures the “organization in depth” essential for continuity in operations. It does not contribute to high employee morale, without which the operation cannot continue for long to achieve good results. Eventually, every one-man operation strikes a ceiling beyond which it cannot function satisfactorily.

Group administration requires mutual understanding of the problems, uniform direction of the program, and establishment of a common goal. Each member of the group must think not only in terms of his own specific functions but as well in terms of the relationship of his actions to common efforts to achieve the goal. Without this unity of purpose throughout the organization, its efforts will suffer.

This common approach toward clearly identified goals can be achieved with the help of frequent short meetings where frank discussion and exchange of ideas are encouraged. Such meetings, of course, should be limited to specific considerations. Subjects can be sufficiently broad to include problems of overall administration. In such meetings the administrator must direct the discussion toward the common objective, and he must draw from the participants their ideas relating to broader aspects of the program as well as to their own functions. Through this process the problems which sometimes arise in connection with jurisdictional lines will be minimized, mutual understanding will be fostered, and mutually supporting efforts will result. Many administrative problems will yield to the pooling of ideas and opinions, and others will be placed in proper perspective for further study. But equally as important, the members of the group participating will develop a real sense of teamwork. With firsthand information and broader understanding of program objectives, they will be able to make better decisions in the conduct of their own work.

This is the technique of sound health administration. It requires only a mature, understanding, and secure individual to put the process in operation.

The Good Health Administrator

A good health administrator is qualified in his profession, meticulous in his adherence to ethical practices, and possessed of high ideals and integrity. He is mature in judgment, emotionally secure, warmly human, and—in the eyes of his subordinates—understanding and helpful. The good administrator is a true leader, one who can encourage and inspire his subordinates. He makes friends readily, and he is unfailingly loyal to those who serve under him as well as to his superiors. He recognizes good work promptly, gives credit where it is due, and criticizes constructively and in private. He is both fair and firm, and he is willing to back up those who assist him in meeting program objectives. A good listener, he is able to gather all the facts upon which to act, and to act decisively and promptly without jumping to unwarranted conclusions. He has the ability to seek out the strong points in those who work under him, to cultivate these talents, and to create an environment that insures growth of his organization from within.

The good administrator never forgets that the conduct of his program is his responsibility and his alone. He recognizes that his subordinates to whom he delegates functions are helping him in carrying out his responsibility, and he earnestly appreciates their efforts. Routinely, the good administrator personally visits more or less regularly all of the areas and activities for which he is responsible. In this way he is closer to the problems, frustrations, accomplishments, and capabilities of his people. He establishes and maintains a clear-cut chain of command with properly delegated responsibility and authority. He insures that channels of communication are adequate, that they run up as well as down, and that they are adapted to the needs of the program. He establishes and maintains a fair procedure for dealing with grievances; he sees to it that this procedure is known; and he encourages its use in the interests of the employees.

This is the profile of a good administrator. The exact techniques and the specific approach will vary with the personality of the individual to whom leadership is entrusted. The principles, however, remain constant in all situations and in operations of all dimensions.

An employee has the right to expect to be consulted on matters pertaining to himself or to his position. He is entitled to reasonable leeway in adjusting to his position and responsibilities in his own way. Such a policy builds confidence and encourages initiative and acceptance of responsibility. The administrator's job satisfaction comes from the success of all, welded into a coordinated, aggressive, successful organization which shows evidence of growth from within.

Ars Medicinalis

The science of medicine continues to expand and become more exact with each passing day. However, there still exists an undiminished need for the practice of medicine as an art. In fact, the success of the scientific procedures may very well depend upon the successful practice of the art of medicine. There always will be broad vistas in the general field of medicine which have not been, and perhaps never will be, filled in by the scientific approach alone.

The practice of medicine as an art is essential because of the basic needs of patients over and beyond their requirements for the application of therapeutic agents and scientific procedures. A patient goes to a physician, or is brought to a medical facility, to get help. His need may lie in conditions which range all the way from acute illness or trauma threatening early death to a state involving no organic disease but requiring psychic support. Whatever the patient's condition may be, he and his family are seeking the physician's assistance in the solution of a problem which is of grave importance to them. Regardless of the exact nature of his problem, the patient can reasonably expect a warm, friendly, relaxed atmosphere and sympathetic understanding. He has, or he hopes to have, confidence in the advice given him so that he can make the decisions necessary for the solution of his problem.

The patient and his family expect to be consulted on all matters of importance so that they can make the necessary decisions—or at least participate in the decision making—after they have an acceptable understanding of the facts upon which the decisions must be based. The patient and his family can reasonably expect

stability and maturity on the part of the physician and his prompt attention as the circumstances warrant. They are entitled by law to the preservation of the confidentiality of personal medical information which becomes known to the physician or health facility, and they are entitled to the respect for their human dignity which is the right of all individuals in our society.

These considerations assume added importance when we remember that in acute and catastrophic illness or injury there may be some degree of self-accusation or guilt on the part of the patient, his family, or others concerned. This is particularly true when life and death hang in the balance. It may be manifested by complaints, acts of aggression, or just plain hostility. Such attitudes need never occur, or only rarely, if the basic needs of the patient and his family are met adequately in the practice of medicine as an art as well as a science.

Administration by Group

Administering a health facility or program is primarily a matter of conducting the routine activities in a way that meets the basic needs of patients, their families, and the employees.

The group method of administration is most effective in meeting these needs satisfactorily. In essence, the method permits broad participation in considerations and decisions and delegation of responsibility with commensurate authority. If the method is properly used, if the administrator makes really effective use of the potential and immediately available talent at his disposal, the administration will be sound even though the administrator himself has not had formal training or wide experience in administration. Of course, the administrator must possess personal stability and maturity and must be able to make a firm decision after an objective evaluation of recommendations from his staff and others directly concerned.

We occasionally encounter an operation that is achieving creditable results as a "one-man show." However, this requires exceptional capabilities on the part of the man who is administering it. Most men who have such capa-

Recent developments in drugs and medicines, changes in the size of manpower engaged in their production and compounding, changes in the nature of products, materials, and dosage forms, cost and price developments, and changes in the dollar volume of prescription pharmaceuticals are reviewed.

Drugs and Medicines

LUCY M. KRAMER

OVER the past few decades, new drugs and medicines have contributed importantly to progress in public health. "Miracle" drugs have lowered national death rates and sharply reduced acute communicable diseases.

Since the introduction of sulfa drugs in 1937, deaths from influenza-pneumonia have decreased 75 percent, from 114.9 per 100,000 in 1937 to 27.1 per 100,000 in 1955 (1). The principal diseases of childhood—scarlet fever, streptococcal sore throat, diphtheria, whooping cough, measles—which caused 10 deaths per 100,000 children in 1945, in the space of only 10 years dropped to 1 death per 100,000, a decrease of 90 percent (2). According to unpublished data of the National Office of Vital Statistics, the mortality from all infectious diseases dropped in 50 years from 676.2 per 100,000 in 1900 to 44.3 per 100,000 in 1956.

Drugs and medicines have transformed both the practice of medicine and the patients' use of health services. The drug industry responsible for the development, production, and distribution of these products has helped to support medical research in its own laboratories and in the medical schools, universities, and teaching hospitals of the country. The industry is presently participating in the extensive cancer chemotherapy studies of the Na-

tional Institutes of Health, Public Health Service. Drug firms and community pharmacists also have assisted in the health education programs of health departments and voluntary health agencies.

Pharmaceutical Manpower

About 2 million persons are employed in health occupations. About 111,000 of these are registered pharmacists (3). In addition to those directly employed in the provision of health services, nearly 200,000 are engaged in supplying goods and services essential to health occupations (4). According to the 1954 Census of Manufactures, these persons were engaged in affiliated industries such as the production of scientific and professional instruments and supplies (including medical, surgical, dental, and optical); biological, medicinal, chemical, and pharmaceutical preparations; ophthalmic goods; X-ray and therapeutic apparatus. Of these, the largest number—some 92,000—were engaged in the manufacture of drugs and medicines. In addition to skilled operatives, clerical, and other employees, the drug firms reported 380 physicians in their employ as of January 1957 as compared with 155 ten years before and 65 twenty years earlier. The total number of employees with graduate degrees in the medical and allied sciences was 3,000 as of January 1957 compared

associate executive director; Dr. James L. Troupin, assistant director assigned to the association's committee on professional education; Noble Swearingen, director of Washington, D. C., office; Robert Mytinger, director of western regional office, San Francisco; and Dr. Edward Wellin, who will study the relation between public health and the behavioral sciences.

Desalting Water

Coalinga (population 6,000), Calif., will be the first community in the United States to obtain its entire supply of drinking water through electronic desalting of brackish water.

An \$80,000 apparatus will produce 28,000 gallons of drinking water daily at a cost of about \$1 per 1,000 gallons after the unit is paid for.

Coalinga has been carrying drinking water by railroad from Armona, 45 miles away, at a cost of about \$7 per 1,000 gallons. The city's well water contains approximately 2,000 ppm of salt.

Voluntary Admissions

A new provision in New York State's mental hygiene law reduces from 60 days to 15 days the maximum time a voluntary patient may be detained in a State hospital at the discretion of the director. It also reduces from 15 days to 10 days the time a voluntary patient may be detained after he has given written notice of his intention to leave.

Operation Cleanup

Sanitary conditions in Laredo, Tex., have been improved as the result of a 4-stage vector control project. To reduce the large rat population and vast numbers of flies and mosquitoes at peak season, the city attacked the breeding and feeding grounds (refuse dumps, privies, ill-kept garbage cans, and open, flat trucks used for refuse removal) as well as the vectors directly.

In cooperation with the city of Laredo, the Texas State Department

of Health and the Public Health Service began the project in 1954 with surveys of unsavory spots, sewage facilities, and waste disposal practices. Ten covered trucks were purchased to carry refuse to the new controlled sanitary landfills. Galvanized garbage cans, placed on elevated racks, were bought by 10,000 families in 1 month.

Since most of the privies were near sewer lines, nine different plans were applied to help small homeowners without funds to install modern plumbing. The city also began extending its sewer lines.

Warfarin reduced the proportion of rat-infested premises from 75 to 5 percent, with a consequent disappearance of typhus fever. Sprays cut down flies and mosquitoes, with a consequent drop in the incidence of diarrheal diseases. Insecticides and rodenticides, however, are only used as a supplement to the main work of eliminating breeding potentials.

The project continues with plans to create parks and playgrounds over landfilled areas.

X-rays Discontinued

The Christmas Seal mobile X-ray unit of the Buffalo and Erie County Tuberculosis Association was officially discontinued in July 1958. When special circumstances warrant, services for select groups will be arranged by the association with the Erie County and New York State Health Departments' X-ray units.

Appointments

The American Public Health Association has announced five new appointments: Dr. Thomas Hood,

Indian Self-Help

Indians are helping themselves to health. Ute tribal council financed \$100,000 water system to serve 100 homes in Towaoc, Colo. Navajo tribal council budgeted \$206,750 for 1959 for equipment in health facilities, emergency care for students, prosthetic appliances, hearing aids, and glasses. Navajos also offer free layettes for babies born in hospitals or brought to hospitals for examination in their first month.

Immunization

A complete immunization program, reported as a "first" in the State, has been set up for all patients and employees in Pennsylvania's State institutions.

Patients and employees will be immunized against smallpox, diphtheria, tetanus, typhoid, influenza, poliomyelitis, and tuberculosis.

Sanitarians in the Butte County Health Department, Calif., have inspected the operational safety of X-ray units of 50 physicians, veterinarians, and dentists at their request.

A health education show last August, the first to be held in New York City's Coliseum, attracted 40,000 visitors.

Burning discarded automobiles and parts in the open air has been banned in New York City. It is estimated that 200,000 cars had been burned annually in the city by automobile wreckers. Incinerators now on the market will take over the job.

Figure 1. Trend in National Formulary basic drugs, 1916-55.

SOURCE: Reference 12a. Based on Journal of the American Pharmaceutical Association (Practical Pharmacy Edition) 16: 424-425, July 1955.

Pharmacopeias as shown in table 1 also reflect the tremendous increase in certain types of drugs during a 5-year period. The fifteenth U. S. P., released in August 1955, lists almost 250 new drugs that have been officially accepted for inclusion after stringent review (12a). The new U. S. P., scheduled for publication in 1960, will have an even larger number of new drugs.

Since 1948, more than 3,000 new prescription drug items have entered the market, each with an average life span of 2 to 5 years, and the forecast for new drugs looks even busier (13). In 1940, less than 100 new specialties were introduced (14). In 1957 alone there were 400 new pharmaceutical products put on the market, some of which were entirely new chemical entities; others, new combinations or new dosage forms of less recently new drugs (15, 16a). It has been said that a majority of the prescriptions written today could not have been filled 20 years ago since many of the drugs now used were unknown. Sulfa drugs were introduced in 1937; penicillin in 1940; streptomycin in 1946; antihistamines in 1947; cortisone, ACTH, and hydrocortisone in 1950

and 1951; chlortetracycline U. S. P. (Aureomycin), chloramphenicol U. S. P. (Chloromycetin), and oxytetracycline U. S. P. (Terramycin) in 1950; rauwolfia and certain types of psychopharmacologic agents (for example, meprobamate) in 1953.

In dollar value of total prescriptions filled, antibiotics today account for about 25 percent of total volume (16a). Antibiotics also represent about 25 percent of drug purchases in Public Health Service hospitals (17). (An economic study by the Federal Trade Commission of the entire antibiotic industry, covering prices in particular, but also including patents, manufacturing processes, and other aspects, was recently published, and should throw needed light on this extensively used drug category.)

About 7 cents of every dollar spent for drugs in Public Health Service hospitals in fiscal 1957 was for psychopharmacologic medications (tranquilizers) (17). The proportion is expected to go higher in 1958. Expenditures and use with respect to tranquilizers by the general population parallels Public Health Service experience.

The future of the drug industry is now based on constantly developing new products. A president of one of the leading drug firms has stated "the pharmaceutical industry lives in the shadow of its own obsolescence" (16b).

With the intensified current basic research

with 990 ten years before and 300 twenty years earlier (5).

The number engaged directly in health occupations or in affiliated industries is approximately double the 1.1 million estimate of 1929, the latest year of high-level employment in the pre-antibiotic era (6).

The number of pharmacists, however, has not grown correspondingly. Wholly comparable figures for the several decades are not available. Rorem and Fischelis reported for 1931 some 115,000 registered full-time pharmacists in the United States, and a total of about 130,000 individuals legally recognized to practice pharmacy either as fully registered pharmacists or as auxiliary assistants (after making a correction for the many duplicate registrations, that is, registrations issued to the same individual by several States) (7a). In 1955 some 158,775 registrations were held by pharmacists in good standing (many of them duplicates), of which 110,992 were held by pharmacists engaged in active practice in the various States (8a). By the end of 1956, the number of such registrations had increased to 162,459 (9a), but the number held by pharmacists engaged in active practice had decreased slightly to 110,688 (9b). It appears that the number of active pharmacists has not changed materially since 1931.

For the Nation as a whole, in 1955 there were 67 practicing pharmacists per 100,000 population, about half the physician-population ratio. About 89 percent of the pharmacists were engaged in retail pharmacies, 4 percent in hospital pharmacies, 6 percent in manufacturing or wholesale establishments or as representatives of the establishments, and 1 percent in teaching or government positions (8b). Today, about 10 percent of new graduates are going into hospital pharmacy work, and more than 5 percent of the total working pharmacist population is currently so employed (10a). Thirty-eight percent of the pharmacists employed in hospitals and 6 percent in the profession as a whole are women (10b).

The Census of Pharmacy reports that there were 52,779 retail pharmacies at the end of 1955 and 1,176 hospital pharmacies dispensing drugs and medicines. In addition 37,515 dealers other than pharmacists were licensed

in the various States to sell packaged drugs (8c). The number of retail pharmacies has declined absolutely since 1929 (from approximately 60,000 to about 53,000 in 1955), and in proportion to population (7b, 8c). In the 40 years prior to 1929, the population per drug store declined somewhat. In 1890 the population per drug store was 1,838 and in 1895 it was 1,745. By 1903 the ratio had increased to 2,030 persons per drug store, where it remained almost constant for more than 25 years. Since 1929 the population-drug store ratio has increased from 2,020 (7c) to 3,126 in 1955 (8c), that is, there are fewer drug stores for more people (with a trend toward larger prescription departments and less general drug store merchandising).

In contrast the drug manufacturing industry has expanded markedly since 1929 in number of employees. Almost four times as many employees were engaged in the manufacture of drugs and medicines in 1954 (11) as were employed in 1929 (7d).

Products and Materials

The drug industry since the advent of sulfa drugs in 1937 has been characterized by rapid change. The rate of change has been so accelerated that progress in the last 30 years may well have exceeded that of several centuries before.

A recent analysis of the basic drugs listed in the National Formulary between 1916 and 1955 reflects the sharp change in the relative importance of basic materials in the drug industry (12a).

In 1916, almost 80 percent of the basic drugs were of botanical origin, 10 percent of organic chemical origin, and 10 percent of inorganic chemical origin. In 1955, the use of botanicals had dropped to 30 percent, organic chemicals had risen to 50 percent, and inorganic chemicals to 20 percent (fig. 1).

Botanical sources have been replaced by organic chemical sources that are more easily available, more concentrated, more easily controlled in their manufacture, and more specifically effective.

Changes in the principal categories of drugs listed in the 1950 and 1955 United States

and chemical industry, he is required to have scientific knowledge and the ability to impart and rise it effectively in selling prescription drug products (22). He often is a pharmacist, sometimes a medical student or graduate, always a well-informed individual. His duties are to visit physicians, dentists, veterinarians, wholesale and retail druggists, hospitals, clinics, and dispensaries, exporters, and all other possible purchasers of his company's pharmaceutical preparations. He is the means by which the results of research and development become directly known and used. Although exact figures on the number of such "detailmen" currently in the labor force is not available, the number of registered pharmacists alone representing manufacturers and wholesalers of drugs increased from 2,415 in 1955 to 2,739 in 1956 (8*b*, 9*c*).

Dosage and Dosage Forms

The Bureau of Labor Statistics has for many years included in its medical care component of the Consumers Price Index a breakdown of drug items used in selected prescriptions with the content and dosage form carefully specified. A typical prescription unit for pricing is specified as a "capsule" prepared by a compounding pharmacist.

The pharmacist-compounded capsule era, together with the era of powders and potions in medication is ending, however. By 1955, tablets produced by a pharmaceutical house in wholesale quantities represented the typical dosage form; parenterals and liquids held second place. Together they accounted for about 75 percent of the new drug dosage (12*a*).

Analysis of the 20 largest volume prescription items currently being dispensed in a Public Health Service outpatient pharmacy shows that 13 of the 20, or 65 percent, are dispensed in tablet form.

Aspirin, which leads all other drugs in volume of output—161½ million pounds in 1956, an increase of 159 percent in the last 16 years—is one of the tablets that has become standardized in content, shape, and size.

Not only has the tablet become the typical dosage form, but the efficacy per tablet is constantly being increased. A penicillin tablet

with a built-in delayed action mechanism has been developed which would require only one tablet per day for 24-hour medication. Other tablets (and some capsules and granules) have been developed and marketed recently which contain in one medication several different drugs in various doses that are released into the system at various times.

The traditional injection of insulin may someday be replaced by a tablet, and has already been in certain cases. A sulfa drug, tolbutamide (Orinase), has been used in about 250,000 cases of diabetes, most of them mild, and on patients over 20 years old. Its efficacy depends on prodding the pancreas into doing its own work. Oral medications are less traumatic than hypodermic injections, are considerably less dangerous and troublesome, and require no sterilization (23).

The controllable techniques involved in the production and distribution of tablets, the standardization of size, shape, and color, the stability of the product, the general public acceptance of tablets as a form of medication, and the ease with which dosages can be taken, all contribute to the increasing manufacture and use of tablets as dosage forms.

Cost and Price Trends

Medications have become more complex, more effective, and more expensive. Writing about 1929, Rorem and Fischelis stated: "The amounts spent by individuals or families for drugs and medicines during a given period do not show a wide variation, and seldom, if ever, amount to totals which are catastrophic in their effects" (7*h*). Individual prescriptions, however, are now far more costly and families may incur sizable drug expenses especially in cases of prolonged or chronic illness. Children for whom maintenance dosages of antihistamines and other drugs are prescribed, for example, may have long-term drug bills of \$15 or more a month, without any allowance for cost of additional dosages required during acute stages of illness. Older people with cardiac, hypertensive, or arthritic conditions may have maintenance medications prescribed for them which total \$25 or more a month. In the 1952-53 study of family medical expense it

in mental illness, coronary diseases, cancer, and chronic problems of old age, a poll of leading drug company executives indicates that they expect drugs affecting these types of illnesses to be important in the next 5 or 10 years (16b).

Highlighting the anticipated drug needs of the future are the following (18):

1. Drugs which will permit therapeutic approaches to a variety of mental illnesses and personality problems.
2. New chemical and antibiotic treatments to arrest certain forms of cancer.
3. New treatments for the prevention and cure of hypertension and other circulatory ills.
4. New developments to control degenerative diseases.
5. New discoveries for the better management of nutrition.
6. New products to subjugate a number of the still resistant viral diseases.

Pharmacist and New Products

One consequence of the newer drugs and the growth of the medical materials industry has been a change in the function of the pharmacist. Writing in 1929, Fischelis emphasized that the "development of machine production of pharmaceuticals has left its mark on the retail pharmacies in that it has reduced the function of the apothecary in many cases to that of dispensing prepared medicines" (19). The products developed in the subsequent years have accelerated the trend observed by Dr. Fischelis 30 years ago.

The pharmacist is no longer primarily the compounder of powders, ointments, and potions, but the dispenser of prefabricated medicines on prescription. More than 80 percent of all prescriptions sold at present are dispensed rather than compounded (13).

Another consequence has been a sharp increase in prescription practice of the drug store. Prescription volume increased from an average of less than 10 percent of total drug store sales some 30 years ago (7e, 20) to about 30 percent at the present time (21a, b). The average prescription price has increased during that period almost as rapidly as the volume (table 2). Total drug sales, including prescription accessories and packaged medicines,

Table 2. Ratio of prescription volume to total drug store sales and average prescription prices for selected years, 1929, 1931, 1941, 1946-56

Year ¹	Ratio of prescription volume to total sales (percent)	Average prescription price
1929-----	8.5	\$0.85
1931-----	8.1	.92
1941-----	13.2	.93
1946-----	15.8	1.33
1947-----	16.6	1.41
1948-----	18.8	1.51
1949-----	19.0	1.60
1950-----	20.4	1.77
1951-----	21.8	1.90
1952-----	23.7	2.08
1953-----	24.2	2.19
1954-----	24.9	2.27
1955-----	27.3	2.46
1956-----	29.5	2.62

¹ SOURCE: For 1929, reference 7e; for 1931, reference 20; and for 1941, reference 21a,b.

account for about 50 percent of drug store sales (16c).

Total drug store sales in 1929 amounted to \$1,650 million (7b); in 1956 these sales had risen 358 percent to \$5,912 million (16a). During the same period prescription volume grew from about \$140 million (7e) to \$1,466 million (16a), an increase of more than 1,000 percent, almost three times as fast as total drug store sales. Rorem and Fischelis have observed that the index of drug sales volume does not parallel disease incidence, but tends to reflect the level of expendable consumer income (7f).

A third consequence is the increase in the share of drug sales to hospitals. Of an estimated expenditure of \$190 million in 1929 for prescription drugs, hospitals and dispensaries purchased \$25 million, or less than 13 percent; drug stores bought \$140 million, or 74 percent; and physicians accounted for the remaining \$25 million (7g). A recent survey shows that about 24 percent of prescription drugs now goes to hospitals, 56 percent to drug stores, and 20 percent to physicians (12b).

A fourth consequence has been the rise in importance to doctor, pharmacist, and hospital of the "detailman." As a professional service representative in the pharmaceutical

Figure 2. Personal expenditures for drugs and sundries and all medical care for selected years, 1929, 1939, 1946, 1956.

(from 59.3 to 116.2); the medical care index (all items) rose 85 percent (from 71.6 to 132.6); and prescriptions, drugs, and medical supplies rose only 37 percent (from 82.8 to 113.7). Prescriptions, drugs, and supplies make up about 17 percent of all medical care, and medical care about 5.4 percent of all items in the Consumer Price Index.

During the first decade, from 1936 to 1946, the medical care index rose relatively slowly, only one-third above 1936. The rest of its increase, two-thirds, occurred in the second decade, from 1946 to 1956. In the overall 20-year rise, medical care ranked fourth after food, personal care, and apparel.

In the 10-year period from 1946 to 1956, the total medical care index increased to 132.6 as compared with 116.2 for all items (1947-49=100). Within the medical care category are included doctors', surgeons', and dentists' fees, optometric examinations and eyeglasses, hospital room rates, group hospitalization, prescriptions and drugs. Hospital room rates

showed the largest increase, rising to 173.3. Prescriptions and drugs, combined, increased to 113.7. Prescriptions, alone, increased to 121.0, largely as a result of the new drugs. Figure 3 shows the relative increases in total medical care index in the last 10 years, and in prescriptions and drugs particularly. The index of aspirin prices was 125 in 1929 (1947-49=100), fell steadily to 97.6 in 1941, rose to about 100 in 1948, and has remained at more or less the same level since.

The second type of price series represents average prescription prices. Whereas the Bureau of Labor Statistics drug price series measures changes in price for a specified "basket of drug items" selected as of a given period, the average prescription price series reflects changes in the drug item purchased.

The average prescription prices increased from about \$0.85 in 1929 to \$2.62 in 1956, a more than threefold increase (table 2). Average prescription prices in 1956 varied from \$2.49 to \$2.79, according to different surveys. A recent figure for 1957 gives \$2.93 as the average prescription price, the highest on record (16a).

The average price per unit of many of the newer drug types is more than \$3 per prescription. For about 8 of the 26 drug classifications used by the *American Druggist* in its annual prescription survey—classifications accounting for about 54 percent of prescriptions sales in 1956—the average price per prescription was over \$3. In 1957, the figures are even

was found that 2 percent of the families incurred charges for medicines in excess of \$195 per year (24).

Average family or per capita expenditures for drugs, however, have increased somewhat less than disposable income, that is, family income after taxes. In 1956, \$1,885 million was spent by the Nation's families for drugs, medical supplies, and sundries, exclusive of drugs and dressings used in hospitals or dispensed by physicians. This represents an annual outlay of 0.66 percent of disposable income, or \$35.70 per family and \$11.41 per person. In 1929 personal spending for drugs, medical supplies, and sundries amounted to \$604 million, or 0.73 percent, of disposable income, an expenditure of \$16.73 per family and \$4.96 per person (table 3). During that time disposable personal income increased from \$83.1 billion to \$287.2 billion, an increase of 346 percent; personal spending for drugs, medical supplies, and sundries increased only 312 percent (25a, b, c).

Personal expenditures for drugs, medical supplies, and sundries have increased since 1929 less than medical care generally and less than many items within the medical care component. In part this may reflect higher real incomes of the Nation's families, improved health education, increased use of physician services, and the relative growth of prescribed as compared with nonprescribed drugs. In

part this may reflect the expanded use of hospital care and the relative increase in costs of various services included in hospital care. As a consequence (fig. 2), drugs, medical supplies, and sundries as a personal expenditure represented a smaller part of the personal medical care dollar in 1956 than even 10 years earlier in 1946, or than in 1939 and 1929 (25a, b, c).

Drug costs as a part of hospital costs, however, have risen significantly more than other components of the hospital dollar. The Commission on Financing Hospital Care found that drugs as a percent of hospital costs between 1942 and 1952 had increased more than 300 percent (table 4), a greater increase than any other of the services analyzed (26).

Personal or hospital drug expenditures reflect changes in volume of use of medications, types of drugs used, and price per unit.

There are also data which show only the changes in price per unit, without reflecting volume of prescriptions. Two basic types of price series are available as measures of retail price changes.

The first type is the often-quoted price series compiled by the Bureau of Labor Statistics. According to the Bureau of Labor Statistics Consumer Price Index, a measure of change in the price of specified items customarily purchased by urban wage-earner and clerical-worker families (27), the price index of all items rose 96 percent between 1936 and 1956

Table 3. Disposable personal income, personal spending for medical care, and for drugs and sundries (per capita and per family) for selected years, 1929, 1931, 1939, 1941, 1946, 1951-56

Year	Disposable personal income (millions) ¹	Personal medical care expenditures (millions)	Personal expenditures for drugs and sundries				
			Total (millions)	Percent disposable personal income	Percent medical care	Per capita	Per family
1929	\$83,120	² \$2,937	² \$604	0.73	20.6	\$4.96	\$16.73
1931	63,840	² 2,549	² 517	.81	20.3	4.17	14.05

SOURCES: ¹ Reference 25a. ² Reference 25b. ³ Reference 25c.

ment of hearing. Today \$15 worth of antibiotics clears up most cases without surgery (29c). Syphilis was an important cause of expensive and protracted illness two decades ago. Today, syphilis is often "cured" or at least brought under control with one shot of long-acting penicillin (14). In the United States, penicillin has completely supplanted older forms of therapy such as arsenic and bismuth (30). New drugs, including isoniazid, have helped to reduce deaths from tuberculosis. Between 1946 and 1955 the tuberculosis death rate dropped from 34.9 per 100,000 to 9.1 per 100,000, a decrease of almost 75 percent (2). Many patients are now cured at home in a small fraction of the time, and the cost, it took when prolonged rest in a sanatorium was the major technique.

Volume of Prescription Pharmaceuticals

A recent guide to the sales and status of the drug market warns the reader, "Before using this book, we suggest that you rid yourself of all old conceptions of the magnitude of the volume of manufacturers' sales of ethically promoted pharmaceuticals for human use. Otherwise today's figures will seem fantastic. Times have changed. We sometimes look back with nostalgia to 1929 when the manufacturers' sales amounted to about \$250 million. Think now of sales in manufacturers' dollars of nearly \$6 for each and every one of 165 million persons in the United States!" (12c).

From 1929 to 1955, then, the sales volume of manufactured prescription pharmaceuticals almost quadrupled, from \$250 million to \$990 million. Current trends show sales to be considerably higher.

In a recent speech before the 61st Annual Conference of Food and Drug Officials of the United States, an official of one of the major drug laboratories said that 10 leading drug houses alone, in their 1956 annual reports, showed sales that ranged from \$100 million to \$200 million (31).

One drug company reports sales in 1957 of \$207 million as compared with its 1956 sales of \$178 million (32). Its 1958 sales for the first quarter were \$54 million as compared with \$51 million in 1957; its 1958 earnings for the same

period were \$6½ million, 19 percent above 1957 and a record high (33).

The manufacture of prescription pharmaceuticals is now well over a \$2 billion industry. The increased volume of wholesale drug sales is of course reflected in the increased retail prescription volume.

An industry publication, in its Silver Anniversary issue, stated: "Drug store sales volume in 1956 was the highest ever recorded" (21c). In an 11-year period the number of prescription sales increased by 50 percent and the income from prescriptions tripled, largely because of increase in average prescription prices, but to some extent from an increase in the number of prescriptions dispensed (21d). "The 11-year rise in average prescription prices is due to the tremendous increase in the widespread use of new therapeutic agents, virtually all of which are costly to dispense." (21b).

Summary

The nature of the drug industry has changed in the last 30 years. With it has changed the manpower in the industry and the pharmacist's role—from a compounder to a dispenser of drugs. The increased number of drugs and their complexities have intensified his services as drug therapy consultant to physicians and dentists. The basic sources and compounding of pharmaceuticals have changed in character, and have increasingly become the object of intensive research by both private and public organizations in the effort to develop specific drugs for specific illnesses. The dosage and dosage forms have become more concentrated and standardized, generally in tablet form. Drugs represent a decreasing proportion of the medical care dollar and of disposable income. The price of drugs generally has been high for new items, falling with volume use and production, or obsolescence. Average price per prescription has doubled since 1946 and more than tripled since 1929. The length of some illnesses has been shortened by the development of specific therapies, and the cost has been cut even though drugs are more expensive. The volume of manufactured prescription pharmaceuticals increased from \$250 million in 1929 to more than \$2 billion in 1956, a tenfold increase in

Figure 3. Consumer price indexes for medical care items, annual averages.

more revealing. Table 5 shows that 8 of the 26 classifications accounted for 60 percent of the dollar value of prescriptions; all averaged more than \$3 per prescription, and two more than \$4 (16a, d).

Prices of new drugs follow a characteristic pattern of decline after initial introduction, and when volume use and production take place. Penicillin in 1943 sold for \$20 per 100,000 units in injectable form. In 1956, it sold for \$0.20 per 100,000 units in tablet form, a drop of 99 percent (28a, 29a). Since its introduction in 1950, cortisone has dropped 90 percent in price (15). Within 2 years of its introduction cortisone fell from \$200 per gram when made from animal bile to \$50 when made from yams and other plants (28a). Streptomycin dropped 40 percent in less than a year (13). Insulin now costs about 6 percent of what it did 30 years ago, shortly after it was introduced (28b).

The downward movement in prices of new drugs is a brake on the prescription price index. However, this type of price index is also influenced by the distribution of prescriptions among different kinds of drugs, as well as by

the rapid obsolescence of drug items and their continuous replacement by newer, more effective, and, at original issue, more expensive drugs.

Drug and Illness Costs

The cost of medicines may also be viewed as a part of the cost of illness. As indicated earlier the percent of the personal medical dollar going to drugs, medical supplies, and sundries has declined. In terms of specific illnesses drug costs have risen sharply but have been instrumental in reducing the total medical outlays and in shortening hospital stays and time loss from productive activity.

According to one source, 20 years ago a case of lobar pneumonia meant 5 weeks in a hospital, long convalescence, and \$300 to \$400 for doctors, nurses, medicine, oxygen, and hospital care. Today it means 2 weeks of illness, generally at home, back to work immediately thereafter, and \$15 to \$30 for drugs (29b).

Thirty years ago the treatment of mastoiditis cost at least \$1,000, required surgery, and involved the possibility of permanent impair-

Table 5. Comparison of selected prescription types by percent of total dollar value of all prescriptions sold, and average price, for 1956 and 1957

Prescription type	Percent of total dollar value		Average price	
	1956	1957	1956	1957
Anti-infectives.....	24.1	25.4	\$3.68	\$4.03

Interstate Shipment of Milk

Ban on out-of-state milk, unless produced and handled under conditions no less adequate in protection of public health than milk produced in State upheld. *James v. Todd*, 103 So. 2d 19 (Alabama, Aug. 22, 1957).

A declaratory judgment of the Supreme Court of Alabama has upheld the validity of an Alabama statute (Act No. 570, 1955 Acts) prohibiting the shipment of milk into Alabama from another State "unless such milk is produced and handled under sanitary conditions no less adequate in protection of public health than milk produced in the State of Alabama," and authorizing the State Commissioner of Agriculture and Industries to inspect the conditions under which out-of-state milk was produced and to issue and revoke permits for transportation of such milk into Alabama.

After citing *Milk Control Board of Pennsylvania v. Eisenberg Farm Products*, 306 U. S. 346, 59 S. Ct. 528 as evidencing recognition by the Supreme Court of the United States that the milk business is essentially local and, therefore, subject to the police power of the State, the Alabama court stated:

"Under its police power, the State of Alabama is authorized to enact laws designed to protect the health of its citizens and more particularly where milk is concerned because of its nutritional importance to human beings and because of its susceptibility to contamination. . . . The Legislature may even grant to a municipality the power to provide health regulations."

The mere fact that the statute was applicable only to out-of-state milk did not, the court held, constitute an unreasonable discrimina-

tion or a burden on interstate commerce. The validity of the statute was, however, held to depend on whether it was a reasonable system established as a safeguard of the public health or a system calculated to prevent the importation of out-of-state milk in competition with local supplies. The court distinguished *Dean Milk Co. v. City of Madison*, 340 U. S. 349 (where the appellant was denied a license to sell milk in the city because its plant was more than 5 miles away), and other related cases, on the ground that those cases dealt with the administration or enforcement of statutes which in operation "made it practically impossible to import . . . goods into the State."

While the court conceded that in the administration of the Alabama Act there was a possibility of abuses such as would raise a question of its constitutionality, it concluded that the statute, on its face, was reasonably related to the protection of the public health and was not intended to prevent the importation of out-of-state milk in order to eliminate competition with local supplies.

The court warned, however, that enforcement of the statute under a construction (supportable under the literal language of the act) which would limit permits to shippers of milk, and hence exclude milk from out-of-state producers who were not also shippers, would be unconstitutional.

less than 30 years. The volume of retail prescriptions has increased during that period, from \$140 million to \$1,466 million.

Occupational Health at a University

GEORGE S. MICHAELSEN, M.S.

OCCUPATIONAL HEALTH programs of official agencies have rather consistently overlooked the college as an area where preventive occupational health work could be profitably carried on.

There may be several reasons for this. Perhaps one is that these agencies have been so industry-oriented that they have overlooked the academic staff, other employees, and students of the larger colleges and universities as industrial or occupational groups with which to work. Another reason could well be the prevailing misconception that chemists, physicists, bacteriologists, engineers, and other similar professionally trained people know the potential health hazards of the materials and processes they use. The assumption follows that they also take the necessary precautions to protect themselves.

I can assure you, after working for several years with such professionally skilled personnel, this is definitely not so. Some well-informed persons are outstanding in the real concern they show for their own health and safety as well as that of their colleagues and assistants. But most have not sought information about possible health hazards in their work. I must add, however, that I have found academicians without exception to be a most receptive and interested group ready to accept the

facts and willing to cooperate in instituting corrective measures.

Even though our sights are gradually lifting from the strictly industrial to the broader concept of occupational health, the colleges and universities are still being overlooked. Generally, the administrative heads of colleges and universities fail to recognize that the campuses have occupational health hazards and often dangerous situations.

Sponsored research, both basic and applied, is now a multimillion dollar business for colleges and universities, vastly increasing research activities and staffs. At present many scientists are employed solely for research. They have no teaching responsibilities even though they are members of the academic staff. Their laboratories are no different from those in the research department of a large industry.

Campus Health Hazards

A large university campus has all the health hazards of industry and frequently some which have not yet reached the industrial stage. The latter hazards are the most troublesome to the occupational health engineer on the campus. Many times he can make only a wild guess as to the toxic properties of the materials being used, and in such cases he is inclined to be very conservative. At the same time he must not be so stringent in his control measures that it becomes virtually impossible to carry out the research project. To date, such problems at the University of Minnesota predominantly have concerned new agricultural chemicals and the resistance of various materials to chemical action at high temperatures and pressures.

Mr. Michaelsen is associate professor, School of Public Health, and industrial health engineer, university health service, at the University of Minnesota in Minneapolis. This article is based upon a paper presented at the 20th annual meeting of the American Conference of Governmental Industrial Hygienists at Atlantic City, N. J., April 21, 1958.

Public Health Dentistry

The School of Hygiene and Public Health at the University of São Paulo is now training dentists to administer dental public health programs in Latin America. The course of study, leading to a degree equivalent to master of public health, is the first such course in Brazil.

Sixteen dentists, half of them studying under World Health Organization fellowships, enrolled in the course in February 1958. They come from Argentina, Brazil, Colombia, Costa Rica, El Salvador, Paraguay, Peru, and the Dominican Republic.

They study general public health subjects with physicians, veterinarians, and engineers. Separate classes on specific dental subjects include refresher courses in dental techniques, current information and methods in caries prevention, and technical guidance during field work.

Several agencies are cooperating with the university in this course. WHO provides advisory services, fellowships, and teaching materials; the Kellogg Foundation gives financial aid, equipment, and supplies; and Serviço Especial de Saúde Pública participates in the students' field training.

—ALFREDO REIS VIEGAS, D.D.S., M.P.H., *assistant professor, School of Hygiene and Public Health, University of São Paulo, Brazil.*

Typhus Among the Araucanians

In Cautín Province, Chile, where the National Health Service has battled classic louseborne typhus fever for several years, are some 150,000 Araucanian Indians, the people celebrated in Ercilla's epic poem, "La Araucana."

The Araucanians live primitively in *rucas*, or huts, much as they did when they successfully withstood for hundreds of years both Inca and Spanish conquest. Their huts are scattered singly and in three's and four's over a wide area, and they travel long

distances on foot, horseback, or by oxcart. But their custom of attending funerals in extraordinarily large numbers has helped to spread typhus, which they carry back to their home areas after these gatherings.

We visited the central Chilean province, which has an endemic focus of typhus, to get first-hand information after the National Health Service asked for help in eradicating the disease. The area where most work is needed is impassable to motor vehicles 9 months of the year, and only jeeps can be used the other 3 months. Nevertheless, we hope to start a combined disinfection and typhus vaccination campaign the latter part of 1958.

—G. HOWARD GOWEN, M.D., *chief, Health and Sanitation Division, U. S. Operations Mission, Chile.*

The Mountain People

The way of life of the mountain people in the Philippines makes it difficult for malaria eradication teams to protect them from the disease. Dissident and evasive with lowlanders, the mountaineers are hard to reach. Distribution of a drug-salt mixture is planned.

The mountain people withdraw from the settlements and follow their own customs in remote, high, forested areas. Some grow mountain rice and sweet potatoes on cleared plots which they abandon after a year or two. Others simply gather the food nature provides. Houses may be nonexistent, or tree dwellings, or roofed platforms, or permanent structures.

Practically all such groups have been found to be malarial to some degree and thus are reservoirs of infection. Intermittently, the mountain people come to the settlements to trade for salt or other articles or to work as itinerant farm laborers. This influx of chronically infected people causes continual transmission.

Malaria among the mountaineers has helped to disprove the assumption that malaria cannot be transmitted at heights above 2,000 feet, because of the habits of the principal vector, *Anopheles minimus flavirostris*. Several other anophelines, whose habitats extend to 3,300 or even 5,500 feet, have been incriminated by anopheline dissection.

—JOHN W. McDOWELL, *malaria control adviser, U. S. Operations Mission, Republic of the Philippines.*

The bulk of the instruction is carried out on the three campuses. There are also 5 agricultural experimental stations and schools in outlying parts of the State; an 8,000-acre center for all types of research 25 miles south of the Minneapolis campus; a 2,000-acre wildlife preserve 25 miles north of the St. Paul campus for research on wildlife, forests, lakes, and streams; and a number of smaller stations and research facilities.

Three factors of the division's administrative arrangement we feel are highly desirable. First, the occupational health engineer is a part of a professional team. Close association with the radiological health and safety personnel is particularly helpful to him because occupational health problems frequently involve these fields. Occupational health and safety are very closely allied; in fact, it is often difficult to distinguish between them. Having specialists in both these fields on the same team rather than in different departments, where overlapping activities and contradictory recommendations might occur, is especially advantageous.

For example, the safety engineer was asked to consider the safety hazards of using solvents in a cryostat, a refrigerated, box-like apparatus employed to carry out laboratory procedures at extremely low temperatures. The operator uses insulated gloves mounted in the wall of the apparatus. Neither the motor-driven fan nor the electric lights inside it are explosion proof. From a safety standpoint, it would be hazardous to use solvents in this cabinet unless the temperature is maintained at all times below the flashpoint of the solvent. From an occupational health standpoint, the cryostat is a good device since the hazardous operation is fully enclosed.

The safety engineer is inclined to recommend that this work be done in a large walk-in freezer where it would be virtually impossible to create an explosive mixture. The occupational health engineer is inclined to veto this recommendation because of the dangers of inhaling solvents in a confined, unventilated space.

In this case, the conflicting interests were worked out by agreeing not to use solvents with combustible vapors in cryostats and by providing adequate ventilation in the walk-in freezers. If these two engineers had been in

different departments, such a compromise might have been made only after some misunderstanding and delay. In our case the conflict was resolved in minutes.

A second strong feature of the administrative plan is the academic appointments with teaching responsibilities of our staff members. Teaching occupational health forces us to be aware of all new developments, and working in an operating program provides us with a wealth of illustrations, examples, and demonstrations to use in the classroom.

The third feature is the division's close association with the medical staff of the health service which serves the staff and students. The medical staff members are alert to possible environmental factors of illnesses that come to their attention. For example, a student with severe headaches came to a staff physician. After detailed questioning, the physician was satisfied that the headaches were associated with the home environment. The occupational health engineer found 400 ppm carbon monoxide in the flue gases being discharged into the student's apartment by a gas refrigerator.

Several mercury and solvent hazard studies have been initiated at the request of physicians who have suspected such poisoning in students and laboratory workers seeking medical attention. The results of a survey of occupational health hazards on the campus have enabled the industrial health engineer and the physicians to advise the university's civil service department on the proper placement of a maintenance worker who suffers from certain specific allergies. Such requests for assistance and referral of problems would not be as frequent if the occupational health engineer and the physician were not in the same department.

A university occupational health program has all the usual elements of prevention, including preplacement and periodic physical examinations, evaluations of possible occupational health hazards, and recommendations for the corrections needed.

Survey of Hazards

One of its most profitable phases is a room-by-room survey of the entire campus for occupational health hazards. The broad activ-

Some idea of the variety and types of occupational health hazards on a college or university campus is indicated by this partial list of those that have occurred at the University of Minnesota in recent years:

- The sergeant in charge of the armory rifle range became ill with lead poisoning. Air sampling revealed atmospheric lead concentrations many times the maximum allowable concentration although only a portion of the range was used. Installation of an extensive ventilating system corrected this hazard.

- Scientists working on particle-size measurement were being overexposed to benzol in a filter cleaning operation. The use of local exhaust ventilation eliminated this hazard.

- Lead and solvent hazards have been studied in the print shop.

- The dangers of welding fumes have been eliminated from the maintenance shops.

- The carbon monoxide content of the air in the university's underground garages has been measured during periods of heavy usage.

- Excessive noise in wind tunnel, in jet engine testing, and in jet fuel combustion research has been evaluated.

- The mercury hazard has been studied in scores of laboratories.

- The misuse of carbon tetrachloride is campuswide and is being studied.

- Potential dangers in handling organic, phosphate-type insecticides in laboratory, greenhouse, and field have been studied.

In most of these problems only a few persons were exposed, which may be somewhat different from the industrial situation. Seldom are exposures to students great enough to cause actual poisoning or impairment of health, but control measures are instituted to alert students to potential hazards and to teach them what control measures are necessary in industry.

Although several institutions have teaching programs in occupational health, so far as I know, only the University of California, the Massachusetts Institute of Technology, and the University of Minnesota have operating functions in this field. Each of these three has a slightly different administrative pattern, undoubtedly dictated by the local situation. Colleges teaching occupational health may give

some service within their institutions when called upon, but in general they have no specific responsibility for the control of occupational disease hazards on their campuses.

University Health Service

The University of Minnesota is an autonomous branch of the State government, and all matters of health on its various campuses are a responsibility of the university health service. The Minnesota State Board of Health has therefore officially designated the university health service as a local health department; it is an independent service administratively under the academic vice-president.

The service's division of environmental health and safety was created to cope with the health aspects of water supply, waste disposal, food handling, student housing, swimming pools, radiological health, safety, and occupational hazards. On the staff of the division full time are 1 public health engineer, 1 occupational health engineer, 1 safety engineer, 3 health physicists, and 2 sanitarians, and part time, 2 engineers and a sanitarian. The full-time staff members also have academic appointments in the School of Public Health. This staff may seem large, but considering the size and geographic spread of the institution, it may be too small.

For a program with a wide scope of activities, it is highly desirable to have one or more physicians either on the occupational health staff or closely associated with it. At the University of Minnesota one of the health service physicians is assigned to give special attention to occupational diseases and to medical problems associated with exposure to ionizing radiation.

The University of Minnesota has the second largest enrollment of full-time students in the country, exceeded only by the University of California. In the fall of 1957 about 35,000 students were enrolled on the Minneapolis, St. Paul, and Duluth campuses and an estimated 90,000 a year in all forms of instruction—day, night, and extension classes and correspondence courses. To serve the student body the university employs about 10,000 people, 3,500 of these full-time academic staff members.

Progress in Reporting Mental Hospital Statistics

*Eighth Annual Conference of
Mental Hospital Statisticians
Sacramento, Calif., May 7-9, 1958*

A CAREFUL REVIEW and revision of definitions of terms describing the movement of mental hospital patients, refinement of cohort studies of admissions to mental hospitals, and a study of the socioeconomic characteristics of admissions to facilities for the mentally ill in relation to corresponding characteristics of the general population were major topics discussed at the Eighth Annual Conference of Mental Hospital Statisticians.

The conference, held in Sacramento, Calif., May 7-9, 1958, was sponsored by the National Institute of Mental Health, National Institutes of Health, Public Health Service. In attendance were delegates from 19 of the 20 States which are members of the Model Reporting Area for Mental Hospital Statistics (see box insert).

Observers from Massachusetts, Oregon, South Carolina, and Tennessee, and from the Veterans Administration were also present. Other guests represented Great Britain's General Register Office, Canada's Bureau of Statistics, the American Association on Mental Deficiency, the Joint Information Service of the American Psychiatric Association and the National Association for Mental Health, the Mental Health Project of the Western Interstate

Commission for Higher Education, and the Public Health Service office of Region IX.

Revision of Definitions

Uniform definitions of basic terms describing the movement of mental hospital populations have been in use by the members of the Model Reporting Area since 1952. While the use of these definitions has resulted in a greater degree of interstate comparability of data based on them, statisticians have found that these definitions lead to inconsistencies both within and between States. Consequently, a committee on definitions, appointed at the Seventh Annual Conference, recommended several changes, the most notable of which pertained to the definitions of first admission and transfer.

Until now, a first admission was defined as a patient who had not previously been admitted to a public or nonpublic hospital authorized or recognized for the treatment of mental disorders. Public hospitals include those operated by a State, city, county, or Federal agency. Nonpublic hospitals include those authorized or recognized for the treatment of mental disorders by a State mental hospital authority. The committee recommended that since there is considerable variation in the criteria used by these authorities in determining authorized or recognized hospitals it would be more appropriate to classify admissions by their type of previous hospitalization for mental disorders. The following classification of admissions to public mental hospitals was proposed by the committee and accepted by the conference:

This report was prepared by the Hospital Studies Section, Biometrics Branch, National Institute of Mental Health, Public Health Service, Bethesda, Md. For a short account of the establishment and objectives of the Model Reporting Area referred to in this report, see Public Health Reports, October 1956, p. 1033.

ities of the division of environmental health and safety mean we survey much more than the usual hazards. We include the following areas:

Fire and accident prevention. Adequate provision of gas masks, protective clothing, fire blankets, safety showers, illumination, first aid kits, and fire extinguishers.

General sanitation. Availability of eating accommodations and building incinerators, insect and rodent control, plumbing defects, and refuse disposal.

Animal care. Types of animals used, source of supply, isolation procedures, evidence of ectoparasites, cage cleaning methods, type of bedding, and disposal of solid wastes and dead animals.

Radiation hazards. X-ray machines, sealed or unsealed radionuclides, and other sources of ionizing radiation.

Building safety. Adequate exits, handrails, and stairways; guarding of machinery; grounding of electrical equipment; and the handling, storage, and disposal of flammable solvents.

The survey provides an unusual opportunity for the occupational health engineer to get acquainted with the institution and for the various branches of the university to become familiar with this health service function.

The occupational health engineer also reviews all plans for new buildings and major remodeling of older buildings at the university. At present, 48 such projects are in various stages of planning and building. These pro-

vide him with an unusual opportunity to recommend the proper ventilation to protect the health and welfare of the occupants, to review the need for process or special ventilation, hoods, safety showers, and fire extinguishers, and to check for adequate means of egress. The occupational health engineer also serves as consultant to the space allocations committee of the university, advising on health and safety considerations in the assignment of building space for various shops and research projects.

If it is to serve to its fullest capacity, a university occupational health program must be concerned with problems beyond those considered strictly health matters such as fire prevention and disposal of solid and liquid wastes which are combustible or toxic or both. The occupational health staff does not necessarily have to operate such programs, but should have an intimate working relationship with the persons responsible.

In other institutions where environmental health is not interpreted as broadly as at the University of Minnesota, to establish close-working relationships between the occupational health personnel and those responsible for other environmental problems would be highly advantageous. I urge those of you in the occupational health programs of government agencies to visit the colleges and universities in your area and offer to survey their facilities for occupational health hazards. You will find that you can assist them with a number of problems and you may find that they can help you with some of yours.

of released patients to determine the probability of their return to the hospital within specified periods of time following release. The conference members agreed that each State should submit a protocol of cohort studies which it is conducting or plans to conduct. A committee will then review these protocols and prepare a study design, conforming to the four criteria above, which could be carried out by as many of the States as possible. Such a protocol would be presented for consideration at the next annual conference.

Socioeconomic Studies

The possibility was discussed of conducting studies which would relate the socioeconomic characteristics of patients admitted to psychiatric facilities to those of the general population, as revealed by the 1960 population census. The primary objective would be to determine the extent to which various socioeconomic groups use the different psychiatric treatment facilities within a State.

It was hoped that some States would study the socioeconomic characteristics of those admitted to all types of psychiatric facilities and that other States might at least carry out more limited studies on patients admitted to only specific facilities, such as public mental hospitals.

One important aspect of the proposed socioeconomic study is the acquisition of basic information about each member of the patient's family. Similar data about the general population is obtainable from the Bureau of the Census. With these two sets of data, one may analyze family composition in relation to admissions to psychiatric facilities and determine rates of admission among families with specified characteristics.

Death Rates

Preliminary findings of a study of deaths among mental hospital populations were presented. This study was based on data submitted by the Model Reporting Area States in 1955. It compared age-specific and age-adjusted death rates from various causes among mental hospital populations in specific

diagnostic categories with corresponding rates for the general population. The data indicated that the death rates were considerably higher in the hospital populations than in the corresponding general populations.

One of the major difficulties this study faced was the choice of a suitable denominator for the computation of hospital death rates. Two types of rates were computed: a central rate using the average number of resident patients as a denominator, and a terminal rate using an estimate of the number of patients under treatment during the year as a denominator. Each of these rates answers a slightly different question. The most serious disadvantage of the central rate is that in certain patient groups it could exceed unity. The disadvantage of the terminal rate is that the reporting of data on the annual movement of populations in mental hospitals is not sufficiently complete to provide an adequate count of the number of patients under treatment during the year.

A new study of mental hospital death rates was therefore proposed which would be conducted during a period centered around the 1960 population census. Attention would be focused on only certain mental diagnostic groups and certain causes of death, and data would be collected over a 3-year period to insure stability of the resulting rates. Representatives of several States expressed interest in this study and it was agreed that details would be worked out during the year.

Statistics in Canada and Great Britain

Delegates from Great Britain and Canada described their mental health statistics programs and compared their problems with those in the Model Reporting Area. They expressed the desire to obtain international comparability of mental health statistics, but it was generally agreed that the first step will be to obtain comparability within each country.

Other Problems

In view of the interest in staffing patterns of mental hospitals, the conference recommended that the forms currently used for reporting personnel data be revised so as to include fewer

1. No prior admission to any inpatient psychiatric facility.

2. Prior admission to an inpatient psychiatric facility in the State system, to which the patient is now being admitted, in the following categories: (a) State and county hospitals, (b) institutions for the mentally defective, and (c) psychopathic hospitals.

3. Prior admission to other inpatient facilities as follows: (a) State psychiatric facility in other States, (b) Veterans Administration hospitals, (c) private mental hospitals, and (d) all other inpatient psychiatric facilities, including psychiatric services of general hospitals.

Under this definition, patients who have until now been considered first admissions because their inpatient experience occurred in hospitals not listed in the register will be classified as having had prior admissions to such hospitals. This definition will provide a greater amount of information than the current one and will permit a more meaningful comparison of admissions to the State mental hospital systems.

The committee on definitions also proposed that the definition of "transfer" be revised to take into account the increasing interchange of patients between hospitals for the mentally ill and institutions for the mentally defective. Transfers would continue to be defined as movements of patients between hospitals within a single State system without a break in custody, but the State system would be redefined to include public mental hospitals (exclusive of Veterans Administration hospitals) and public institutions for mental defectives within the State. This proposal was also approved by the conference.

Model Reporting Area States

Representatives from the following States are members of the Model Reporting Area for Mental Hospital Statistics.

Arkansas	Louisiana	Oklahoma
California	Michigan	Pennsylvania
Connecticut	Minnesota	Texas
Illinois	Nebraska	Virginia
Indiana	New Jersey	Washington
Kansas	New York	Wisconsin
Kentucky	Ohio	

Cohort Studies

Eleven of the States in the Model Reporting Area submitted data showing the proportion of patients released from, dying in, or retained continuously in public mental hospitals within the first 12 months following admission. Based on these data and on statements submitted by each of the 11 States concerning the laws, policies, and other factors which may affect admission or release from the public mental hospitals in their States, a draft of a monograph was presented at the conference for discussion.

The monograph had four major objectives: first, to illustrate the mechanics and difficulties of conducting a study that requires careful definitions and analysis and the cooperation of 11 independent governmental organizations, widely separated geographically; second, to present data on the probabilities of release, death in the hospital, or continuous residence in the hospital for specified periods of time following first admission in different State mental hospital systems; third, to discuss the problems in interpreting interstate comparisons of these data; and fourth, to delineate the types of data, methodology, and special studies needed to obtain more meaningful interstate comparisons. Thus, considerable emphasis was placed in the monograph on the limitations of the data and the problems inherent in their interpretation.

The conference members agreed that the monograph would be a valuable reference for people working in the mental hospital field, that the draft be submitted for approval to the commissioners of mental hygiene of the 11 States, and that it be published as soon as possible.

A proposal was presented to the conference for a more detailed cohort study in which members of the Model Reporting Area might participate. Based on the experience gained in the monograph study, the cohort research would involve: (a) a more precise definition of the starting cohort in terms of previous psychiatric care, type of commitment, and date of admission; (b) stratification of patients in the cohort by marital status, age, sex, mental diagnosis, and urban and rural residence; (c) development of specific criteria for classification of patients at time of release; and (d) followup

Concepts in the Prevention of Hepatitis

The following remarks on hepatitis are quoted from a panel discussion in the Proceedings of the Third Conference of the Industrial Council for Tropical Health, April 16-17, 1957, published by the Harvard School of Public Health this year.

DR. GEOFFREY EDSALL: I did not get a clear picture with regard to our working concepts of the prevention of hepatitis. I know perfectly well that any working concepts, other than the waterborne outbreak in Delhi and a few other similar bits of evidence, might be just as vulnerable as some of the theories and practices that Dr. Thomas C. Chalmers outlined. But for something to go away with, I would like to propose this if only in order to see it knocked down: Assuming the control of hepatitis is essentially identical with the control of dysentery—that is, putting it in the simplest possible language, if it were a fecal disease, transmitted by water and other related mechanisms—could it be prevented by exactly the same types of sanitary approaches? I have stated this arbitrarily, in order to provide a target, and I would be interested in the comments of the panel.

DR. JOHN R. PAUL: I wish I could dispose of this in a few plain words. Let us assume that the same principle may be followed. There are, however, a number of points that might be different. For instance, you mentioned the epidemic in Delhi, India, where a member of our department was fortunate enough to be present. This alert person in the water supply division realized that sewage was getting into the water supply, so he did all the things he knew to prevent a catastrophe; namely, he stepped up the chlorine to—I can't give you the figures—levels which normally should take care of bacterial infections. I'm not sure that it would take care of everything, but this was singularly effective, it would seem, in preventing any outbreaks of dysentery and typhoid in the city.

Anyway, the water supply suddenly had be-

come 50 percent sewage. The chlorination was effective in that there were no outbreaks of typhoid fever, but was singularly ineffective in preventing hepatitis. It would seem as if this high percentage of chlorine had killed off most pathogens, if not all of them, but had not a lethal effect on hepatitis virus.

The other feature that might possibly be emphasized, in which this might differ from the control of the enteric diseases we mentioned before, is that this is a virus highly resistant to heat. When it comes to boiling water or washing utensils or cleaning mess kits, my guess—although no better than anyone else's—is that it does seem that a little more vigorous heat treatment seems to be indicated than would normally take care of other agents.

DR. EDSALL: I am glad you brought out the quantitative differences. I didn't phrase my statement right. The qualitative differences were the same, but as you pointed out, quantitatively we are dealing with a much tougher agent to kill.

DR. RODNEY A. YOELL: Some of this has undoubtedly arisen or originated from the practice of doctors who give vaccinations for travel agencies. They use the multiple-dose vaccine. In other words, they buy the 10-dose typhoid and 10-dose cholera in bottles. I checked up about 20 of them, and only 3 were autoclaving their needles. I am wondering if something couldn't be put in the serum or vaccine as a warning or a preventive. Apparently it gets into the vaccine and stays there, because these people get vaccinated, then they come to San Francisco, and just before they get to Japan, they have the virus.

CHAIRMAN JOHN C. SNYDER: I think you have called attention to the importance of adequate heat sterilization, and this really deserves emphasis. I am sure that there are numerous examples that all of us could draw upon, pointing up this feature.

and more specific categories of personnel and data on turnover of personnel which would show the number employed at the beginning of a year, the number added during the year, the number leaving employment during the year, and the number employed at the end of the year. It was further proposed that State personnel officers assist in formulating the necessary classifications and definitions.

Statisticians find that interpreting interstate comparisons of expenditure data is complicated by differences in accounting procedures among States. For this reason, a committee was appointed to work with State finance officers and the Council of State Governments, which is also considerably interested in clarifying this matter in order to develop more meaningful reporting of expenditure data.

In a discussion of the interpretation of trends in the population movement of public mental hospitals, it was pointed out that existing data on population movement do not indicate the specific groups of patients in which changes are occurring, nor do they permit an analysis of changes in relation to possible causative factors.

With this as background, a proposed form was examined for the annual reporting of

population movement according to age, sex, length of hospital stay, and two diagnostic groups: schizophrenia and diseases of the senium. This form permits an analysis of changes in population movement within groups defined simultaneously by the four variables. While some of the representatives indicated that these tabulations would require changes in their existing procedures, most of them agreed to prepare them on a trial basis after certain modifications in the form had been made.

Regional Meetings

A report was given covering the proceedings of the Third Midwest Conference on Mental Health Statistics, held in Lansing, Mich., on October 2 and 3, 1957. The first three meetings of this group were aimed primarily at developing interstate comparability of mental hospital data in the midwest. At the third meeting it was suggested that it would be desirable to conduct some small-scale research projects on a regional basis. Accordingly, a committee was appointed to develop suggestions for such projects and to present these plans at the next meeting of the group in October 1958.

CDC Courses in Environmental Health

The following courses in environmental health will be offered at the Communicable Disease Center, Atlanta, Ga., during 1958-59:

Epidemiology and control of milkborne diseases. October 20-24. Review of epidemiology, emphasizing its use in the control of milkborne diseases. Epidemiology problems will be presented to the class for solution.

Milk pasteurization controls. November 12-14. Instruction in principles and control of milk pasteurization and demonstration of testing procedures, with the class responsible for the testing. Fieldwork will be performed on full-scale operating equipment.

Milk sanitation—operational. February 9-20. Comprehensive coverage of health and sanitation problems in the safe handling of milk and milk products, designed for public health personnel administering such programs.

Epidemiology and control of foodborne diseases. May 25-29. A multidiscipline course emphasizing epidemiological principles in the control of foodborne diseases. The class will work in groups and use a team approach to solve an epidemiological problem.

No tuition or fees will be charged for these courses. Priorities for admittance must be restricted to qualified personnel because the size of each class is limited. All applications must be received at least 2 weeks before the course begins.

Application blanks and further information may be obtained through local and State health departments, Public Health Service regional offices, or by writing to Chief, Communicable Disease Center, Public Health Service, 50 Seventh Street, N. E., Atlanta 23, Ga.

Concepts in the Prevention of Hepatitis

The following remarks on hepatitis are quoted from a panel discussion in the Proceedings of the Third Conference of the Industrial Council for Tropical Health, April 16-17, 1957, published by the Harvard School of Public Health this year.

DR. GEOFFREY EDSALL: I did not get a clear picture with regard to our working concepts of the prevention of hepatitis. I know perfectly well that any working concepts, other than the waterborne outbreak in Delhi and a few other similar bits of evidence, might be just as vulnerable as some of the theories and practices that Dr. Thomas C. Chalmers outlined. But for something to go away with, I would like to propose this if only in order to see it knocked down: Assuming the control of hepatitis is essentially identical with the control of dysentery—that is, putting it in the simplest possible language, if it were a fecal disease, transmitted by water and other related mechanisms—could it be prevented by exactly the same types of sanitary approaches? I have stated this arbitrarily, in order to provide a target, and I would be interested in the comments of the panel.

DR. JOHN R. PAUL: I wish I could dispose of this in a few plain words. Let us assume that the same principle may be followed. There are, however, a number of points that might be different. For instance, you mentioned the epidemic in Delhi, India, where a member of our department was fortunate enough to be present. This alert person in the water supply division realized that sewage was getting into the water supply, so he did all the things he knew to prevent a catastrophe; namely, he stepped up the chlorine to—I can't give you the figures—levels which normally should take care of bacterial infections. I'm not sure that it would take care of everything, but this was singularly effective, it would seem, in preventing any outbreaks of dysentery and typhoid in the city.

Anyway, the water supply suddenly had be-

come 50 percent sewage. The chlorination was effective in that there were no outbreaks of typhoid fever, but was singularly ineffective in preventing hepatitis. It would seem as if this high percentage of chlorine had killed off most pathogens, if not all of them, but had not a lethal effect on hepatitis virus.

The other feature that might possibly be emphasized, in which this might differ from the control of the enteric diseases we mentioned before, is that this is a virus highly resistant to heat. When it comes to boiling water or washing utensils or cleaning mess kits, my guess—although no better than anyone else's—is that it does seem that a little more vigorous heat treatment seems to be indicated than would normally take care of other agents.

DR. EDSALL: I am glad you brought out the quantitative differences. I didn't phrase my statement right. The qualitative differences were the same, but as you pointed out, quantitatively we are dealing with a much tougher agent to kill.

DR. RODNEY A. YOELL: Some of this has undoubtedly arisen or originated from the practice of doctors who give vaccinations for travel agencies. They use the multiple-dose vaccine. In other words, they buy the 10-dose typhoid and 10-dose cholera in bottles. I checked up about 20 of them, and only 3 were autoclaving their needles. I am wondering if something couldn't be put in the serum or vaccine as a warning or a preventive. Apparently it gets into the vaccine and stays there, because these people get vaccinated, then they come to San Francisco, and just before they get to Japan, they have the virus.

CHAIRMAN JOHN C. SNYDER: I think you have called attention to the importance of adequate heat sterilization, and this really deserves emphasis. I am sure that there are numerous examples that all of us could draw upon, pointing up this feature.

Reflecting the profound changes in therapy of the past decade, treatment of tuberculosis patients is shifting from the specialized to the general hospital. According to a VA physician, the trend is to be encouraged, for general hospital treatment not only is feasible but may be conducive to improved care.

Treatment of Tuberculosis in a General Hospital

WILLIAM B. TUCKER, M.D.

FOR ABOUT 75 years tuberculosis patients requiring hospital treatment have received care primarily in hospitals specializing in the treatment of this disease, usually designated as sanatoriums. As the result of the impetus given the sanatorium movement in the Adirondacks, by Dr. Edward Livingston Trudeau, the public came to associate treatment of tuberculosis with presumed benefits of the geographic location of sanatoriums. Ironically, it has now been established that it is not the geography or climate of such institutions that is beneficial, but other aspects of their treatment programs, principally close supervision by those familiar with the disease and a certain degree of rest and regularity of routine. It is now apparent that the results obtained in sanatoriums could have been achieved quite as well in general hospitals or in specialized tuberculosis hospitals located in cities and associated with general hospitals.

Recently, following profound changes in the treatment of tuberculosis, there has begun a trend toward care of tuberculosis patients in

general hospitals. The majority of sanatoriums, built during the great wave of providing tuberculosis beds in the early decades of this century, remain geographically isolated to a considerable extent. Modern communications have narrowed the gap in distance and time between sanatoriums and medical centers, but relatively few tuberculosis hospitals are integrated parts of centers providing complete medical care.

It is difficult to estimate how many patients now are receiving care for tuberculosis in general hospitals. The directory of tuberculosis hospitals and sanatoriums formerly published by the National Tuberculosis Association every 3 or 4 years, which could be a source for such information, has not appeared with figures later than those for 1953. There are no plans for publishing another directory in the immediate future because the picture is changing so rapidly that any tabulation would be out of date before it came from the presses.

Nevertheless, let us consider such figures as are available for the United States. By 1953 or 1954, the period of peak demand for tuberculosis hospitalization, there were 108,000 tuberculosis beds in the United States. (In all these figures I am excluding beds for tuberculosis in mental hospitals or penal institutions.)

Dr. Tucker is director of the Tuberculosis Service, Veterans Administration. He presented this paper, with minor modifications, at the 9th Annual Conference of the Tuberculosis Institute of Chicago and Cook County, in Chicago, on March 20th, 1958.

for in these the individuals would remain as charges regardless of their tuberculosis.) At the turn of the century, when there were 200 deaths per 100,000 population, there were less than 10,000 tuberculosis beds, or 1 bed for each 18 annual deaths. By World War I the number of beds had reached 50,000, a ratio of 1 bed for each 3 annual deaths. Many of us remember the drive of the 1930's and 1940's to have enough beds for a ratio first of 2 beds per annual death, then 2.5, and finally 3, in all States. As progress was made in avoiding tuberculosis deaths, the number of deaths declined from 165,000 early in the century to 100,000 in the middle 1920's, to 50,000 in the middle 1940's, and to 20,000 in the middle 1950's (in spite of great population growth), and the ratio of beds to deaths finally reached 5:1 for the Nation and more than 10:1 in many States.

During all of this period the majority of beds for tuberculosis were in sanatoriums. In 1953, 92 percent of the 108,000 beds were so located.

Furthermore, the majority of the 9,000 tuberculosis beds in general hospitals were there for certain specific limited purposes, not for routine long-term care. The Index of Hospitals and Sanatoria With Tuberculosis Beds, published by the Public Health Service annually in recent years, is sprinkled liberally with the following kind of footnotes for general hospitals listed as providing care of tuberculous patients: diagnosis only, surgery only, diagnosis or short-term care only, temporary hospitalization only pending transfer, less than 5 tuberculosis beds, all patients are transfers in for rehabilitation, takes only ambulatory patients, and no specific number of beds set aside for tuberculosis.

Because data for the United States as a whole are difficult to obtain in recent years, I shall turn to the experience of the Veterans Administration. Since World War II the VA has cared for approximately one-tenth to one-eighth of all the tuberculosis patients of the country, roughly the same proportion as the ratio of veterans to total population. In 1954, the year of peak demand, there were 14,200 beds for treatment of tuberculosis in hospitals, excluding 2,300 for the care of the psychiatric tuberculous. Of these 14,200 beds, 8,200, or

58 percent, were in tuberculosis hospitals, the remainder being in general medical and surgical hospitals.

Prior to World War II a far higher percentage were in tuberculosis hospitals. The fortuitous coincidence of the opening of a number of new VA general hospitals with a greatly increased demand for tuberculosis care among veterans immediately after the war permitted the establishment of many units or sections for tuberculosis patients in general hospitals. Furthermore, the lessening of the demand for beds since 1954 has made it possible to effect adjustments generally favoring locations where more complete medical care is available. By 1957, the VA had approximately 11,600 beds for tuberculosis patients (other than in mental hospitals). Of these, 5,200, or 45 percent, were in general hospitals. The trend is continuing in the VA, and it probably will not be many years before more than half of the veterans requiring treatment for tuberculosis in VA hospitals will receive it in general hospitals.

These gross figures, moreover, do not tell the whole story. Just as an increasing proportion of the care of the tuberculous is being provided in what are officially designated as general hospitals, so have officially designated tuberculosis hospitals in the VA increasingly become in fact general hospitals. There is an almost continuous spectrum among the 173 VA hospitals, with respect to beds for tuberculosis, from 100 percent for nontuberculous conditions to 100 percent for tuberculosis. In fact, if the 4 VA "tuberculosis hospitals" in which more than 50 percent of the patients have nontuberculous diseases are added to the VA's general hospitals, these hospitals in 1957 cared for more than half the VA's total tuberculosis patients (6,000 out of 11,600 beds).

Reflection of Treatment Changes

What does this changing picture with regard to where patients with tuberculosis are cared for reflect?

It reflects the most rapid changes in the treatment of tuberculosis since it was established 75 years ago that tuberculosis is generally a curable disease. Treatment methods have changed drastically since the discovery of

specific drugs. Streptomycin has been generally available for 11 years; isoniazid for less than 6. Yet it was not until about 4 years ago that the clear superiority of prolonged drug treatment, replacing many other forms of therapy, was established.

Nearly everyone is aware of the declining demand for tuberculosis beds in the United States and of the closing of many sanatoriums, including Trudeau Sanatorium, the bellwether of them all, a few years ago. What is not so generally realized is that the number of individuals requiring treatment has diminished very little, or not at all, in recent years. In the Veterans Administration, for example, there was no decrease in the last 3 years in the number of veterans admitted to VA hospitals for treatment of active tuberculosis: there was in fact a 2 percent increase. During the same period there was a 16 percent decrease in the average number of patients hospitalized for tuberculosis. These apparently conflicting figures can be explained only in one way: the same number of patients are being treated for a shorter period of time in the hospital on the average. In the VA the average has decreased from slightly less than a year to a little more than 8 months. At the same time, as has been true generally throughout the country, the percentage of deaths has decreased drastically, and the percentage reaching "inactive" stage has increased, so it is clear that the shortening of hospitalization has not resulted in less effective control of the disease.

I shall try briefly to characterize the changes that have occurred in less than a decade.

Bed rest used to be the *sine qua non*, the essential; today complete bed rest is employed only for the seriously ill patient, and much more freedom of physical activity within the hospital is permitted, and even regarded as beneficial.

Collapse therapy, such as pneumothorax, thoracoplasty, and pneumoperitoneum, was once widely employed; today these procedures are relied upon less and less, with resectional surgery playing a more prominent role.

Formerly the return from a period of severely restricted activity to a more or less normal life was prolonged and gradual, usually extending, in the hospital and out, over a period

of several years; furthermore, many individuals were advised permanently to change their occupation. In contrast, today the transition from hospital to full-time activity can be much more rapid, and it is seldom that a change in occupation, even for manual laborers, is indicated.

The principal element permitting these changes has been the effective use of drugs. (The preceding applies primarily to the care of patients with pulmonary tuberculosis. Patients with certain other forms of tuberculosis, as of the kidneys or the bones, also fit this pattern, but need supporting consultant services to a greater extent.)

When we speak of general hospitals, we usually think of private hospitals where the majority of care is for relatively acute medical or surgical conditions, requiring relatively brief periods of hospital care. What may not be generally realized is that in such hospitals rather drastic changes are occurring also. As our population gradually grows older, on the average, it is more susceptible to the diseases described as chronic, which require longer periods of medical care. The need for long-term care has become so acute in many communities that an entirely new movement, the home medical care plan, has arisen to relieve the increased hospitalization demands, principally for the more chronic medical conditions.

Thus it is, in recent years, as a broad generalization, that "acute" hospitals have come to be more "chronic" in the care they provide, while such a "chronic" disease as tuberculosis has come to be more "acute" in its hospitalization requirements. It is principally because of this gradual merging in the function of these two types of hospitals, formerly so divergent, that it is possible for general hospitals to consider caring for tuberculosis patients.

Two other major trends in the field of tuberculosis need to be mentioned. One is the increasing complexity of the medical care of tuberculosis. More tuberculosis patients are in older age groups, susceptible to other diseases of the elderly, so that more access to specialized consultation services is required than formerly. There is much more need for extensive laboratory work, not only that of tuberculosis bacteriology, but also that associated with drug treat-

ment and with the management of related nontuberculous conditions. And, as has been mentioned, there is need for access to the now highly specialized branch of surgery, thoracic surgery, chiefly of the resective, or excisional, type. In brief, the best care of the tuberculosis patient today can be given only where many diverse supporting medical and allied disciplines can be brought to bear. These usually are available in general hospitals. They also have been brought successfully to many tuberculosis sanatoriums through the extensive use of consultants. But clearly the greater the geographic separation the more difficult this integration.

The other trend has to do with the number of physicians interested in the tuberculosis field. It is sad and ironic but true that for many decades a majority of the physicians caring for tuberculosis patients were those who themselves acquired the disease, recovered from it, and were advised to practice the more sheltered brand of medicine to be found within a sanatorium. The control of the spread of tuberculosis has been so great, fortunately, that now far fewer physicians are placed in this position. While accurate figures are not available, it is my impression that the supply of physicians to care for tuberculosis has decreased in recent years at a greater rate than the decrease in the number of patients hospitalized.

The training of physicians has much to do with this decrease. Today it is rare that the internist completing his residency training elects to enter the field of tuberculosis per se. He often is interested in the field of pulmonary diseases, which includes tuberculosis, but he is usually unwilling to limit his practice exclusively, or even to devote a really large part of it, to the care of tuberculosis.

These and other facets of the changing picture of tuberculosis make it almost inevitable that in the future an increasing proportion of the care of tuberculosis patients will be in "general" hospital settings.

Answers to Objections

It has been my experience, in discussing the feasibility of caring for tuberculosis patients in general hospitals, for many individuals to

think at first of the difficulties to be overcome. It has also been my experience, in three separate general hospitals, that it can be satisfactorily demonstrated, to hospital administrators, to boards, and to others, that the advantages are real and that potential disadvantages are not in fact as great as they may seem.

One of the first problems to be mentioned, and perhaps the principal one, is contagion. Certainly tuberculosis continues to be a communicable disease. However, of a group of 100 tuberculosis patients, today, with effective drug treatment, only 25 to 40 (depending on how serious is the disease among the patients admitted) are infectious at any time, instead of the vast majority, as formerly. Today the average tuberculosis patients become "negative" in 4 or 5 months or less after the start of treatment. Thus "isolation precautions" are not necessary for the majority of tuberculosis patients. Patients may be separated into "positive" and "negative" groups by rooms or by wards, with isolation precautions restricted to the former and much more freedom permitted the latter.

There is also the associated risk of hospital employees' acquiring active tuberculosis. In the Veterans Administration, some 100,000 hospital employees receive regular X-ray examinations each year. The new tuberculosis case rate among them has been declining progressively in all VA hospitals, but the important thing to report is that the risk is not greater, in the VA, in tuberculosis hospitals than in general hospitals. Furthermore, among about 60 general hospitals in the VA caring for tuberculosis patients, in which the percentage of patients hospitalized for tuberculosis ranges from less than 5 percent to more than 40 percent, there is no statistically significant relationship between percentage of tuberculosis patients and rate of development of active tuberculosis. There is some risk in working in any hospital, although the risk is declining, especially as the practice of X-raying hospital patients on admission, to detect the unknown infectious case, spreads. The essential points are that the risk of hospital employees' acquiring tuberculosis is not greater in general hospitals caring for tuberculosis patients than in general hospitals not caring for them and that

it is not less in general hospitals than in tuberculosis hospitals.

A separate study made in the Veterans Administration reveals that volunteers working in VA hospitals, whether with or without tuberculosis patients, run essentially no risk of getting active tuberculosis. Among 20,000 examined last year, not a single new case was found.

A number of other problems in hospital management associated with the contagiousness of the disease deserve brief mention. It was once thought that many hospital facilities could not be used in common by tuberculous and non-tuberculous patients. It is now known that much less duplication is necessary than was formerly thought. Studies of library books used by infectious tuberculosis patients have not shown that they are carriers of tuberculosis germs. Separate dishwashing facilities are not necessary if proper precautions are taken in preparing dishes for washing and the washers are properly operated. Separate dental and ear, nose, and throat units do not need to be established if tuberculous and nontuberculous patients are treated at separate times and if instruments are carefully disinfected. Patients with infectious tuberculosis may safely be transported to the hospital laboratory facilities or to the X-ray department by carrying out simple and effective isolation precautions. Letters written by tuberculous patients may safely be dispatched. With moderate safeguards infectious tuberculosis patients may enjoy the privileges of hospital stores or canteen services.

These statements do not, of course, suggest that all isolation precautions may be abandoned. Quite the contrary; they are made on the assumption that such precautions are carried out meticulously when indicated, for the "positive" patient. Wearing of gowns and masks, handwashing, restriction of infectious patients to certain geographic areas, special techniques for disposal of infectious waste materials, special handling of contaminated laundry, and other special techniques continue to be needed. But it has been established that these measures do not introduce insuperable obstacles. And when these relatively minor inconveniences are balanced against the greater

advantage to the tuberculosis patient of having direct and immediate access to all the facilities of the general hospital, increasingly there is recognition that the general hospital can, and probably should, share in the care of tuberculosis patients.

One more aspect of hospital care for the tuberculosis patient should be considered, that is, rehabilitation. First, as has already been implied, extensive rehabilitation is required not nearly to as great an extent as formerly; second, retraining of tuberculosis patients for new professions or occupations is now seldom indicated; and, third, "on-the-job" training, if indicated, can now occur after a relatively short period in the hospital, while the patient is still under close medical supervision on an outpatient basis and while he is continuing to take drugs.

However, certain elements of what is commonly called rehabilitation are still desirable for tuberculous patients. While necessarily hospitalized, they need (a) diversion, (b) an opportunity to study if they so desire, and (c) entertainment. Fortunately most of these needs can be supplied through the voluntary services available to most general hospitals, and rehabilitation counselors in many States are glad to work with the staffs of local hospitals. In brief, the so-called rehabilitation needs of tuberculosis patients have now become less exacting and generally can be encompassed within the framework of the general hospital.

Conclusion

I have tried to describe broadly the changing pattern of hospital treatment for tuberculosis in the past decade; to indicate some of the reasons why general hospital treatment for tuberculosis is not only feasible but may be conducive to improved medical care; and to indicate some of the problems. Nothing I have said is to be construed as indicating that excellent care cannot be given in a tuberculosis hospital or sanatorium specializing exclusively in the care of the tuberculous. It can be, but it is more difficult. What I have tried to outline is the feasibility of the general hospital's participating in the treatment of tuberculosis patients.

I shall close by gazing a little into the future. The time will come, I feel sure, when the average, well-trained physician is as well trained in tuberculosis as he now is in cardiac or digestive disorders. The time will come, I am confident, when individuals with active tuberculosis—constantly diminishing in number—can be cared for by such a well-trained physician in a general hospital, small or large, in their home communities.

The time of course may come when we shall

not have to worry about treating tuberculosis at all! But I cannot envision that event in the predictable future. Tuberculosis remains the No. 1 infectious disease in this country. I do believe that the general hospital will play an increasingly prominent role in its control, but only if the current sound medical and public health principles continue in force. Care in the general hospital will, for a time, supplement other tuberculosis control measures; ultimately it may become the mainstay of our efforts.

Seminars in Dental Public Health

Seminar courses in public health dentistry for dentists employed full or part time in local public programs have been the major activity of the dental public health unit established at Harvard University in December 1956. An initial course, lasting from January through May 1957, consisted of 10 two-hour sessions. For the 1957-58 academic year, the course was expanded to 18 two-hour sessions over a 9-month period.

The Harvard dental public health unit is an outgrowth of efforts by the division of dental health of the Massachusetts Department of Public Health to provide assistance in public health dentistry for the more than 200 independent local dental health programs in the State. Located at the Harvard School of Dental Medicine, the unit is directed and staffed by Harvard faculty members. It receives financial support and consultative service from the State health department.

Following an introductory session on public health, the course covers such subjects as biostatistics, epidemiology, fluoridation, nutrition, health programs in relation to cultural patterns, health education, organization of medical and dental care, and dental program planning. All sessions are held in the evening from 7 to 9 o'clock. In addition to the specified number of lecture-discussion sessions, each course has included a visit to a water filtration plant.

Trainees in the first course numbered 11.

Nine were selected from among a group of local public health dentists and dental health directors, and 2 came from the Council on Dental Health of the Massachusetts Dental Society. All the participants were awarded certificates of satisfactory completion.

Besides conducting seminars, the Harvard unit offers consultation on technical subjects related to dentistry for public health dentists in local programs and serves as a diagnostic and treatment resource for referred cases presenting medico-dental problems beyond the scope of local resources.

The unit is directed by Dr. James M. Dunning, lecturer on public health dentistry at the Harvard School of Dental Medicine. Faculty members of both the University's School of Dental Medicine and its School of Public Health have taken part in the seminars.

Following this lead set by Massachusetts, the Hartford (Conn.) Health Department is currently planning, under the direction of Dr. Leonard F. Menczer, a similar seminar program to begin in January 1959. Letters have been written to the directors of each of the schools, hospitals, and clinics where dentists are employed to apprise them of the proposed undertaking and to enlist their cooperation. The Greater Hartford Area has some 11 agencies using the services of dentists, and the number of dentists in these agencies may be as high as 50.

publications

Housing Codes—The Key to Housing Conservation. Volume 1. Code enforcement problems and recommendations. Volume 2. Minimum housing standards ordinance. Volume 3. Administrative guide for local programs. 72, 79, and 34 pages, respectively.

A study of housing codes and their administration in a representative sample of communities in New York State and elsewhere, sponsored and financed jointly by the New York State Division of Housing and the Urban Renewal Administration of the Housing and Home Finance Agency, has resulted in this three-volume report.

Following a summary of the study findings in volume 1, volume 2 sets forth a recommended ordinance establishing minimum requirements for existing housing. The ordinance is intended for enactment by the local legislative body. In volume 3 are recommendations concerning methods of adoption, enforcement, and inspection.

A limited number of copies are available from the Bureau of Community Development, State Division of Housing, 270 Broadway, New York 7, N. Y.

Primer for Paraplegics and Quadriplegics. *Patient Publication No. 1; 1957; 38 pages; 50 cents.*

The nature of paraplegia and the consequent adaptations of normal living that become necessary are described in simple terms. Clothing, diet, and excretory functions of the paraplegic are fully discussed.

A chapter prepared by the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare, describes services offered paraplegics through State rehabilitation agencies, giving the broad conditions of eligibility, a general outline of methods, and a discussion of employment prospects.

This manual, the first of a series regarding specific disabilities, is directed to all persons disabled by

damage to the spinal cord and to their families. Copies may be obtained from the Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, 400 E. 34th Street, New York 16, N. Y.

✓ **Animal Disease and Human Health.** *Annals of the New York Academy of Sciences; vol. 70, art. 3; June 3, 1958; pages 277-761; \$5.00.*

A publication on comparative medicine that should prove useful to the professions of the medical sciences, this series of 40 papers discusses diagnosis, control, and treatment of diseases which can be transmitted from lower animals to man.

The monograph is the result of a conference held by the New York Academy of Sciences in collaboration with the Communicable Disease Center, Public Health Service, Atlanta, Ga., September 11-13, 1957. All papers were prepared by persons well versed in their respective specialties, and the publication was edited by James Lieberman, conference chairman.

Copies may be purchased through the Executive Director, New York Academy of Sciences, 2-East Sixty-third Street, New York 21, N. Y.

Health Statistics From the U. S. National Health Survey—The statistical design of the health household-interview survey. *PHS Publication No. 584-A2; 1958; 41 pages; 35 cents.*

The initial statistical design of the continuing health household-interview survey, which is a major phase of the program of the U. S. National Health Survey, is described. The book contains chapters on background and objectives, summary of structure of the household-interview survey, survey procedures, and sample design.

There are eight appendixes: illustration of content of initial basic household questionnaire, estimating equations, sampling and measure-

ment errors, stratification of primary sampling units, the sampling allocation problem, illustration of drawing PSU's and households into the sample, randomizing assignments, areas, and weeks, and selected statistics about the survey.

Nursing Resources—A progress report of the program of the Division of Nursing Resources. *PHS Publication No. 551; 1958; 43 pages; 30 cents.*

A chart book with text, this brochure describes the changes that have occurred in the practice of nursing during the last few decades and how the Division of Nursing Resources is helping to solve some of the problems created by these changes.

The 20 charts illustrate various aspects of nursing, including the Nation's supply of professional and nonprofessional nursing personnel, their distribution in the population, and their training and utilization.

✓ **School Health Services—A selective review of evaluative studies.** *Children's Bureau Publication No. 362; 1957; by Bronson Price; 149 pages; 45 cents.*

Significant studies of school health services made during the last 30 years are reviewed in this book. The purpose is to help research workers and professional workers in school health services evaluate current programs and determine future needs.

The studies fall into five major groups, according to the methods employed: use of statistical rates as study criteria, health survey findings, use of expert judgment, developing study samples and reexamining the children, and experimental research approaches. Practically all the studies relate to health services in the elementary schools, where by far the greatest effort in school health services is concentrated.

Rehabilitation of Deaf-Blind Persons—A manual for professional workers. *Vol. 1; 1958; 246 pages; \$3.70*

Technical aspects of rehabilitation of the deaf-blind are covered in this

series of papers dealing with problems of communication, social services, general health and sight-hearing, vocational adjustment, and recreation services for the deaf-blind. The principal methods of communication with the deaf-blind, including the recently developed International Standard Manual Alphabet recommended for worldwide adoption, are described and evaluated.

Prepared as an outcome of a 2-year study by the Industrial Home for the Blind and the Office of Vocational Rehabilitation, the manual will be followed by more detailed and technical papers on the same general subjects.

Copies may be obtained from the Industrial Home for the Blind, 57 Willoughby Street, Brooklyn, N. Y.

Bibliography of Medical Reviews. *National Library of Medicine; Vol. 3; 1958; 205 pages; \$1.00.*

References to approximately 2,885 review articles, 585 of which are not duplicated in the *Current List of Medical Literature*, are contained in this third volume of the bibliography.

The subject section follows the general pattern of the previous volumes, and the number of references cited in the review article is given in parentheses at the end of the reference. In addition a detailed cross-reference structure and a complete author index are provided.

Health Statistics From the U. S. National Health Survey—Preliminary report on disability, United States, July–September 1957. *PHS Publication No. 584-B4; 1958; 30 pages; 30 cents.*

Estimates of person-days of restricted activity, including days people were confined to bed, stayed home from work, or only cut down on their usual daily activities, are presented in 7 general tables supported by 3 graphs and 18 detailed tables. Explanatory text includes appendixes containing technical notes on methods and definitions of terms.

The number of persons with chronic limitations of activity or mobility is estimated by the degree

of limitation. The data are derived from continuing household interviewing carried on for the Public Health Service by the Bureau of the Census.

Research Publications of the National Heart Institute—January 1953–June 1958. *PHS Publication (unnumbered); 1958; 110 pages; 40 cents.*

A listing of scientific papers and abstracts by staff members of the National Heart Institute, this bibliography documents the more recent work in the conduct of their intramural research.

The publications are listed chronologically by year, and alphabetically by senior author, under the name of the research unit in which the studies were performed. The listing thus provides, for scientists and others interested, a record of progress made through investigations carried on at the institute.

State Occupational Health Programs. *PHS Publication No. 605; 1958; 41 pages; 30 cents.*

Abstracts of State program plans for occupational health are grouped by States and regions. This booklet also summarizes major health needs and administrative problems pertinent to occupational health, as expressed by State program directors. Selected administrative information for each State, including placement of responsibility for occupational health in the health department and staff assigned to the program, is shown in tabular form.

Plans prepared by the majority of the States cover a 2-year period beginning with fiscal year 1957. In some States air pollution control activities were included, but these are not described in the abstracts.

The Training Program of the National Institute of Mental Health, 1947–1957. *PHS Publication No. 603; 1958; 65 pages.*

A comprehensive review of the training program at the National Institute of Mental Health during the first decade of operation, this report covers its basic philosophy, a survey of accomplishments during

the past 10 years, a detailed description of the training program in 1957 and 1958, and an appraisal of mental health training needs during the next 5 years.

The report also contains a historical account of the development of the program and an analysis of the research fellowship and career investigator programs. In addition, 11 appendixes provide comprehensive analyses of the expenditures for the various training programs with complete information about the relative proportions expended for teaching personnel, trainees, and other items.

Indians on Federal Reservations in the United States—A digest, Portland Area. *PHS Publication No. 615, part 1; 1958; 50 pages.*

Brief summaries of selected information about each Federal Indian Reservation in three States of the Portland Indian Health Area—Idaho, Oregon, and Washington—comprise this digest.

The population groups, their social characteristics, including homes, education, and income sources, and their health status and services are discussed. Included also is a description of the location, ownership, and topography of the reservation land.

Successive parts of this digest will be published, each pertaining to a jurisdictional area of the Division of Indian Health, Public Health Service.

Public Health Nursing Service to Families—A collection of case studies. *PHS Publication (unnumbered); 1958; 145 pages.*

Case studies from official health agencies have been compiled to illustrate the variety of cultural, racial, and economic groups served by public health nurses and the diversity of services provided. Each of the 19 presentations includes a brief description of the family unit, a summary of its medical problems, and a transcript of the nursing notations.

Although this monograph was prepared primarily as an aid for teaching public health nursing concepts and practices to student and graduate nurses, it should be useful also to

publications

public health nursing supervisors and administrators in evaluating the comprehensiveness of nursing care, analyzing the usefulness of the nursing record, and demonstrating program accomplishments.

Guide to Russian Medical Literature. *PHS Publication No. 602; 1958; edited by Scott Adams and Frank B. Rogers; 89 pages; 40 cents.*

Prepared to assist investigators unfamiliar with the indexing, abstracting, and bibliographic services, this book contains chapters on western sources of information about Russian medical literature, on the Russian systems for indexing and abstracting, on translation activities and services, and on the collections of Russian medical literature in the National Library of Medicine. Three translations of Russian papers on medical libraries and the medical printing industry of the U.S.S.R. are also included.

The guide was prepared cooperatively by the National Library of Medicine and the National Institutes of Health.

The Nation's Health Facilities—Ten years of the Hill-Burton hospital and medical facilities program, 1946–1956. *PHS Publication No. 516; 1958; by Leslie Morgan Abbe and Anna Mae Baney; 181 pages; \$1.25.*

Progress in planning and constructing health facilities with Federal assistance through the Hill-Burton program is reviewed. The status of each type of health facility reported by the State plans is given as of July 1956. These plans include nearly all types of health facilities in the Nation except Federal facilities and doctors' and dentists' private offices.

Much new analytical material, particularly for general hospitals in metropolitan areas, general hospital service regions, and psychiatric

units in general hospitals, is included. For convenient reference, the book also has limited data for January 1, 1958, in a supplement to the appendix. Eleven charts and 45 tables appear throughout the book.

Sewage and Water Works Construction, 1957. *PHS Publication No. 608; 1958; by William H. Abbott, Kenneth H. Jenkins, and Elsie Gibson; 15 pages; 20 cents.*

Construction contract awards during calendar year 1957 for sewage treatment plants, collecting sewers, and water systems are contained in this report. The tables present data arranged by States, population groups based on community size, and contract size groups.

Directory of State and Territorial Health Authorities, 1958. *PHS Publication No. 75; 1958 revision; 99 pages; 35 cents.*

Revised as of May 1958, this directory lists by State the name of each health department, the officer in charge, the principal organizational units within the department, and the names of officials directing those units. Included also are officials of other State agencies directing grant-in-aid programs of the Public Health Service and of the Children's Bureau grant program for crippled children's services.

Personnel of the Public Health Service in charge of functions closely associated with State health departments are listed in the appendix.

Farmers' Expenditures for Health Care in 1955. *Agriculture Information Bulletin No. 191; by Alvin L. Bertrand and Donald G. Hay; 1958; 33 pages; 25 cents.*

Data collected in the survey of farmers' expenditures in 1955, conducted by the Department of Agriculture and the Bureau of the Census, indicate the items of health

care which farm families buy and their expenditures for each.

Average family expenditures and aggregate outlays are tabulated by region and geographic division, and variations are analyzed. The report also examines the relation of health care expenditures to selected socioeconomic factors: economic class of the farm, age of the operator, total living expenses, and family size.

Bibliography of Space Medicine. *PHS Publication No. 617 (Public Health Bibliography Series No. 21); 1958; 49 pages.*

Almost 400 references have been selected for this bibliography from the indexes and catalogs of the National Library of Medicine and from leading aviation, aviation medicine, and astronautical publications. They are arranged in broad subject classes, in inverse chronological order, and alphabetically by author.

The subjects include sealed cabin problems, acceleration and deceleration, fractional and zero gravity, cosmic radiation, survival problems, psychological and social problems, ground crew problems, and extra-terrestrial aspects.

Highlights of Heart Progress, 1957. *PHS Publication No. 595; 47 pages; 25 cents.*

Detailed, yet understandable to the layman as well as the professional, this booklet describes program developments and research studies conducted and supported by the National Heart Institute during 1957.

Research findings on 20 subjects in such major heart disease categories as atherosclerosis and coronary heart disease, high blood pressure, and heart failure are reported. Surgery and new knowledge and methods are discussed in the remaining 27 items.

Vital Statistics of the United States, 1956—Mortality data. *NOVS Publication, vol. II; 525 pages; \$1.25.*

Twenty tables of final detailed mortality data for 1956 are presented in this volume. The material

is tabulated according to places of occurrence and residence, month of occurrence, color, race, sex, age, and cause for persons in the United States, each State, metropolitan and nonmetropolitan counties, each county, and certain cities.

Volume II of this annual publication is published prior to volume I.

✓ **I. Health Insurance Coverage by Age and Sex, September 1956.** *Research and Statistics Note No. 18; May 21, 1958; 6 pages.*

II. Characteristics of the Population with Hospitalization Insurance, September 1956. *Research and Statistics Note No. 14; May 27, 1958; 7 pages.*

III. Health Insurance in the Population 65 and Over. *Research and Statistics Note No. 17; June 11, 1958; 9 pages.*

IV. Hospital Utilization by Persons Insured and Uninsured in September 1956. *Research and Statistics Note No. 19; June 23, 1958; 9 pages.*

✓ **V. The Relationship of Marital Status to Hospital Utilization and of Insurance Ownership to Methods of Paying for Hospital Care, Year Ending September 1956.** *Research and Statistics Note No. 25; July 23, 1958; 9 pages.*

A series on the extent of health insurance protection in the United States prepared by the Social Security Administration, these five notes are based on replies to questions added to the Current Population Survey.

The data have been analyzed by age, sex, race, and marital and labor status. Differences between the uninsured, the insured, and the entire population in these demographic characteristics are examined. Income data are included in the note dealing with the aged.

Copies of the notes may be obtained from the Division of Program Research, Social Security Ad-

ministration, Department of Health, Education, and Welfare, Washington 25, D. C.

✓ **VD Fact Sheet, 1957.** *PHS Publication No. 341; 1958; 14th revision; 22 pages.*

Basic statistics on venereal disease incidence, prevalence, and treatment are provided for persons interested in public health and venereal disease problems.

Other statistics relate to the estimated annual cost of uncontrolled syphilis, mortality and insanity caused by syphilis, health department casefinding activities, morbidity by age, effect of syphilis on pregnancy, and incidence of reactions to penicillin in a venereal disease clinic population.

This information supersedes any previously published data.

Refuse Collection and Disposal—An annotated bibliography, 1956–1957.

PHS Publication No. 91 (Public Health Bibliography Series No. 4, Supplement C); by Edward R. Williams; 48 pages; 35 cents.

The references comprising this supplement have been annotated to facilitate the exchange of information in both the research and operational phases of refuse sanitation. They are arranged in sections which correspond to the various administrative and operational phases of the entire field of refuse collection and disposal.

✓ **Communicable Disease Center—Report of activities.** *PHS Publication No. 599; 1958; 69 pages.*

A synthesis of the major activities of the Communicable Disease Center for the fiscal year 1956, this report describes the scope, nature, and interrelationships of the Center's cooperation with States and Territories to provide assistance in epidemics and natural disasters; consultations, demonstrations, and

program reviews; and laboratory services.

The book is arranged along the broad categories of the Center's pattern of operation. The major portion is devoted to field and laboratory investigations of diseases. Training activities are outlined under four specific headings.

✓ **Proceedings, 1957 Annual Conferences—Surgeon General, Public Health Service, and Chief, Children's Bureau, with State and Territorial health officials.** *PHS Publication No. 580. 1958. 90 pages.*

The proceedings cover addresses and actions at the three 1957 conferences of the Surgeon General and the Chief of the Children's Bureau with the State and Territorial health officers, mental health authorities, and hospital and medical facilities survey and construction authorities.

Recommendations and resolutions of the participating State and Territorial officials pertain to such subjects as mental health, medical facilities, home accident prevention, patient care in nursing homes, rehabilitation, air pollution, and implications of the social security programs.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared by other Federal agencies.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

THE EXPERIMENTAL TRANSMISSION OF POLIOMYELITIS TO THE EASTERN COTTON RAT, *SIGMODON HISPIDUS*

By CHARLES ARMSTRONG, *Senior Surgeon, Division of Infectious Diseases, National Institute of Health, United States Public Health Service*

Through the courtesy of Dr. Max Peet, of the Department of Surgery, University of Michigan, we received on August 28, 1937, a sample of brain and cord from an 18-year old boy, one of several bulbar cases of poliomyelitis which occurred at Lansing, Mich., during that summer. A strain of virus was recovered from the material which has now been through 15 monkey passages and which clinically, and pathologically as reported by Surgeon R. D. Lillie, is apparently a strain of poliomyelitis. Neutralization tests with this virus have not been done.

On November 8, 1937, several species of rodents, including a cotton rat received through the courtesy of Dr. A. Packchanian, of the National Institute of Health, were inoculated with a fourth monkey passage of the virus. The cotton rat remained apparently well until the twenty-fifth day, when it appeared nervous and tremulous. On the following day it was paralyzed in both hind legs and was sacrificed.

Pathologist R. D. Lillie, who has made all the pathological studies, reported "polioencephalitis." Eleven cotton rats were inoculated with this strain of poliomyelitis virus during the winter of 1938, of which rat No. 9, inoculated on February 14, became paralyzed in both hind legs 29 days later. Brain and cord emulsion was passed to rat No. 13 and symptoms appeared on the sixteenth day following day there was paral-

SEPTEMBER 22, 1939, pp. 1719-1721

In this paper Dr. Charles Armstrong reported the first successful transfer of the Lansing strain of poliomyelitis to rodents. Later (December 29, 1939, pp. 2302-2305) the strain was passed from the cotton rat to the white mouse.

Investigations of Staphylococcal Infection Acquired in Great Britain's Hospitals

R. E. O. WILLIAMS, M.D.

In his brief account of the work on staphylococcal infection in British hospitals during the past 10 years, Dr. Williams offers the following observations:

"Practically all the staphylococci responsible for epidemics are resistant to penicillin and most are resistant to other antibiotics as well. It is possible that by now selection by antibiotic treatment has increased the proportion of virulent strains as well as of antibiotic resistant strains, but I do not think there is good evidence that the resistant strains of today are fundamentally more virulent than the sensitive strains of yesterday. If the use (or misuse) of antibiotics has increased the incidence of staphylococcal cross-infection, this is more likely to be due to our reliance on drugs instead of asepsis for preventing infection rather than to any malign effect of the antibiotics in selecting especially virulent staphylococci. If there were no cross-infection, the development of drug resistance would have a relatively limited importance."

IT IS convenient to start a review of British investigations on the hospital spread of staphylococcal infection by recalling the work of Devenish and Miles (1). They studied a

Dr. Williams, director of the Streptococcus, Staphylococcus, and Air Hygiene Laboratory, Public Health Laboratory Service, London, England, delivered this paper at the National Conference on Hospital-Acquired Staphylococcal Diseases held in Atlanta, Ga., on September 15, 1958. He wishes to acknowledge the benefit derived from numerous discussions with colleagues, especially Drs. R. Blowers, R. A. Shooter, O. M. Lidwell, and M. Patricia Jevons.

series of postoperative infections in a surgical unit and were able to trace them quite clearly to the introduction of staphylococci, at the time of operation, by one surgeon who was a healthy nasal and skin carrier. This study was important not only because it showed the potential danger of a healthy carrier of staphylococci but also because it was the stimulus for a great deal of basic work on the frequency with which the cocci were carried by normal adults (2, 3).

There was in Britain a great deal of interest in hospital infection during the war years. At that time the hemolytic streptococcus was regarded as the important cross-infecting organism, and there were at first only sidelong glances at the staphylococcus. The streptococcus offered a simpler problem than the staphylococcus has proved to be, even without considering antibiotics, because its rarity in fresh wounds and relative rarity in the respiratory tract made it immediately clear that cross-infection, not self-infection, must be involved. The work during the war was important in showing that streptococcal cross-infection of surgical wounds could be controlled by closing channels of contact infection, by no-touch dressing techniques, and by the maintenance of an aseptic routine in the wards as rigorous in its way as those already regarded as standard in the operating theater (4).

For the protection of most wounds from streptococci, attention to contact infection seemed to suffice. But with burns this was not enough, and Colebrook (5), in pioneer work at Birmingham in 1950, supplemented the no-touch dressing technique with chemoprophyl-

THE EXPERIMENTAL TRANSMISSION OF POLIOMYELITIS TO THE EASTERN COTTON RAT, *SIGMODON HISPIDUS HISPIDUS*

By CHARLES ARMSTRONG, *Senior Surgeon, Division of Infectious Diseases, National Institute of Health, United States Public Health Service*

Through the courtesy of Dr. Max Peet, of the Department of Surgery, University of Michigan, we received on August 28, 1937, a sample of brain and cord from an 18-year old boy, one of several bulbar cases of poliomyelitis which occurred at Lansing, Mich., during that summer. A strain of virus was recovered from the material which has now been through 15 monkey passages and which clinically, and pathologically as reported by Surgeon R. D. Lillie, is apparently a strain of poliomyelitis. Neutralization tests with this virus have not been done.

On November 8, 1937, several species of rodents, including a cotton rat received through the courtesy of Dr. A. Packchianian, of the National Institute of Health, were inoculated with a fourth monkey passage of the virus. The cotton rat remained apparently well until the twenty-fifth day, when it appeared nervous and tremulous. On the following day it was paralyzed in both hind legs and was sacrificed.

Pathologist R. D. Lillie, who has made all the pathological studies, reported "polioencephalitis." Eleven cotton rats were inoculated with this strain of poliomyelitis virus during the winter of 1938, of which rat No. 9, inoculated on February 14, became paralyzed in both hind legs 29 days later. Brain and cord emulsion was passed to rat No. 13 and symptoms appeared on the sixteenth day following day there was paralysis.

SEPTEMBER 22, 1939, pp. 1719-1721

In this paper Dr. Charles Armstrong reported the first successful transfer of the Lansing strain of poliomyelitis to rodents. Later (December 29, 1939, pp. 2302-2305) the strain was passed from the cotton rat to the white mouse.

CONVENTIONAL (turbulence)

These figures are high enough, but to them must be added the quota from epidemics in which the attack rates may be much higher. The only measure we have of the frequency of such epidemics is the number of incidents from which staphylococci are sent for type identification. In 1957, the Staphylococcus Reference Laboratory at Colindale, London, received specimens from 30 outbreaks with 10 or more patients affected. The laboratory serves an area with a population of $13\frac{1}{2}$ million, and it is sent material only from a proportion, perhaps a small proportion, of the epidemics that occur.

Nor do wound infections and infant sepsis exhaust the list of staphylococcal infections that are acquired in hospitals. Pneumonia is certainly not uncommon: we observed 5 cases of pneumonia in the course of a surgical ward epidemic having 17 cases of wound infection and an attack rate of about 2 percent in the same ward in a subsequent 8-month period free from epidemics (10, 11). Urinary infections and skin lesions among adult patients are also seen.

Postoperative staphylococcal diarrhea has been observed in a number of hospitals, both in sporadic cases and in epidemics (12), but the incidence is too low to obtain a general attack rate.

In some epidemics, particularly those due to

PISTON

staphylococci of phage type 80/81, skin infections among the staff are very common (13).

Air Hygiene in the Operating Room

The institution of the "wound book" for recording the incidence of postoperative sepsis led Shooter and his colleagues to an elegant study on air hygiene in the operating room (8). Over a period of 8 months, 9 percent of clean surgical wounds developed postoperative sepsis, and the staphylococci from these patients fell into many different phage types. The operating room was at the top of the hospital and its ventilation was such that air was sucked into the room from the adjoining corridors and ultimately from the wards. It seemed likely that this air stream carried staphylococci from the wards into the operating room, where they could enter the wounds. This idea was confirmed when adjustment of the ventilation to provide a positive pressure of air within the operating room was followed immediately by a decrease of from 9 to 1 percent in the incidence of sepsis apparently due to theater infection. There was also a striking reduction in the number of bacteria found in the air of the operating room.

Blowers and his colleagues (14) had earlier studied an operating room in a thoracic surgi-

laxis and the use of an air-conditioned room for performing the dressings.

At about the same time Miles and I were investigating infections in small industrial wounds (6). Sepsis was usually due to staphylococcal infection, and the staphylococci were very commonly those carried on the patient's skin before the infliction of the wound. We thought that in these small wounds streptococci indicated hospital infection, staphylococci self-infection.

Any idea that this distinction would prove generally true was soon shattered when it was observed that penicillin-resistant staphylococci were becoming increasingly common in surgical wards, and that the resistant strains differed in phage type from the sensitive strains previously infecting the patients and probably did not arise as variants of them (7). The fact that staphylococcal cross-infection in the wards became evident when the staphylococci had acquired the mark of drug resistance has led some to think that cross-infection is a new phenomenon, characteristic of the drug-fast strains. I do not think there is any reason to believe this, although reliable statistics of incidence for pre-antibiotic days, as for the present, are difficult to find and to interpret.

Prevalence of Hospital Infection

Determination of the prevalence of hospital infection is the first question that faces us today. Generally, the incidence of sepsis cannot be satisfactorily discovered from a review of ordinary hospital case records. Several hospitals have therefore devised special sepsis records. The surgical unit at St. Bartholomew's Hospital in London keeps a "wound book" in the operating room (8). In this book all operations are recorded and it is noted whether the wounds are healing satisfactorily or developing sepsis.

Elsewhere similar records have been kept in the wards (9). Many hospitals have systems for reporting cases of infection to the laboratory or to an infection control officer, usually the hospital's medical bacteriologist, whose function it is to keep a special watch on all aspects of infection throughout the hospital. It is our feeling that systems that simply re-

quire notification of cases of infection are less likely to give complete records than those that demand recording of the outcome, whether infection develops or not. Most hospitals now have an infection control committee, which includes representatives of all the important departments within the hospital, and in many cases also includes the medical officer of health of the district in which the hospital is situated.

The development of these systems is relatively new, and little information has yet been published on the prevalence of staphylococcal infection. For this reason the Public Health Laboratory Service in England and Wales has instituted a survey of postoperative infection in selected hospitals in different parts of the country. All clean operations performed by one surgical team in each hospital will be observed for 1 year, and the mode by which wounds heal will be assessed jointly by the surgeon and the bacteriologist. Preliminary results from three hospitals, for example, show from 5 to 9 percent of clean surgical wounds developing staphylococcal infection with clinical sepsis (B. Moore and R. J. Henderson in personal communications). The rates for some of the other hospitals are mostly about 5 percent.

A number of surveys have also been made of the incidence, apart from epidemics, of skin sepsis in newborn babies. We made one such study in a maternity hospital 2 years ago and in a 6-month period found that 15 percent of the babies developed some staphylococcal lesion (conjunctivitis or skin sepsis) before discharge. Dr. M. H. Hughes, in an unpublished survey in a hospital in South Wales, found an incidence of 14 percent, but lower rates have been observed by others. The incidence of breast abscess is very difficult to determine because the disease so often develops after the patient's discharge from the hospital (even when this is at the 10th to 12th day as it is in Britain) and is treated by a different physician. Hughes found an incidence of 1 percent, and others have reported very similar rates (B. Wilkinson in a personal communication, 1958).

It seems that, even apart from recognized epidemics, 5 percent or more of clean operation wounds and 10-15 percent of newborn babies develop septic lesions due to staphylococci.

such nurse who started outbreaks in several wards in which she worked.

In our own studies in a surgical ward at St. Bartholomew's Hospital (10, 11), we thought that we could distinguish particular patients who were actually or potentially dangerous. For example, it seemed very likely that a sharp epidemic in 1956 was started by a patient with a staphylococcal pneumonia; he was probably the source of several ward infections and he may well have infected the member of the surgical team who became a carrier and certainly infected many patients at operation.

In later studies, we recognized a number of patients who were especially apt to disperse their staphylococci. In some cases there seemed to be a good reason for this aptitude, such as urinary infection with incontinence or pneumonia with a tracheotomy. But the individual who contaminated air to the greatest degree was a healthy carrier.

We were so impressed by the ability of some infected patients to disperse their staphylococci that we rigorously isolated in a separate room any patient infected by what appeared to be a dangerous staphylococcus, which we provisionally took to be one resistant to tetracycline. The physical isolation was, of course, supplemented by a very strict isolation-nursing technique, great care being taken that no material that had been near the patient was used in the ward without sterilization. On 6 separate occasions in 2 years of this regimen we have been able to isolate all patients with septic lesions as well as healthy carriers known to be infected with supposedly dangerous types. Only once did infection spread to another patient, probably because of a breakdown in the isolation. On one occasion when we isolated the septic patients but had insufficient space to isolate all the carriers, two secondary cases occurred; the strain was of phage type 80, which is known to be very communicable.

The isolation nursing of infected surgical patients has in general been curiously neglected; yet, when we see the extent to which infected patients can contaminate the ward, it surely seems ridiculous to nurse them among patients with susceptible wounds that have to be redressed daily. One of the most valuable contributions that hospital administrators can

make to the solution of cross-infection may well be the provision of really adequate isolation facilities in all wards, sufficiently equipped to simplify the routine of isolation nursing.

Spread of Infection in Maternity Wards

Although infection is commonly introduced into a maternity ward by a nurse who is a carrier, it seems clear that subsequent spread is often from one baby to another. In seeking the route of this spread, some have stressed the umbilical stump as a reservoir. It recently became fashionable to leave the stump uncovered, and it was easy to show that in these circumstances the stump became contaminated with staphylococci as or more quickly than the nose. Jellard (26) found that if the umbilical stump was painted daily with an antiseptic dye, the staphylococcus seemed to spread less readily through the nursery. Her studies, however, were confined to the rate at which newborn babies acquired bacteria. Gillespie (27) has had a similar experience with the use of a hexachlorophene dusting powder for the umbilicus. Cook, Parrish, and Shooter (28) studied a variety of nursing techniques for their effect on the rate of nasal colonization. Although they could not reduce the rate greatly by any method, they found the best to be the reservation of individual clean gowns for the nurse's use when handling each baby, coupled with the application of antiseptic dye to the umbilical stump. We have recently found that air disinfection with ultraviolet irradiation had no effect on the nasal colonization rate, but that daily bathing with soap containing hexachlorophene might be of some use. Forfar and MacCabe (29) could detect no effect on the incidence of minor sepsis when the nurses in one of two nurseries gave up wearing special gowns and masks.

Environmental Contamination

To the bacteriologist, the ease with which staphylococci can be isolated from ward dust and from bedding and curtains is inescapable. It seems inconceivable that such heavily contaminated material should not be a reservoir for the spread of infection to patients. This thought has prompted many attempts to eliminate the contamination. The wool blanket

cal unit in which suction ventilation led to the contamination of air in the operating room with ward staphylococci. As a consequence of these studies and of the still earlier work of Bourdillon and Colebrook (15), it is now accepted that when operating rooms are built within the hospital, they need to be ventilated under positive pressure to exclude contaminated air issuing from the hospital. The rate at which the air within the room is changed must also be great enough to insure that any contamination liberated at one operation is cleared before the next operation is commenced. This usually implies a rate of 10-20 air changes per hour. Blowers has been investigating the best ways of getting the required rate of air changes with the least expenditure of energy, and he has shown that it is advantageous to bring the air in at the ceiling in such a way that it tends to descend through the room in a piston fashion, rather than by inducing turbulent mixing (see chart). This piston ventilation can be achieved by proper design of the air inlets and, in some circumstances, by using the incoming air as the principal source of heating for the room. The change from turbulent mixing to downward displacement may have another advantage. With a really steady piston effect it may be possible to protect the sterile area to some extent from contamination dispersed by the staff even within the operating room.

In several reports, Blowers has stressed how the number and activity of the staff in the operating room affect the bacterial count of the air. He showed, in one instance, that training the staff to avoid all unnecessary movement reduced the count as much as improving the ventilation did (16, 17), though the source of contamination in the two cases is different. Blowers' observations and the recent work of Hare and his colleagues (18, 19) on the dispersal of staphylococci from contaminated clothing of nasal and skin (especially perineal) carriers of staphylococci stress the importance of a rule that all persons working in the operating room should change all their clothing (which is not by any means general in Britain) or should wear some special protective suit as suggested by Duguid and Wallace (20).

The operating room air can be contaminated by ward staphylococci not only by air streams

from the ward but also by blankets and the like used to cover the patient on his journey to the operation. It is best that the patient be covered with sterilized material sent to the ward from the operating room. If he has to be transferred from the operation table directly to his bed, this should not be done within the operating room itself.

Carriers in the Operating Room

Airborne infection in the operating room is probably not uncommon, but probably it is not often responsible for epidemics of sepsis. Several epidemics of operating-room sepsis have been traced to staff members who were dangerous staphylococcal carriers. In some instances the carrier had a septic lesion as did the surgeon described by McDonald and Timbury (21); in others the carrier was apparently quite healthy (1, 22). Knowing how widespread the staphylococci are on the skin of anyone with a septic lesion and knowing the frequency of accidental glove-puncture during surgery, it is not surprising that a surgeon with a boil infects the patients on whom he operates. The healthy carriers present a much greater problem, because we know that some 50 to 70 percent of all hospital staff carry staphylococci in the nose and 20-40 percent carry them on the skin. Why then do they not cause epidemics more often? It may be that some carriers are qualitatively different from others: the surgeon described by Devenish and Miles (1) seems to have been a particularly profuse carrier on the skin of his forearm. Or it may be that the staphylococcus has to be virulent: the carrier described recently (10) certainly had a staphylococcus of more than average virulence, as judged from its behavior in the ward.

Carriers in the Wards

The peculiar ability of some individuals to spread their staphylococci has also been recognized as responsible for the spread of infection in wards. In maternity departments there have been several outbreaks of infection (23, 24) in which a single nurse who was a carrier of the epidemic type of staphylococcus seemed to be responsible for many cases of infection, and Jellard (25) has recently referred briefly to one

patients who developed postoperative sepsis, and 7 of them were nasal or skin carriers of staphylococci before the operation. One might think that when we reach the stage at which we can attribute so much of the postoperative infection to the patients' own preoperative staphylococci we may be nearing our goal. But we need to beware, for patients who are in hospitals for any time before an operation often become nasal carriers of the hospital staphylococcus (37) and this hospital strain may be the one that infects the wound.

The records of the staphylococci sent to us at Colindale for typing reveal an interesting fact on the frequency of carriers among the staff. In 4 years we typed material from staff and patients in 94 separate epidemics. Altogether about 18 percent of the staff carried the type of staphylococcus that was locally epidemic, but there was a striking difference between epidemics due to staphylococci of phage group 1, with some 25 percent of the staff who were carriers, and those of other phage groups, with 3-13 percent carriers (see also 38). The notorious type 80 (or 80/81) did not differ in this respect from other types in phage group 1. Apart from type 80, which occurs in all sorts of hospitals, phage group 1 strains are not often epidemic outside maternity hospitals. The results suggest that widespread nasal carriage of the epidemic strains among hospital staffs is not common enough to justify general nasal disinfection as a routine and that it is more likely to be relevant in maternity hospital outbreaks than in outbreaks in surgical wards, unless the infecting strain is type 80.

Chemoprophylaxis and chemotherapy of the wounds have been widely used, but too rarely precisely assessed; and only in the management of burns has a serious attempt been made to integrate antibiotic treatment with the work on the prevention of cross-infection (39). There is a great need for more detailed work to discover just what can be prevented by prophylaxis, and to what extent treatment can, at least, prevent an infected wound from being a dangerous source of cross-infection.

Epidemic Types of *Staphylococcus aureus*

It used to be thought that all strains of coagulase-positive staphylococci were similar in

virulence, but this idea can certainly be held no longer. On the other hand, the recent world-wide spread of one type known as 80, or 80/81 (or 52/44A/42C/47C, and the like), has led some to think that it is only this strain that is important and strains of all other types can be neglected. This idea is likewise quite untenable.

Our studies in the surgical wards emphasized the different capabilities of different strains of staphylococci. From all sites in the ward, in an 8-month survey, some 186 different strains of *Staphylococcus aureus* were isolated, but only 13 of these caused disease, and only 3 caused disease in more than 1 patient. Some strains seemed to have remarkably little virulence. One was present in the air of the ward, often in large numbers, for 6 months, but never caused a secondary case of sepsis and only colonized 3 patients' noses. Another was present in the ward for 8 months without causing any secondary cases of sepsis, although it colonized the noses of 57 persons. In contrast, the strain present in the same ward in the previous year caused 34 cases of wound sepsis and other disease in a 2-month period. It was widespread in the air and dust, but it colonized only two noses.

I have made an analysis of the phage types of staphylococci from septic lesions sent to Colindale in the 4 years 1954-57. Altogether we had 1,131 independent strains (counting all the strains from any one epidemic as one strain), 638 from surgical units and 493 from maternity units. A great many different types could be recognized, but some 20 types or groups of closely related types were each represented by 10 or more strains. Among the 1,131 independent strains, 178 were, in the particular time and place, epidemic strains, and 69 percent of these were found in no more than 7 types. Type 80 had the highest proportion of epidemic strains. This type was equally common in maternity and surgical units; but other common epidemic types were 52A/79 and 71 in maternity units and 75/77, 47/53/75/77, and 7/47/53/54/75 in surgical units.

In Britain, as elsewhere, type 80 has spread rapidly in the last few years; at Colindale we had specimens from 5 or 6 epidemics in each of the 3 years 1954-56, and from 21 epidemics in

offers the greatest problem, for dust and fluff are readily dispersed from its surface, and ordinarily it is laundered at too low a temperature to kill staphylococci. Indeed washing is so harmful to blankets that it has commonly been practiced as rarely as possible.

As a legacy from earlier work on streptococcal infection we had the method of oil impregnation of wool blankets to prevent dispersal of the bacteria, without killing them (30). Later Blowers and Wallace (31), following earlier work by Rountree and by Barnard, devised a simple method for disinfecting wool blankets during laundering, using a nonionic detergent for washing and a cationic detergent for disinfection. This process, which effectively kills staphylococci—though not *Pseudomonas pyocyanea* or *Mycobacterium tuberculosis*—and which does little harm to the blankets, has been quite widely adopted. Other methods are also being investigated by which wool blankets can be disinfected safely.

But clearly a blanket that could withstand the laundry temperatures used for linen and cotton material would have great advantages. Blowers, Potter, and Wallace (32) tested three materials: loose woven cotton, thick toweling, and Terylene, all of which can be boiled. Both cellular cotton and the toweling make good blankets and can be recommended.

It is therefore perfectly possible to provide patients with sterilized bedding, but it is still not known just how much good we may expect to do by this. The effect of sterilized bedding on the air contamination in the wards has been tested somewhat, but there is very little work yet on the incidence of sepsis. Nevertheless, the general view seems to be that it is undesirable to harbor in the ward a large pool of staphylococci on blankets and curtains and that their regular disinfection is likely to reduce the incidence of sepsis.

We have made several studies of the bacterial content of the air of a surgical ward (11). We found a basal level of about 0.1 particle containing *Staphylococcus aureus* per cubic foot. Much higher counts (0.5 to 5.0 particles per cubic foot) were found, even during relatively quiet periods in the ward, when one of the patients was an active disperser, but such high counts were not constantly associated with the

occurrence of cases of sepsis due to spread within the ward, although it is true that a peak occurred whenever spread took place.

Treatment of the Carrier State

The inanimate hospital is an enormous reservoir of staphylococci derived from infected patients and from carriers, but staphylococci do not multiply in dust or on bedding and it seems more rational to attempt to control dispersal by an attack on the breeding places rather than on the resting places. Gould (33, 34) has made a series of studies of the antibiotics and disinfectants applied to the nose to eliminate the carrier state. He finds that applying a cream containing, for example, 0.5 percent neomycin and 1 percent chlorhexidine (Hibitane) for 7 to 14 days rids most carriers of detectable nasal staphylococci for a period of a few weeks. This method used by several workers has often been successful for treating nurses who have become carriers during an epidemic (35), but some carriers seem to be quite resistant to this form of treatment, even though their bacteria are sensitive to the antibiotic in vitro. Gould and Allan (36), working on the assumption that hospital infection with staphylococci was derived from carriers among the staff, treated all the staphylococcal nasal carriers on the staff of a small hospital with a tetracycline cream for 1 week and found that the incidence of hospital infection decreased strikingly during the period following this treatment. On the other hand, Gillespie (27) has proceeded on the assumption that the patients are (or become) nasal carriers and infect their own wounds. He therefore applied an antibiotic cream to the patients' noses from the time of their admission to the ward and throughout their stay, and the frequency with which staphylococci were isolated from open wounds fell from about 15 to about 3 percent. The incidence of clinical sepsis was not reported.

Clearly, these two concepts need further study. In our first year's work in the surgical ward at St. Bartholomew's, Dr. Shooter and I could find no evidence that the wound infections were derived from either the patients' or the staff's noses; infection seemed to be from one infected patient to another. On the other hand, during the past year we have studied 15

helped by a laboratory test of virulence so that the potential initiators of epidemics could be isolated. Otherwise, it seems that our only hope is to regard all persons, whether surgical patients, babies, or staff, with staphylococcal lesions as having virulent strains, and to treat them in strict isolation as one would cases of infectious disease. It would also be wise, when possible, to isolate known carriers of strains resistant to many antibiotics. The hospital also needs to have a recording system sensitive enough to recognize quickly any increase in the prevalence of infection and someone with clinical authority to scrutinize the records and initiate the investigations that may be able to stem an epidemic.

Of general preventive measures, the aseptic handling of patients should receive the greatest stress. Every staff member's approach to the patient must be informed by a realization of the infectiousness of staphylococcal infection. Everything taken from the infected patient must be sterilized, and all material used for the treatment of all patients must not only be sterilized but must be kept sterile right up to the time that it is used. The provision of proper facilities and equipment is an essential contribution from the administrators; the rapid and detailed recognition of the infecting bacteria is the duty of the laboratory; but there are no gadgets and no drugs or vapors that can relieve the people who handle the patients of their perennial responsibility for handling them aseptically.

1957. Thirty percent of all the strains that we had from septic lesions in 1957 proved to be type 80, although this figure may be somewhat inflated by the general interest shown in this particular type. But even now, quite extensive epidemics due to other phage types are being seen.

Practically all the staphylococci responsible for epidemics are resistant to penicillin and most are resistant to other antibiotics as well. It is possible that by now selection by antibiotic treatment has increased the proportion of virulent strains as well as of antibiotic resistant strains, but I do not think there is good evidence that the resistant strains of today are fundamentally more virulent than the sensitive strains of yesterday. If the use (or misuse) of antibiotics has increased the incidence of staphylococcal cross-infection, this is more likely to be due to our reliance on drugs instead of asepsis for preventing infection, rather than to any malign effect of the antibiotics in selecting especially virulent staphylococci. If there were no cross-infection, the development of drug resistance would have a relatively limited importance.

Conclusion

Although some progress seems to have been made in understanding what happens in hospitals, it is clear that much remains to be done. In the laboratory, especially, factors related to virulence need to be explored and in the wards all the numerous measures that are advised for the prevention of cross-infection need to be more precisely tested. For it is certain that if we prescribe too many rules their observance will be neglected.

In my opinion there is no one way in which staphylococci spread in a hospital, and there is no one prophylactic method by which spread can be prevented. The routes of infection are numerous and probably often devious, and the precautions needed are many and often complex.

Staphylococcal hospital infection is an infectious disease, with this subtlety, that while most staphylococci are, when given the best opportunity, able to produce septic lesions, relatively few of them seem able to produce

epidemics. Probably all hospitals have their endemic level of staphylococcal infections, while some, from time to time, suffer epidemics. Our preventive measures have therefore to minimize the endemic level, to prevent the emergence of epidemics, and to terminate epidemics when they occur.

It seems probable that an epidemic is usually started when an especially virulent staphylococcus is introduced into a hospital by someone who is able to disperse it readily. If we are prepared to try, it should not be too difficult to recognize people who are likely to disperse the bacteria, but we have at present no satisfactory measure of the virulence of staphylococci other than the retrospective record of what a particular strain has achieved. There is some correlation of epidemicity with phage type, but we know of many introductions of well-known virulent types into hospitals with no subsequent spread. Perhaps this means that they were not being dispersed sufficiently, or very likely there may be variations of virulence within the type. The combination of two factors, virulence and dispersal must be present; but we must hope that these two, although necessary, are not sufficient. Our preventive measures ought to be such that we can limit the spread of virulent strains, even from the profuse dispersers.

When an epidemic has started, the best approach to control it is to attempt the elimination of the epidemic strain from the hospital. This means, first, definition of the type of staphylococcus that is causing infection in the patients, and, second, a search for carriers of this type in the hospital personnel or patients. Sometimes such a search will reveal the one dangerous carrier whose exclusion terminates the epidemic. Often the search will reveal several carriers. Even though it may be possible to judge from epidemiological analysis that one is important in an epidemic of any severity, it is worth treating or excluding all of them. These searches, with the examination of fomites and the typing of all staphylococci, will often exceed the facilities of the hospital laboratory. Outside agencies, such as public health laboratories, should be equipped and ready to help in these investigations, and their help should be readily sought by the hospitals.

The prevention of outbreaks would be greatly

Prevention of chronic disease, services for long-term patients, and social programs related to their health were discussed at a recent meeting held by directors of State chronic disease programs and the Subcommittee on Long-Term Illnesses and Aging of the Association of State and Territorial Health Officers at the University of Michigan, Ann Arbor. Of the 20 papers delivered, 4 have been selected for publication here in slightly revised form.

Progress in Control of Chronic Disease

DAVID SEEGAL, M.D., and ARTHUR R. WERTHEIM, M.D.

THE MEDICAL profession's awareness of the preventive aspects of chronic illness is just coming of age. Much has already been written and said about this subject; many committees and public health agencies have pressed home salient points; and the current state of our knowledge in the field has been treated comprehensively in the volume, *Prevention of Chronic Illness*, issued in 1957 by the Commission on Chronic Illness. The impetus of past efforts now finds expression in the general acceptance of the belief that chronic disease represents the most important problem facing medicine today and in major breakthroughs in the primary or secondary prevention of certain long-term diseases. (In primary prevention, the occurrence of a disease is averted; in secondary prevention, the progression of a disease from its early, unrecognized stage to a more severe stage is halted.)

In discussing chronic diseases with physicians and medical students we find there is a common tendency to consider as chronic only

those long-term diseases not yet subject to specific treatment or to primary or secondary prevention. This attitude naturally fosters a pessimistic outlook.

Man's memory can be short and the physician is not exempt from this frailty. In the field of acute diseases, our students have to be reminded that in New York City alone there were 166 deaths from yellow fever in 1822, 5,071 deaths from cholera in 1849, and 552 deaths from typhoid fever in 1911.

The physician's memory of the advances in prevention and control of some long-term illnesses is beclouded and often dominated by our present inadequacies rather than by our past accomplishments. Unwittingly, he gives too little thought to the chronic diseases which are now preventable or controllable. These diseases represent scientific battles already won even though the strategy and tactics of the clinician and the public health officer are still required to implement the measures for their control.

Just what are these diseases? In 1949, my associates and I compiled a list of representative chronic diseases that were largely controllable, partially controllable, or uncontrollable (see table 1).

Some changes in classification might be made at this date, and some additions should be made. For example, retrolental fibroplasia should be added to the largely controllable group; dental

Dr. Seegal is professor of medicine, College of Physicians and Surgeons, Columbia University, and director, Columbia University Research Service, Goldwater Memorial Hospital, New York City. Dr. Wertheim is associate professor of medicine at the college and attending physician at Goldwater. Dr. Seegal presented this paper at the symposium.

Sanitary Engineering Courses in Radiation and Water Analysis

A course in sanitary engineering aspects of nuclear energy will be conducted at the Robert A. Taft Sanitary Engineering Center, Public Health Service, in Cincinnati, Ohio, December 1 through 12, 1958. Designed for engineers and scientists in public health, especially those in supervisory posts, the course covers the broad aspects of radiological health.

The program opens with a discussion of radiation fundamentals and instrumentation, then focuses on radiation protection, nuclear reactor operations, and measurement and evaluation of environmental radiation contamination.

During the same 2-week period, the center will give a course in chemical analyses for

water quality, for graduate chemists and professional people with extensive background in water supply and water pollution control.

Among subjects covered are: measurement of strength and effect of oxygen-demanding wastes; investigation of toxic industrial wastes, including the determination of toxicity through bioassay; characterization of synthetic organic wastes; water supply problems; and survey and administration, including basic data program.

Applications may be obtained from the Chief, Training Program, Robert A. Taft Sanitary Engineering Center, 4676 Columbia Parkway, Cincinnati 26, Ohio, or from a Public Health Service regional office.

Progress in the Control of Heart Disease

which attracted the physician's attention and care. Today the "beginnings" of long-term disease are being revealed to the doctor because of painstaking clinical, physiological, biochemical, pathological, and epidemiological studies. This new knowledge must perforce accelerate the rate of development not only of therapeutic but also of preventive measures.

Evidence now indicates the need for reappraisal of the concept that the so-called degenerative diseases of middle life are initiated about the age of 40. The average age of onset and the minimal age of onset of clinical illness (symptoms or signs) for a few of these disorders are shown in table 2. Although organ failure may be generally manifested in middle age, the data support the belief that some chronic illnesses may be recognized in early life.

Table 2. Approximate age of onset of clinical symptoms of some representative chronic diseases

Disease	Average age	Minimal age
Gout	40	6
"	32	9
"	56	26
"	38	10
Laennec's cirrhosis	55	2
Multiple sclerosis	28	5

Certainly this belief would apply to those congenital diseases in which genetic factors are obvious. There are a group of diseases in which the hereditary influence is less clearly defined; nevertheless many observers hold that genetic factors play a role in such disorders as hypertension and coronary atherosclerosis, for example.

Be that as it may, recent additions to our knowledge support the opinion that the beginnings of a number of important chronic illnesses of middle and late life can be detected in early life (see table 3).

In some of the entities listed in table 3, it has been established that the early subclinical stage may exist for years prior to the development of overt clinical disease. Screening programs would detect the defect. When possible, preventive measures could then be brought to bear.

For example, the avoidance of obesity has been suggested as a useful primary preventive measure for siblings of diabetic patients. These recommendations are particularly advisable for such individuals when they have decreased glucose tolerance. The efficacy of a restricted carbohydrate diet in such patients to prevent clinical diabetes mellitus is now being explored.

Gamma globulin administration has proved to be a useful measure in preventing recurrent

caries, paralytic poliomyelitis, certain forms of glaucoma, and some instances of the nephrotic syndrome might be added to the partially controllable group.

Clinical findings during the past few years indicate that the malignant phase of primary hypertension may also be added to the list of partially controllable chronic diseases. Low sodium diets, sympathectomy, and, more recently, the antihypertensive drugs have extended the lives of some hypertensive patients. However, data on the influence of these forms of treatment on the uncomplicated phase of primary hypertension are less convincing and at present do not justify its addition to a list of therapeutic successes. Although atherosclerosis appears in the group of uncontrolled chronic diseases, extensive laboratory, epidemiological, and clinical investigations suggest that a breakthrough may not be too far distant.

These advances have occurred in recent years. In my student days, our teachers told us there were no effective methods to control significantly such long-term diseases as diabetes mellitus, pernicious anemia, tuberculosis, any form of congenital heart disease, sprue, cirrhosis of the liver, Addison's disease, or rheumatic fever. That picture has changed and is continuing to change favorably.

These facts seem worthy of reemphasis because of some recent divergent opinions. Although the former Surgeon General of the Pub-

lic Health Service, Dr. Leonard A. Scheele, has expressed the view that the solution of critical problems in chronic disease is much nearer than is generally recognized, his optimism is not shared by all. Dr. Lowell T. Coggeshall, for instance, has been quoted as stating that "progress against chronic illness and disability is disappointingly slow."

In our view it has been surprisingly rapid. For example, witness the progress made in the control of heart disease since the turn of the century. The accompanying chart lists the eight chief causes of past and present cardiac disorders. The deflected arrows symbolize increasing control in 6 of the 8 diseases; hypertension and atherosclerosis remain.

As a fourth-year medical student, I remember seeing a child who was believed to have three disorders of the heart: a congenital lesion which I think was a patent ductus arteriosus, inactive rheumatic heart disease, and *Streptococcus viridans* endocarditis.

I wonder what would have happened if, at that time, I had asked my instructor whether each of these three diseases would be amenable to prevention or control during my lifetime. My guess is that my name would have turned up on the dean's desk with a request for a psychiatric examination.

Another aspect of prevention is the age of onset of many chronic diseases. In the past it was chiefly the "endings" of chronic illness

Table 1. Status of chronic diseases, 1949

Largely controllable	Partially controllable		Largely uncontrollable
Diabetes mellitus	Congenital heart disease	Cretinism	Certain congenital defects
Syphilis	Addison's disease	Diabetes insipidus	Certain neurological diseases
Hyperthyroidism	Certain neuroses and psychoses	Gout	Certain psychoses
Myxedema	Acromegaly	Coeliac disease	Certain neoplasms
Hyperparathyroidism	Hemophilia	Lung abscess	Chronic glomerular nephritis
Sprue	Bronchiectasis	Hay fever	Hypertension
"Alcoholic" neuritis	Trypanosomiasis	Erythremia	Arteriosclerosis

Public Health and Chronic Disease

THEODORE J. BAUER, M.D.

DURING the past 10 years the responsibility of State and local health departments to participate in control of the chronic diseases has been adequately established. During this period private physicians also have recognized their responsibilities to the chronically ill, and have made many notable contributions to early treatment and rehabilitation in order to lessen the severity of complications.

The most encouraging phenomenon during the decade of progress now ending has been the way in which private physicians and public health workers have accepted the fact that no definite means for preventing many of the chronic, noninfectious diseases has yet been developed. Instead of being discouraged or dismayed by this fact, teams of private physicians and health officers have turned to the practical task of extending activities and services designed to prevent or minimize disability in chronically ill patients and to prevent premature death.

A tremendous long-range research program has also been organized in this country, aimed at unmasking such secrets as the causes of cardiovascular diseases, cancer, and mental illness.

No one over 40 is free from some degree of disability caused by either an inherited weak link in the chain of organ systems or by the ravages of premature but otherwise to-be-expected physiological decline.

As Dr. Enrico Greppi, president of the International Gerontological Society, said at the fourth congress of the society, held in Merano, Italy (July 1957), "Old age can be considered a disease consisting of deficiencies and illnesses."

Dr. Bauer, an Assistant Surgeon General, is deputy bureau chief, Bureau of State Services, Public Health Service.

Dr. Greppi estimated the average age of onset of this "disease" to be 45.

Since every individual then has a built-in "time bomb," which must cause his eventual destruction, it would seem futile to attempt to prolong "life" indefinitely, if by "life" we mean the mere act of existence. Instead, we should accept the physiological and theological premise that mortal life is meant to end and concentrate our primary attention on the prevention or postponement of disability. We should aim at maintaining as long as possible a productive state of adjustment to a necessarily imperfect existence.

This concept or approach to the problem of chronic illness frees us from the stultifying inhibitions unwittingly imposed upon us by perfectionists. Many types of cancer and heart disease are admittedly still incurable, but this should not slow down our efforts aimed at early detection of such diseases. We can help many by such work; we can help no one by refusing to undertake such work. Our duty is clear.

We can move ahead against the chronic diseases one by one now. We can move ahead now against that complex of chronic diseases loosely lumped under the heading "aging." We can apply now what we know about secondary prevention and rehabilitation, at the same time that scientists are pursuing their research into the fundamental nature of chronic diseases.

We are aware of the difficulties experienced by public health workers in State and local health departments in launching new programs. They are often handicapped by lack of funds, by lack of personnel, and by a lack of understanding of their problems on the part of the public, legislatures, and occasionally even physicians.

However, judging by the progress already

sepsis in patients with agammaglobulinemia or hypogammaglobulinemia. Early casefinding is necessary if available preventive measures are to be instituted.

Primary prevention is not yet possible for most diseases listed in table 3, but early casefinding will serve as a stimulus for further investigation. Some measures already at hand have not yet been tested adequately. For example, since penicillamine has been reported to be an agent for the removal of copper from patients with Wilson's disease, it might be worth a trial during the precursory phase of hepatolenticular degeneration to prevent increased levels of copper in tissues and thereby possibly influence favorably the course of the disease. Furthermore, it would be of interest to learn the results of long-term probenecid administration in those siblings of patients with gout who have hyperuricemia. Long-term programs have been instituted to study the effect of mild antihypertensive drugs in individuals with a family history of hypertension and who have a hyperreactive arteriolar vascular tree.

The course of action is clear. Disease can be detected in some instances before chronic illness is clinically manifest, and widespread efforts to discover individuals in these subclinical stages of disease are necessary. Progress is being made in the development of measures both for primary prevention of disease and secondary prevention after the disease is evident.

Table 3. Common precursory findings in some representative chronic diseases

Common precursory findings	Clinical disease
Hyperuricemia-----	Gout
Cystinuria-----	Renal calculi
Decreased glucose tolerance--	Diabetes mellitus
Achlorhydria-----	Pernicious anemia
Agammaglobulinemia-----	Recurrent sepsis
Serum iron excess-----	Hemochromatosis
Pernicious anemia-----	Gastric carcinoma
Vascular hyperreactivity----	Primary hypertension
Prenatal viral infections----	Congenital anomalies
<i>Streptococcus hemolyticus</i> pharyngitis.	Rheumatic fever
Silicosis-----	Pulmonary emphysema
Intestinal polyposis-----	Carcinoma of the intestine
Cystic fibrosis of the pancreas	Chronic respiratory infection
Heavy cigarette smoking----	Bronchogenic carcinoma

Conclusions

Primary and secondary preventive measures for chronic diseases are being discovered and used with encouraging frequency.

Primary prevention is effective in such representative diseases as syphilis, tuberculosis, malaria, rheumatic fever, pellagra, amebiasis, certain forms of neoplasm, and a wide variety of illnesses associated with industrial agents.

Secondary prevention can be practiced to lessen the delayed pathology and disability which results from, for example, unmanaged or mismanaged syphilis, tuberculosis, rheumatic fever, pellagra, pernicious anemia, diabetes mellitus, and hyperthyroidism.

Epidemiological, clinical, and experimental studies on such matters as the relation of cigarette smoking to lung cancer and the role of dietary fat in human atherosclerosis are now opening possible avenues for prevention not commonly appreciated 20 years ago.

A critical review of existing knowledge indicates that in the great majority of instances the presence of chronic disease long antedates the appearance of clinical illness.

This is obvious in hereditary disorders. For example, hyperuricemia is present years before the appearance of clinical gout, and cystinuria exists long before the development of renal calculosis.

A similar "silent" or "latent" period exists in other long-term disorders (not commonly considered genetically influenced) such as hypercholesterolemia prior to the development of clinical atherosclerosis, heavy smoking before the appearance of bronchogenic carcinoma, pernicious anemia before the development of gastric carcinoma, and serum iron excess prior to the emergence of clinical hemochromatosis.

Although there is a wide range in the years in which chronic illness is first recognized, there is abundant evidence that careful clinical study will disclose the incipient stage of many chronic disorders at a much earlier age than is generally appreciated.

Since preventive measures, if available, exert optimum effects in the early and often reversible phases of chronic disease or illness, it is a matter of high priority to use preventive measures as early as possible.

to be the primary responsibility of local health departments. This responsibility includes collection of significant data needed for public education leading to public acceptance of important new local health services.

The Public Health Service is proud to be able to work with State and local health departments in making the vital transition from the control of infectious diseases to the control of noninfectious diseases and accidents.

FDA Screening for Unsafe Food Additives

Chemicals used in food processing must be proved safe by the industry before they can be sold for use in foods, under an amendment of the food and drug law enacted September 6, 1958.

Previously, the Food and Drug Administration had to prove such a chemical unsafe after the food was on the market and then bring court action to stop its sale.

Under the new law, which takes effect in March 1959, the manufacturer or promoter of the new additive must test it for safety in animals and submit test results to the Food and Drug Administration. If that agency is satisfied, it will issue a regulation specifying the conditions necessary for use. Those adversely affected by an FDA order may petition for a public hearing. An order emerging from such a hearing is subject to court review.

In addition to chemicals intentionally added to food, the law covers substances which may be expected to become components of a food or to affect its characteristics and which are not generally recognized as safe for their intended use.

For substances in use before January 1, 1958, and not generally recognized by experts as safe, industry has been given 18 months to present safety data in the absence of adverse evidence.

The law further prohibits additive use that would promote deception of the consumer or result in adulteration or misbranding. The amount of the additive fixed for use by FDA regulation will not be higher than the level required to accomplish the chemical's purpose.

The Food, Drug, and Cosmetic Act, enacted in 1938, when there were relatively few chemical food additives, required the Food and Drug Administration to discover the use of "poisonous or deleterious" additives in processed foods and to prove them injurious before action could be taken to protect the consumer. Since then, knowledge of food processing chemicals and the number of additives have advanced considerably. Testing of new additives by the Food and Drug Administration, normally requiring at least 2 years, became unrealistic in the face of a flood of new products both in use and under consideration.

Another aspect of the 1938 law was that any amount of toxicity sufficed to disqualify any chemical which could not be shown to be "required in production" or "unavoidable under good manufacturing practice." This was also unrealistic. Now the Food and Drug Administration evaluation of the safety of an additive requires considering among other factors the conditions of use, amounts used, and other related additives which may be used. As a result, many useful chemicals will be permitted if they are safe when used properly.

made in chronic disease control these handicaps can be overcome, perhaps slowly, but they can be overcome. That is the important thing.

The \$3 million increase in general health grants-in-aid to States, made available by Congress for distribution by the Public Health Service, is encouraging evidence that public recognition of the importance of the chronic disease problem has broadened. With these funds, health departments can begin demonstrating to the public the value of secondary prevention and rehabilitation. Once soundly conceived local projects are developed with Federal and State assistance, local citizens themselves will accept the responsibility for seeing that such projects are continued.

What types of projects can be started? Following are several examples that already are underway in certain States:

1. In one large midwestern city a substantial local appropriation recently was made to improve diagnostic facilities for children with rheumatic fever and to provide a mechanism for the antibiotic, prophylactic treatment of the disease to prevent the development of rheumatic heart disease.

2. In a large eastern State, the State health department has obtained chronic disease funds for local distribution. These funds, plus Federal funds, are being used to stimulate and partially support for 3-year periods a host of locally conceived projects such as screening programs in hospitals, establishment of rehabilitation services, development of home care or home nursing programs, diabetes detection, and alcoholism clinics.

3. In California, a local health officer is co-operating with the local welfare department and medical society in providing certain preventive medical services for persons who apply for old-age assistance. He is applying a modification of an old adage: "A penny for prevention is worth ten dollars for cure."

The list of such projects is almost endless: glaucoma detection, meals-on-wheels for homebound oldsters, nutrition consultation for the chronically ill, and cytological screening examinations for cervical cancer.

We are aware that no matter how badly a local public health service is needed, no matter

how logical the service may appear to be, and no matter how tangible the benefits from such a service are, the service will not be accepted overnight. Adequate education must prepare for the introduction of such programs. The skeletons of many worthwhile local chronic disease projects litter the public health trail—the skeletons of projects which were offered to local people who were psychologically unprepared to accept them.

There is one worthwhile activity that State and local health officers can engage in which will tend to prepare people for new local chronic disease projects. It is an activity that is sometimes neglected in our haste to get projects underway. I refer to the need to determine on a communitywide basis the types of illness which exist and the quantitative and qualitative importance of these illnesses. Although it is widely recognized that the diagnosis and treatment of persons afflicted with a noninfectious disease is the primary responsibility of private physicians, nevertheless private physicians do not have the means at their command to determine public health priorities for a community.

It is true that the advice of local and State public health councils and advisory committees, in which private physicians play an important role, must be sought in establishing public health priorities. Still, the data collection and analysis upon which the establishment of priorities depends must be accomplished by the State or local agency designated to do this job, namely, State and local health departments.

Should a local health department determine, as a result of a community health analysis, that heart disease is the number one health problem in the community, then it would not only be logical but essential for the local health officer to present the problem of heart disease as he sees it, in all of its ramifications, to the local medical society. The health officer at that time can pledge the assistance of his staff to the local medical society in developing or administering any project they may agree upon.

Although the diagnosis and treatment of the patient with a noninfectious disease continues, as always, to be the primary responsibility of private physicians, the diagnosis and treatment of "community illnesses" continues, as always,

not by the chronically sick. These views lead to the greatest misconception of all—that good care for the chronically sick is cheap.

These erroneous impressions have arisen because we have tried to lump together all chronic disease in the same way that we generalize about all acute disease. The difficulty lies in the fact that, for medical care purposes, acute illness has only one stage while chronic disease has several. These are, first, the active or acute phase which requires definite diagnosis and the application of definitive therapy, and, second, the rest of the natural course of the disease.

When we discuss medical care needs, facilities, personnel, and costs we must specify whether we mean the active, acute, first phase, with its great demands for highly skilled physicians and many other professional and technical people and resources, or the second phase, with its lesser demands on facilities and personnel and, therefore, lower cost.

When a chronic disease hospital has low per diem rates, 1 of 2 circumstances prevail: if the patients are really sick enough to require hospital care, then they are not getting the kind of medical care they require; if the patients are getting the care they need at this low cost, then their needs must be primarily nursing or custodial, and the use of the term "hospital" is misleading. High-quality, intensive hospital care for the active phase of chronic illness costs at least as much as care for the acutely sick. The reason is clear. In order to determine or apply definitive therapy it is necessary to establish an accurate diagnosis. The diagnosis of chronic illness requires the most complex laboratory facilities, the widest range of procedures, and the most difficult and expensive X-ray examinations. For example, the X-ray procedures for diagnosing lobar pneumonia and fractures of the long bones are simple compared with those necessary to diagnose a congenital abnormality of the heart or a tumor of the brain.

Diagnosis, particularly in older people, is also difficult, because often more than one important diagnosis is involved. It is not uncommon that a patient with a tumor of the bowel may also have atherosclerosis, hypertension, or other such complications.

The same complexity prevails in the application of definitive therapy. When a healthy person is suddenly struck down with an acute illness, the treatment is often obvious, and the patient's undiminished resources can be relied upon to help him through the period of acute stress and illness.

But a patient with chronic disease is likely to be older and more debilitated and beset by complicating conditions. For example, operating for carcinoma of the bowel on a patient in his fifties or sixties requires particular care in the use of anesthesia because the patient's vital capacity may be less than it once was. His heart and blood vessels are not as supple as they were, and this must be considered when it is necessary to replace body fluids. Injudicious use of blood and fluids can lead to acute heart failure in a patient undergoing such major surgery.

In our experience at Montefiore Hospital with the complicated surgery needed by patients with chronic disease, whether it be surgery of the lungs, abdomen, or heart, we find it essential that physician anesthetists be used because such operations are always difficult and the patient's hold upon life is so delicate.

The need for the most expert skill applies equally to the surgeon, the internist, and everyone in the specialties and subspecialties of medicine. Chronic disease batters and beats its victims. All too often we first see the patients when the disease is well along, or on a second or third or even tenth or twelfth hospital admission. Their persons, their tissues, their spirits must be handled by the most gentle and the most proficient.

The requirements of great skill also extend to nursing. Without good nursing, a patient with a neurological disease or a fractured hip can become a patient with bedsores or infections which threaten his life or at least his well-being. The nurse's responsibilities include maintenance of the patient's nutrition, carrying out complex treatments, participating in the rehabilitation of the patient, utilizing the special relationship to encourage the patient in the difficult adjustment to serious illness, and many more such vital tasks. These make the care of the sick, debilitated patient with

Patient Services in Chronic Diseases

MARTIN CHERKASKY, M.D.

THE HEALTH and medical care resources and facilities generally available in our country were developed in response to the demands of acute illness. It is now inevitable and desirable that these same resources be directed toward the demands of chronic illness, which has become the main preoccupation of those in the public health and medical care fields. In determining the changes in philosophy and facilities which our medical resources must undergo to deal with this new problem, it may be worthwhile to contrast the characteristics of the acute illnesses which have occupied us in the past with those of the chronic illnesses which will occupy us in the future.

The most obvious characteristic of acute illness is dramatic onset. The healthy individual develops signs and symptoms such as sharp pain, high temperature, or coughing of blood which make clear to the patient, to the family, and to the physician that serious illness is present. In acute disease the length of illness is usually brief, most often measured in days, and the illness is marked by a crisp, definitive end point. Most often the patient makes a complete recovery, returning to good health and the activities, pursuits, and responsibilities which characterized his life before the acute illness. The characteristics of most serious chronic diseases are so different as to be almost the obverse side of the coin.

The onset of many of the chronic diseases is so insidious that often the individual will not clearly recognize that there is anything seriously wrong with him. There is no qualitative relationship between the presenting symptoms and the severity of the underlying disease.

Diabetes is a very serious illness whose sequelae are disabling and often deadly. We are all familiar with the damage to the cardiovascular system which leads to heart disease, kidney failure, gangrene of the extremities, blindness, and other complications of diabetes, and yet it is commonly stated that more than a million Americans who have the disease are not aware of it. The reason is obvious; the initial symptoms may present such small deviations from the normal that neither the patient nor his family knows that anything is seriously wrong.

By definition the duration of chronic illness is measured not in days but in weeks, months, and years. Again in distinct contrast to acute illness, chronic disease usually does not have a sharp end point with complete recovery; more often disability and handicap remain for life.

The problems that face the individual, his family, and society in the care of the chronically ill are due to insidious onset, long duration, and disability.

Medical Problems

To determine the kinds of hospital and related facilities required for the care of the chronically sick, we should closely examine the medical, nursing, and other areas of patient need. The view of chronic disease held by the general public and even by some physicians is colored by a number of misconceptions such as: chronic disease is indolent; not much can be done for a chronically sick person; the chronically sick can be cared for in lesser facilities; not as much or as high-quality doctors' care is needed for the chronically sick as for the acutely sick; the most costly and complex resources are needed by the most acutely sick and

Dr. Cherkasky is director of Montefiore Hospital for chronic disease, New York City.

you who are concerned with planning for the care of the chronically ill in a community close your eyes and dream this dream: Your community has no facilities for these people, and you can have any you believe necessary.

We all know that we will wake to the reality of facilities in the wrong place or of the wrong kind, and we must work and live within this reality. However, this exercise of imagination has concrete value. It is essential that the planners in every community have a blueprint, a dream, in keeping with the town's own cultural characteristics, needs, and resources, to show them where they should be going. Then as opportunities present themselves, they can move toward this ideal with a logical, planned program.

What are the facilities a community needs to care for the chronically sick?

1. A good general hospital with a broadened philosophy, providing not only doctors' care and nursing service but the services of social workers, and facilities for recreation, rehabilitation, and occupational therapy. In this hospital patients are not classified as acute or chronic but are cared for as their needs match the hospital's resources.

The hospital patient is a patient who requires definitive diagnosis and definitive therapy. Any patient who does not fit these criteria must be cared for elsewhere. This practice will insure that the hospital bed is used for its stated purpose. In effect hospitals should be, in toto, intensive care units. This can be brought about only by providing other institutions to which patients can be transferred when they need medical and nursing care less extensive and intensive than that provided in the modern general hospital.

2. A home care program for those patients who still require medical, nursing, and related care but who no longer require the specialized resources of the hospital. In the Montefiore Hospital home care program we have, by design, selected only patients who are quite sick, and for them we emphasize the role of the physician, the nurse, and the social worker in caring for them. We have recently undertaken, in conjunction with the Beth Abraham Home, a custodial institution, a somewhat dif-

ferent type of home care program for custodial patients. The emphasis and major cost of this program center around housekeeping and homemaking services rather than doctors and medical care.

3. The nursing home, preferably on the grounds of the hospital and certainly under the hospital's auspices for medical care and medical care supervision. This is a facility where patients, after completing the active phase of hospitalization, stay for days or weeks and receive the nursing care and, it is hoped, the aggressive rehabilitation designed to return them to the community.

4. A custodial institution for people who no longer belong in a hospital and yet cannot be cared for at home because of disabilities, handicaps, or social situations. This institution emphasizes nursing care and meets the daily needs of severely handicapped people. It would be desirable if it were on or near the hospital grounds, and certainly its medical care program should be under the supervision and direction of the general hospital.

5. An adequate outpatient department for those people who are sick but who can travel from their homes to the hospital. This activity should provide the kind of medical supervision and attention which will not only treat the immediate medical problems of these people but also will tend to keep them out of institutional facilities.

Summary

Chronic disease in its active, acute phase requires the high-quality, complex diagnostic and therapeutic facilities of the general hospital. Beyond this phase lies a varying period when lesser but continued medical, nursing, and related care is needed. A home care program, an outpatient department, a nursing home, and a custodial institution, preferably on the hospital's physical premises but certainly under its auspices, are required to meet these needs. Such broad responsibility should be assumed by the hospital because its medical and related resources are organized and available in a manner that can rarely be duplicated by lesser medical care facilities.

chronic illness the greatest challenge that nursing, with its skills, understanding, and compassion, has ever been called upon to face.

Readjusting

A serious difficulty accompanying long illness and disability is the impact of the illness upon the patient's relationships with his family and with society. Most families do not have either the financial or emotional resources to withstand the onslaught of chronic disease without help. We must recognize that chronic illness not only tends to pauperize our families but also has a destructive effect upon the family structure. Therefore, we must deal with the personal and familial emotional and social aberrations which accompany every serious long-term illness.

Here is a typical example of these difficulties. A 50-year-old man, the head of a family and the breadwinner, develops abdominal symptoms, goes to the hospital, is operated on, and is found to have a cancer of the bowel with some spread. This man not only has his life threatened by illness, but after his period of hospitalization, he is going to be handicapped and ill for the remainder of his life. Instead of being the leader and provider he will have to be cared for and provided for.

This is not only a personal catastrophe, but a catastrophe for the entire family. His wife has to assume responsibilities which he formerly bore. His children, for whom he had great hopes and aspirations, can no longer continue with their schooling but must help the family in its difficulties. One day he is a father, husband, leader, producer, giver; several weeks later the entire social structure built up over a long period of time has been shattered.

Anyone who has cared for the chronically sick has seen patients whose greatest lack of well-being, whose suffering and discomfort came, not from the physical pain and the illness which might ultimately destroy them, but from the disordered situation which the illness has produced within the family.

We physicians concerned with hospital and medical care cannot narrowly define our responsibilities as we might like to. We must define our responsibilities to fit the patient.

Since the social and emotional effects of long-term illness are vital to the well-being of the patient, the family, and the community, we must concern ourselves with this kind of problem just as effectively and aggressively as we do with organic medical problems. The social worker with her special training and skills can effectively join with the physician to meet this important patient need. The general hospital will have to broaden its philosophy and resources to deal with this aspect of illness.

Special skills are needed in medicine, physical medicine, psychiatry, social work, nursing, vocational rehabilitation, speech therapy, and many other areas to enable the patient to make the maximum use of his remaining physical, mental, and emotional resources. This concept of patient care has recently gained recognition. Every general hospital, nursing home, and home care program should undertake the rehabilitation activities appropriate to its patient population.

Among the many other activities that we must undertake in caring for patients with chronic illness is occupational therapy. This can be a very important tool if it is utilized in an intelligent manner and is integrated with other medical care. It is sad to realize that the first extended period of leisure which some people have ever had has been enforced by serious illness. In our own experience we have found that skilled occupational therapists, warm, interested, and willing to find out what kind of person the patient is, what his interests are, and the directions in which his talents or desires lie, can help patients to find the well-springs of creativity which exist within so many people unknown to themselves or others. This discovery adds a new dimension to the sick person's life and makes him feel productive and worthwhile.

Other services, such as recreation, vocational training, counseling, and job placement, are also required.

Community Program

In all communities we face the need to modify, change, and add to existing resources, facilities, and services so that we can adequately serve the chronically sick. I recommend that

others are to understand his results, it also calls for an "ungrooving" of the specialist.

The Health-Related Fields

In the broadest sense, anything that enables an individual to maintain a satisfactory level of health may be considered health related. It is advisable at this point, however, to limit discussion to economic and social services that are quite obviously health related and that can be readily integrated with those personal and family health maintenance programs that form the true basis for the public health of the community.

Counseling and group work, employment after retirement, housing, and community organization are vitally important health-related services, but two important factors underlie all of them in our approach to better public health.

One of these is education of the public, especially through adult education, without which forward movement in each specific service would probably have been much slower than it has been.

The other is our country's means of providing income through employment and through its social security system. Private and government enterprise seeks to enable the individual by means of his own resources to assume the responsibility of his own health and his family's, even through the lean years of retirement.

Social Security Programs

Conditions of employment, including the wage level of the general population, play a distinct role in maintaining the health of workers and their families. These conditions are tempered by the degree to which workers appreciate their health needs since for many health is a strictly personal matter. This is another way of saying that money without understanding of how it can best be used is not enough.

It is increasingly apparent that management and labor are sensitive to the impact of working conditions upon the health of workers, over and beyond the safety measures that are ad-

mittedly health related. The growing concern about industrial health and about plans for services to reduce the costly inroads made by chronic illness on productivity indicates the direct relationship between jobs and economic and individual health.

This concern is most practically expressed in the partnership of government, business, and industry in the Nation's social security programs. These undeniably provide the most effective bulwark we have in maintaining the health of workers and retirees. The achievements by 1957 of the past generation in social security can be looked upon with justifiable satisfaction, even pride, by everyone. The interdependence of privately and publicly supported programs of economic and social security and public health programs does not require elaboration, although voluntary agencies may overlook at times the fact that their selectivity is possible only because the public services are in operation.

It has been said that the public assistance program is one of the best means of finding cases of acute or chronic illness. This is probably true of both the disability and the old-age and survivors' insurance phases of social security, although their lack of direct social service may make casefinding a somewhat minor component of the program.

The beneficiaries of these services have as a rule low or marginal incomes. A large majority of them are middle-aged or older people, and they are ready victims of illness. Until there is a closer working relationship between security programs and community health services (both voluntary and public), we shall not realize with sufficient understanding that for children and older adults inadequate living and health facilities are sources of the increasing incidence of chronic ailments. The income of the older adults usually fails to provide proper housing, decent environment, proper nutrition, or adequate medical care when and as needed. It may be truthfully said, however, that more is done in providing medical treatment than in underwriting the other factors that might help to prevent the present, extensive need for treatment.

The results of huge expenditures of scientific effort and funds for the development of the

Health Related Services

OLLIE A. RANDALL

THE FACT that health-related services is a topic at this symposium is tangible evidence that among those concerned with health there is recognition of the fundamental kinship of health services and those services more commonly regarded as social or economic in purpose. This is a long step forward toward the time when the health and welfare of a human being and of the public of which he is an integral part will be literally indivisible.

This is not to deny that there are sicknesses of the body and mind that arise from physical causes accidental to or inherent in the environment. To trace and correct these causes is the traditional concern of public health personnel. However, sicknesses arising from social situations created by an uncongenial environment are more prevalent than ever before and have little direct relationship to the traditional focus of public health service. If we endorse the premise that the community's level of health can only be accurately measured by rating the level of health of each of its members, then the correction of socially induced illnesses becomes a logical matter for the attention of those developing or administering public health programs.

If this premise is sound, the real questions are how and through whom these economically and socially induced illnesses can be discovered and corrected. Since the basic unit of our work is the human being, the general current thinking (but not current practice) sug-

gests that treatment of the whole man is essential to the attainment of desired results or their nearest approximation, according to the means at our command.

It is perhaps trite to comment that the complexity of organized society, and the rapidity by which that complexity is constantly being compounded, is often at the root of the individual's difficulties. It is even more trite to point out that well-directed and well-balanced teamwork is required if the interrelationship of these services and interests is to be demonstrated.

The team which comes into existence through our accepting the concept of a close relationship between social and health services consists of health and socioeconomically trained personnel, and, incidentally, the individual and his family. The task of the professional members of that team is to bring together as best they can the skills of the participants whose specialties have been splintered from the originally comprehensive and central core of treatment.

With the growing number of specialties in health and health-related fields, it is no longer possible for one person to be equally well versed in all of them. But it is possible to be aware of the potential that resides in their combination for preventive and better patient care and for public health. Without merging skills, the potential is obscured or lost.

In our day, it is the chronic or long-term illness or invalidism induced by such illness, with its health, social, and economic ramifications, that professional medical personnel are called upon to diagnose, understand, and treat. This may call for further specialization, but, if

Miss Randall is a consultant on services for the aging for the Community Service Society of New York, and vice chairman, National Committee on the Aging, National Social Welfare Assembly.

strains created by this complexity, some glimmer of understanding of these attitudes becomes an essential component of health and social security programs.

If as one delegate to a governmental session forcefully commented, "Try to get a doctor to go to the home of an old chronic! It's pure nonsense to talk about it. Doctors just don't and won't go!" If this is true, whatever the reasons, doctors must come to depend on teamwork with social workers and public health nurses. For their success in working with people derives from a clear and sometimes intimate acquaintance with physical, psychological, and economic conditions in the home.

Today the public health nurse is the professional person most frequently visiting the home of chronically ill people. Generally, she is the one who is most welcome because of her easily understood and readily accepted service. If ways can be found to use her special skills at the outset of counseling, casework, or group work, we are more certain to find, as we have in the agency with which I am connected, that as health problems are minimized or resolved social situations have a way of being resolved or of resolving themselves more quickly.

Much has been said and written on the preventive aspects of group work in clubs and day centers with older people. Perhaps some of these claims can be substantiated. Experience, however, cogently indicates that professionally directed clubs and centers are seriously handicapped and limited unless they have direct ties with counseling, casework, or health services. The handicap stems usually from the need for help on physical and mental health problems; the staff is often unable to advise these people or to refer them correctly.

All this seems to point to the necessity for a greater emphasis on the physical and mental health aspects of social work, particularly in the family and group work agencies, and a greater emphasis on the social aspects of health work for health personnel.

As some of us watch service programs for older people, of whom many are handicapped by chronic illness or invalidism or are likely candidates for similar handicaps, the need for a working liaison between the branches of "comprehensive care" is distinctly highlighted.

With the current shortages of trained personnel in all fields of service, probably the most we can expect or ask for is that the desirability of such teamwork be recognized through the appointment of consultants from the field of health in social agencies and from social services in health agencies.

Postretirement Employment

If we consider postretirement employment desirable, we must find some way of making employers and employees aware of the working conditions that are conducive to maintaining health at a level necessary to meet the requirements of the daily job. We must also learn more about an individual's health potential so that we may look for positive possibilities of employment. If it is a fact that we are reaching our later years in better health than our fathers or their fathers did, let us hope that health personnel can help us capitalize on this fact through the employment of older and retired workers.

There is at present a vague, but probably not baseless, notion that with better financial underpinning of retirement, older persons are less apprehensive about it and more willing to accept it, especially if retirement has been planned for. But we have a long way to go before retirement is fully welcomed and an equally long way to go before it is sufficiently underwritten to overcome the need many older people have of working mainly for the money they can earn, regardless of psychological or social motivation.

Society must also cope with the "right to work" at any age, for the worker's sake and perhaps for the sake of society as a whole. This topic is so controversial I shall only comment that any employment program for the elderly must be closely allied with a constantly watchful health program of prevention, treatment, and restoration. The last of these has not so far been as readily available to older people, either workers or nonworkers, as actual circumstances warrant.

Whereas older people are exceptionally vulnerable to the consequences of acute disease, we are finding they are also capable of an encouraging degree of restoration if given the benefit

Salk vaccine were dramatic; it would be wonderful if there could be an equally dramatic demonstration of what similar amounts of money and scientific effort might do to prevent or minimize the high incidence of malnutrition. Thousands of malnourished children and older adults are susceptible to acute or chronic disease, but exist on assistance grants and insurance benefits that, with all the will and skill to spend wisely, are just not enough to encompass their health needs.

With the new national public assistance grants that permit some States to take advantage of funds to provide more adequate medical care for recipients of public assistance, there will be spotty improvement. But with low levels of basic assistance in many areas, little more will be accomplished than *ex post facto* treatment. Strong bodies that resist more readily the inroads of acute or chronic illness will not be built. The program, moreover, will not help the beneficiary of social insurance whose funds are sufficient to make him ineligible for even consultation regarding his health needs, but are insufficient to enable him to pay for proper care. What is vital in all this is the growing opportunity and necessity for teamwork among the arms of public services at every level of government and among official agencies and voluntary social and health services at the local level.

Money, or the lack of it, is only one factor in the health situation. Hence the Public Health Service's development of the Chronic Disease Program offers a service of tremendous value that public and voluntary social agencies should promptly seize upon. The present possibility of educating the public about the known causes of illness, the effects of untreated illness, and the wisdom of taking advantage of the vastly improved knowledge of illness is without past parallel in most communities. It is a matter of record that lectures and discussions that attract the largest number of adult listeners and interested participants pertain to health and the prevention or treatment of illness. Matters of income maintenance run a close second. The necessity of learning to protect health and income is engaging more of the time, efforts, and funds of private persons and organized groups than ever before.

Individuals and social agencies, however, need a better understanding of health and illness and the effect of the latter on their work. Health agencies have a similar need to understand the meaning of individual attitudes and family culture and their impact upon physical and mental health.

Informal and formal groups offer an unusual opportunity for the dissemination of health information; the phenomenal growth of adult education programs should be taken advantage of without delay.

Counseling, Casework, and Group Work

In recent years the direct personal relationship between an individual and the social worker whose primary concern is the well-being of that individual has also gone through some changes. It is now divided into two phases: counseling and casework. This development seems to imply that counseling is either the threshold for casework or a rather diluted form of the intensive process that characterizes casework. Whether or not this is an accurate analysis, we find more and more people, particularly the middle-aged and older people, seeking "counseling" on health matters in all kinds of service agencies. Much more must be done in training and in the development of mutual understanding between health and social services if such counseling is to be sound.

Group work, in social service, helps people adjust to each other by coming to grips with their needs as they are modified or aggravated by the needs of others and by obtaining individual satisfaction through group action. With older people, this phase of social work is used extensively, with varying success, in "golden age" clubs and in day centers.

In counseling, casework, and group work it is essential to know the person as he is in a variety of settings and relationships (as a family member, worker, and citizen at large), and as he thinks he is. There can be a real difference between the two.

Of all the settings, the most important is the home; for here attitudes about health as about other matters originate. As living becomes more and more complex, as the firmness of family ties yields to some of the stresses and

whose major objective is better service to the individual. Ultimately these measures should improve the quality of care in institutions as well as in homes, when the home-care programs are expanded.

As one observes the changing purpose of hospitals and homes for the aged and the changes in the actual use of them (nursing homes, for example, are now established as a part of the community's medical care facilities), one has

an almost overwhelming sense of the immensity of the task of community education and organization that lies ahead before we find the chronically ill patient in the right place at the right time.

Sincerely interested leadership promises a brighter future, especially if all the "relatives" of the health field join with it in order to work toward an earlier approximation of the goal of comprehensive health care.

Medical Research Expenditures in 1970

Expenditures for medical research in this country can and should be tripled to reach a billion dollars a year by 1970, a group of special consultants to the Secretary of Health, Education, and Welfare said in a recent report.

The special consultants, 10 prominent medical educators and industry research executives, were appointed in 1957 by the Secretary to advise him on long-term needs in medical research and medical education. Dr. Stanhope Bayne-Jones, formerly dean of Yale University School of Medicine, was chairman.

The consultants warn, however, that such an expansion of medical research will require a major increase in the number of physicians and other scientists—from 20,000 now to 45,000 in 1970. To make possible this increase in research staff and at the same time to provide a sufficient number of physicians to give adequate care to the expanding population, additional educational facilities will be needed, they indicate.

According to present estimates, there will be only 19,000 additional physicians and scientists for medical research during the next 12 years, 6,000 short of the estimated 25,000 additional workers needed, the report states.

The consultants believe that "it would not be in the public interest for the number of physicians in the Nation to fall below the ratio of 132 for 100,000 persons." This ratio has remained fairly constant over the past 30 years.

To maintain this ratio, they assert, would require construction of from 14 to 20 new medical schools at a cost of between \$500 million and \$1 billion. This expenditure for medical school construction would be on a much larger scale than has heretofore been contemplated.

As the consultants point out, however, even if these large funds are made available immediately, the ratio of physicians to population will fall before 1970 because of the usual lapse of 10 years from the time a school is planned until the first class is graduated.

If the Federal Government continues to provide about half of all funds for medical research, Federal expenditures would increase from \$186 million in 1957 to approximately \$500 million by 1970, the consultants estimate. Industry's share in 1970 would be more than \$300 million, and contributions of private philanthropy would amount to \$100 million.

of rehabilitation. Hence an unbiased partnership among management, labor, employment counselors, and health agencies assumes high priority for employment practices in the period currently designated as "retirement years."

Housing

Where and how people live unquestionably helps to determine the status of health they can maintain. The public health services have long been engaged in evaluating the sanitation and environmental factors which adversely affect health. Their concern not only for those facilities designed to house special health services but for housing accommodations in which people live assumes greater validity as more people, especially the chronically ill, continue to remain at home when sick.

If we take only the fact that about 95 out of 100 older people live in their own homes, either alone or in families, and relate that to the fact that the proportion of persons limited by chronic ailments is higher in the upper age brackets, it is not difficult to estimate the importance of any program of home health care and the attention that must be paid to the appropriateness of the home itself.

Whereas good family relationships are fundamental to propriety, the actual physical accommodations and their proximity to available services should be given equal consideration, whether the housing is under private, quasi-public, or public auspices. Principles of architectural design such as public health agencies propose for health facilities to reduce hazards and to be useful even for those with orthopedic handicaps may be applicable to private housing.

Certainly, in any large multiple dwelling as well as in individual homes accommodations that enable the chronically ill to remain at home have economic and social values that appear to merit serious thought.

The advice and help of health personnel are, or should be, an integral factor in such planning. As we look ahead to more extensive public housing programs for the elderly this becomes self-evident. But most conferences bog down on questions relating to the services and kinds of living quarters that are desirable and functional for the elderly under changing

health circumstances. It is not a question of what, or how much of what, should be included in proposed or future housing plans for adequately accommodating the sick or infirm; we are confronted with the immediate issue of what should be done for those who have lived in housing developments long enough to be now among the aged. The housing and the tenants have aged together.

Community Organization

As we consider the community in which the chronically ill live and realize how great the gap is between facilities, services, and our knowledge about who the chronically ill are and what their demands are, it is easy to become discouraged.

Yet there is a trend (and perhaps the needs of the chronically ill are partially responsible) which is quite encouraging. This is the movement for the gradual merger of health and welfare planning agencies. Citizens are showing greater interest as more and more families are faced with problems for the solution of which neither services nor facilities exist, to say nothing of funds.

In these community movements there is a new realization that no single group in the community can be exempt from participation in both planning and action. Management and labor and professional personnel from all governmental and voluntary agencies and disciplines, including the church, and interested laymen will all be involved since all are directly affected. There is still the troubling tendency to specialize in disease entities or in groups defined by age and other distinctive characteristics, but even in specialized agencies (for example, the heart associations and commissions for the aging and aged) there is an intense awareness of the need for being a part of the local, State, and national communitywide approaches to the prevention and control of chronic illness.

Another encouraging sign is the trend to bring together, at least as affiliates, the various institutional programs of diagnosis, treatment, and restoration that serve the chronically ill. It will be still more encouraging when social service agencies are more definitely coordinated with and are promoting this type of affiliation

A refined method of estimating numbers of future births, based on age-parity specific rates, is used to obtain two series of birth projections for the period 1956-65.

Short Range Birth Projections

JOSEPH SCHACHTER, B.B.A., DEWARD E. WAGGONER, Ph.D., and PASCAL K. WHELPTON, B.A.

ESTIMATES of the number of births that will occur during the next 10 years are of considerable importance for effective program planning in areas of public health, social welfare, economic activity, and community facilities. In response to the need for such data, various methods have been developed for estimating the number of future births on the basis of alternative assumptions as to fertility trends. These estimates are generally called projections. While they do not purport to predict the future, projections are usually designed to provide alternative birth series representing the range of reasonable possibility. A large element of judgment is, of course, involved, but a knowledge of fertility trends and an understanding of the current demographic situation are basic factors in the quality of the results.

Of the various methods for making birth projections, the one most widely accepted uses age-specific birth rates to measure fertility (1, 2). This rate is defined as the number of births to mothers of specified age per 1,000 women in the corresponding age group. Time

series of these fertility rates are extrapolated on the basis of alternative assumptions as to future trends. A parallel series of estimates of the projected female population in the reproductive ages is obtained by "aging" the present population the required number of years and adjusting for anticipated mortality and net immigration. The projected rates are then applied to the projected numbers of women to derive estimated numbers of births.

A logical refinement is introduced into the foregoing procedure by the substitution of the age-parity specific birth rate as the fertility measure. This rate is a birth probability, having as its denominator the number of women of specified age at the beginning of the year who are subject during the year to a birth of specified order. The numerator represents the number of these women who experience a birth of this order during the observation year. Thus the age-parity rate identifies the female population at risk of pregnancy not only in terms of the women's ages but also the order of birth to which they are subject. The age-specific rate, of course, does not take explicit account of this latter variable.

In the proposed method of projection the birth probabilities are extrapolated and applied to successive cohorts of women classified by age and parity. The end product is a series of birth frequencies classified by single years of age of mother and by birth order. We have applied this procedure experimentally to obtain two series of birth projections for the period 1956-65, based on available fertility data

Mr. Schachter and Dr. Waggoner are assistant chief and chief, respectively, of the Natality Analysis Section, National Office of Vital Statistics, Public Health Service. Mr. Whelpton is director, Scripps Foundation for Research in Population Problems, Miami University, Oxford, Ohio. The paper is based on one presented at the meeting of the Population Association of America, Chicago, May 4, 1958.

A series of publications on air pollution, poisoning, and library resources have been issued by the division of occupational health, Texas State Department of Health, in Austin. Their titles are:

Ordinances and Legislation Related to Air Pollution, OH-20, December 1957; Current Trends and Approach to Air Pollution Problems in Texas, OH-20A, January 1958; The Problems and Effects of Air Pollution, OH-20B, January 1958; Communities and Counties in Texas Where Accidents Involving Use and Transportation of Atomic Materials Might Occur, OH-25, April 1958.

Poison Control Centers: Recommended First Aid Measures, OH-24B, June 1958; Poison Control Centers Located in Texas, OH-24A, June 1958; Economic Poisons Currently Recommended by Texas Agricultural Extension Service, and Organisms Against Which Recommended, OH-6-1 (superseding OH-6), March 1958.

Important Economic Poisons, OH-5-1 (superseding OH-5), March 1958; Poison Control Centers: Toxicology Information, OH-24, April 1958; and Occupational Health Library, OH-19-1 (superseding OH-19), April 1958.

Figure 2. Actual and projected numbers of births, United States, 1940-65.

3. Have a slope of zero in 1960.

The following general equation was used to fit the curves to each of the series of observed data:

$$v_x = ax^2 + bx + c.$$

where v_x denotes the computed rate corresponding to the abscissa x (year-1950). Here a , b , and c are constants to be determined for each series in accordance with the conditions previously stated, which lead to the expressions:

$$a = \frac{\sum_{x=0}^5 M_x \left(Y_x - \frac{Y_4 + Y_5}{2} \right)}{\sum_{x=0}^5 M_x^2}$$

$$b = -20a$$

$$c = 69.75a + \frac{Y_4 + Y_5}{2}$$

where Y_x is the observed rate in the year 1950 + x , and $M_x = x^2 - 2x + 69.75$.

Separate equations conforming to the conditions set forth above were computed for each of the series of age-parity rates and mathematically extrapolated to 1960. As a visual check on the goodness of fit, freehand curves were also plotted and extrapolated, and the results were compared with those obtained mathematically. In a few cases the freehand curve appeared to provide a more reasonable basis for projection purposes, and these were so used. But in general, the mathematical results were found to be suitable. Age-parity rates were then derived algebraically for each year 1956 to 1960, and the rates for the latter year were used also for the 1961-65 period.

Cohort Survival

The next step in the projections was the application of the projected rates successively each year to the numbers of women of corres-

through 1955 and on alternative assumptions as to future fertility. All birth data are adjusted for under-registration.

Projection Series A

Age-parity specific birth rates for the period 1950-55 were furnished by Whelpton, together with figures showing the estimated distribution of the female population as of January 1, 1955, by single year of age and by parity. These data and a detailed discussion of their nature will be presented in his forthcoming fertility monograph, which revises and expands an earlier publication on the subject (3). The birth rates were formed into time series for each age-parity group and examined to determine their trends in recent years. There were about 240 such series, some of which are illustrated in figure 1. In general, the trend showed an upward movement during the 6-year period but at a declining rate.

Fertility Assumptions

For extrapolation purposes, various assumptions could, of course, be made as to the future direction of fertility trends. A reasonable possibility, however, was that these curves would level off by 1960 and remain at that level until 1965. This hypothesis formed the basis for series A, the first of two illustrative projections. A second series, series B, was also prepared, based on the assumption that the 1955 age-parity rates would remain the same in each of the years 1956-65 (fig. 2).

To apply systematically the fertility assumptions underlying series A, a second-degree equation was fitted to the 1950-55 age-parity rates, the curve of which would satisfy the following conditions:

1. Form a least-squares fit to the data for 1950-55.
2. Pass through the arithmetic mean of the 1954 and 1955 rates at the ordinate midway between those for the 2 years.

Figure 1. Age-parity rates for third births to women 25-29 years of age, United States, 1950-65.

grants to the total number of births during the projection period is small. For 1960, births to immigrants represent only 1.7 percent of the estimated total, and for 1965 less than 3 percent.

Adjustment of First-Birth Estimates

An analysis of first-birth and marriage figures during the postwar period shows a high linear correlation (.96) between the two variables, with a lag of 1 year. It is believed that, if this relationship is utilized, some further refinement is introduced into the projections of first births for 1956-58. Since annual marriage data are presently available only through 1957, it is not possible to carry out the adjustment of first-birth projections beyond 1958.

The following regression equation for the relationship between marriages (X) in year M and first births (Y) in year $M + 1$ was derived for the period 1948-55:

$$Y = 668,000 + 0.3128X$$

The adjustment of first births by single years of age of mother in the original projections to the estimate of first births based on marriages was made on a pro rata basis. The revised figures differed only slightly from those obtained by the use of parity rates; the amount of ad-

justment averaged about 1 percent per year for the 3 years.

Results

On the basis of series A assumptions, total live births increase from 4,104,000 in 1955 to 4,446,000 in 1960, and then climb more rapidly to reach a figure of 4,994,000 in 1965 (table 1). First births, after an initial rise from 1,138,000 in 1955 to 1,164,000 in 1957, drop off slightly in 1958 and 1959. Thereafter, however, the number climbs steadily to 1,345,000 in 1965.

Second births decline for the first 6 years of the projection period (from 1,104,000 in 1955 to 1,075,000 in 1961), then turn upward during the next 4 years, and by 1965 number 1,150,000. All higher-order births increase consistently during the 10-year span. The following figures show the relative increase of birth-order frequencies from 1955 to 1965 implied by projection series A:

Live birth order	Percent increase
Total-----	21.7
First-----	18.2
Second-----	4.2
Third-----	9.4
Fourth-----	30.7
Fifth-----	55.4
Sixth-----	74.8
Seventh-----	87.5
Eighth and over-----	81.8

An interesting aspect of this birth projection technique is that it permits the derivation of cumulative fertility rates and estimates of the

ponding parity and age. The method used was that of cohort survival. This refers to the shifting of a population at a given date forward in time, making allowances in each age cohort for attrition due to mortality and for adjustments in its parity composition. As each cohort advances from one year to the next, its parity distribution changes to reflect its fertility experience in the previous year. The process involves an iterative series of successively linked computations.

Mortality and Migration

Mortality projections were needed to compute the proportion of each population cohort surviving from one year to the next during the 1956-65 period. The necessary survival factors were furnished by Thomas N. E. Greville, assistant chief actuary, Social Security Admin-

istration. They reflect assumptions of "medium" mortality during the 10-year period, that is, a moderate continuation of the presently declining mortality trends.

Account was taken separately of the number of births to the net immigrant population during the 1956-65 period. Estimates were obtained from the Bureau of the Census of female immigrant population projections by age for the 1957-60 and 1961-65 periods. From these data estimates of annual net immigration were derived. The cohort survival method was used to obtain the age distribution of each year's complement of immigrant females in each of the remaining years of the projection period. To the cumulative totals of immigrant females in each year 1956-65 were then applied the age-specific fertility rates derived for the general population. The contribution of immi-

¹ Based on assumption that rates in 1956-65 will remain at 1955 level.

² Actual.

³ Rates based on Whelpton's population estimates, which differ slightly from those prepared by the Bureau of the Census and used in National Office of Vital Statistics publications.

percent of the official counts (table 4). With regard to birth order, the largest difference in 1956 was 2.7 percent, and the unweighted average difference for all birth orders, ignoring signs, 1.1 percent. The situation was similar with respect to age of mother. The largest difference was 2.8 percent, and the average difference, 1.5 percent. Virtually all the projected birth-order and age-of-mother totals for 1956 correctly reflected the direction of the true change from 1955. National data for 1957 by age of mother and birth order have not yet been tabulated. It is recognized, of course, that 1- or 2-year projections, however made, are much more apt to approximate the actual counts than projections 5 or 10 years ahead.

Projection Series B

A second projection, series B, was computed on the basis of the fertility assumption

that the age-parity birth probabilities during the period 1956-65 would be the same as in 1955. The mortality and migration assumptions are the same as in series A. The results are shown in tables 2, 3, and 5.

Series B births in 1956 and 1957 are below the numbers actually occurring in these years, and present indications are that they will fall short of 1958 experience. Should there be a downturn in fertility during the remaining years of the projection period, however, series B projections may provide a closer approximation of the birth situation during the first half of the 1960 decade than series A. In addition to its usefulness as a "low" series in bracketing possible future natality experience, series B serves two other purposes. It throws light on the question of the extent to which population and parity factors would result in a rise in the number of live births despite a

percentage of women at various ages who are childless. The cumulative fertility rate is the number of births per 1,000 survivors of each cohort. This measure is useful in relation to questions regarding the extent to which family size is increasing. For example, table 2 shows that in 1955, women aged 45-47 years had a cumulative fertility rate of 2,233 births per 1,000. The corresponding age group, according to the fertility assumptions of series A, will have a rate of 2,646 per 1,000 in 1965.

It is recognized, of course, that the foregoing figures represent the extension of current high levels of fertility. These high levels may be due to the fact that relatively more women are marrying, are doing so at a younger age, and are completing their families earlier in life. To the extent, therefore, that the current situation is attributable to these factors, the result may be primarily a change in the timing and spacing of children in relation to the mother's age and the duration of marriage rather than a large increase in the total number of children she will ultimately bear.

Table 3 shows the estimated percentages of

women who were childless at specified ages in 1955 and the corresponding percentages in 1965, based on series A projections. According to these figures, a much smaller proportion of the women surviving to the end of their child-bearing period will be childless in 1965 than is presently the case. In 1955, 23 percent of the women reached the end of their reproductive span without having a live birth. For women reaching age 45 years in 1965, the corresponding proportion would be 14 percent. The latter figure is only partially dependent upon the birth assumptions of series A. The women who will reach ages 45-47 years in 1965 had already experienced such high first-birth rates by 1955, at which time they were aged 35-37, that only 15 percent were still childless. Hence, regardless of their fertility experience during the next 10 years, they will have a substantially lower rate of childlessness in 1965 than the corresponding age group a decade earlier.

It is possible to compare series A projections for 1956 and 1957 with figures now available for these years. Insofar as the totals are concerned, the projected figures are within 0.3

Table 4. Comparison of projected birth figures ¹ for 1956 with final tabulated data for that year

Cockroaches as Vectors

Recent publication of Medical and Veterinary Importance of Cockroaches by Lewis M. Roth and Edwin R. Willis (Smithsonian Publication No. 4299, 1957) has raised the question as to whether the cockroach is being neglected as a vector of infectious disease. It is well that the question is raised, because conventional assumptions in public health work deserve periodic appraisal and challenge. That the authors make no solid case for more energetic suppression of the cockroach as a disease vector does not detract from the utility of their work as a compendium of information that was formerly scattered to the far ends of the library shelves.

Cockroaches are recognized as mechanical transmitters of various pathogens, and because of this and their general obnoxious characteristics they have been and will continue to be the object of individual and community control efforts. The data presented only confirm this situation.

Roth and Willis have outlined the habits, habitats, and dispersal of cockroaches and the association of cockroaches with viruses, bacteria, fungi, protozoa, and helminths. They review bites and allergic responses, accidental invasion of man, cockroaches as human food, cockroaches in medicine and folklore, and diseases incorrectly attributed to cockroaches. They compare the significance of cockroaches and flies. Especially useful is their annotated list of pathogenic organisms and their reported association with cockroaches.

The authors undertake to prove that cockroaches are highly dangerous potential vec-

tors of disease. But the association of cockroaches with pathogens is yet to be adequately evaluated.

Epidemiologists do not consider that reports of the presence of pathogenic organisms on cockroaches is evidence that the species is a natural vector. Neither is survival of the pathogens after experimental inoculation in cockroaches proof that roaches are experimental vectors. Ecologic associations need to be demonstrated to support such a claim.

The work of Marcel Graffar and Simone Mertens (Ann. Inst. Pasteur, Paris, 79: 654-660, 1950) cited by Roth and Willis is the most persuasive study reported. These workers observed that during an epidemic of food poisoning new infections of *Salmonella typhimurium* occurred in spite of quick isolation of patients, the absence of healthy carriers, and the lack of detectable contact except through cockroaches. It was observed that cockroaches overran the nursery at night and *S. typhimurium* was isolated from cockroaches in the vicinity of the infants. The epidemic was checked immediately when the nursery was disinfected with DDT. The epidemiological data cited do not definitely incriminate cockroaches even in this instance.

Structural and ecologic adaptations of cockroaches which are conducive to their potential as disease vectors are widely recognized. One may well speculate as to why they are not more prominent as conveyors of pathogens. New evidence or reinterpretations of present evidence may eventually shed the necessary light.

leveling off of the fertility rate as such, and it is useful in demonstrating the practical differences between projection results based on age-parity rates and those based on age-specific rates.

Comparison of Methods

For the purpose of comparing the two methods of estimating births, another projection, series C, was made for the 1956-65 period. Series C parallels series B in all respects except the method of measuring fertility. In series B, age-parity rates were used; in series C, age-specific rates. In both series, however, fertility was assumed to be the same in each year during the period 1956-65 as in 1955.

Table 6, which presents a comparison of the results of series B and series C projections, shows that there is an initially small but gradually widening gap between the total numbers of births obtained by the two methods, with series B yielding the larger numbers. By 1960, there is a difference of 2.5 percent, and by 1965 this gap widens to 4.8 percent. Differences for the individual age-of-mother groups are even greater. In 1965, for example, the projected number of births to mothers 30-34 years of age is 10 percent greater than the number obtained by the age-specific rate

method. At ages 35-39 years, the difference is 18 percent. It should be emphasized that these differences are a function of the specific assumptions of population composition and fertility in this particular situation. They are not necessarily the maximum differences that could result from the use of the alternative methods.

Conclusion

As stated at the outset, the illustrative projections presented here are not predictions. No effort has been made to prognosticate trends in the social, psychological, and economic variables affecting fertility. The parity-rate method of birth projection, like the age-specific rate method, is essentially a mechanism for translating assumptions of future fertility into numbers of births. The significant difference between the two methods is that the use of parity rates provides a greater degree of fidelity in the resultant translation.

The age-parity rate is, of course, not the ultimate refinement in fertility measurement. If adequate child-spacing and marriage-duration data were available, the additional use of these variables would permit further delineation as to fertility risk status, and probably would improve the stability of the time-series data forming the basis of fertility projections.

to be sanitation aides. In a month's course at the University of Alaska in Fairbanks, given by members of the department, a man from an Eskimo village learns ways of outwitting or using the harsh environment in practicing sanitation.

He learns about germs, as well as why and where dog teams should be tethered, about jetting wells through the permafrost, and how to use oil drums and sod pits in waste disposal. He also masters tools he may never have seen before and practices the techniques of persuading people to adopt the new devices he has learned to make.

When the sanitation aide completes the course and returns to his village, he is equipped with the tools he will need as well as his new knowledge. To a people accustomed to centuries-old ways, the Eskimo sanitation aides bring a chance for better lives. (Photographs were supplied by the Sanitation and Engineering Section, Alaska Department of Health.)

In fieldwork during the course at Fairbanks, aides fasten faucets in water barrels used to collect rain from the roofs in villages when other sources of water are lacking. The men learn to use tools, such as the knock out punch, which some have never seen before.

Teddy Brink of Kasiglook uses a level to check the slope of the barrel stand so that water will flow into the house even under a low head. A pebble tied

to the string hanging from the trough to the top of the barrel serves as an eave spout. Class project was installing rainwater system for this building.

Robert Cleveland, *left*, of Shungnak and Joseph Lomack of Akiachak make a laboratory slide as they learn about germs in the sanitation aides' course. A microscopic view of the bacteria of tuberculosis, a disease familiar to them, is a peek at a new world.

Eskimo Sanitarians

Providing isolated Eskimo villages on the shores of the Arctic Ocean with a safe water supply and adequate waste disposal is a challenge. Year-round permafrost, a frozen water supply, summer flies and mosquitoes, and a people bound by traditions are some of the obstacles to sanitation in such villages. But villagers are overcoming the obstacles with the help of the Sanitation and Engineering Section, Alaska Department of Health.

Under contract to the Alaska Native Health Service of the Public Health Service, the department in 1955 began training men, selected by their village councils,

Instructor Jim Savage, *third right*, shows village presidents, through a microscope, material removed from their teeth. To further the aides' future

projects in their own communities, the presidents of their home villages joined the students for the last week of the 1957 course at the University of Alaska.

The surgeon's personal attention to his patient and careful explanation of surgical procedures reduce apprehensions and aid recovery.

Psychological Preparation for Surgery

CHARLES S. BRANT, Ph.D., HERBERT VOLK, M.D., Med.Sc.D., and BERNARD KUTNER, Ph.D.

NEARLY all practicing surgeons would agree in principle that a total-care approach to the management of patients undergoing surgery should include careful psychological preparation. But such preparation for emotional and social problems resulting from hospitalization, surgery, convalescence, and rehabilitation is not always regarded as essential to comprehensive medicine, even though the literature attests to its importance. Kaufman (1) writing of the patient's need for emotional support, states:

"The patient must be emotionally prepared to accept necessary surgery without undue anxiety and fear. Everything must be directed toward reducing the psychological stress and trauma of anesthesia and surgery to a minimum. The patient must receive the emotional support he needs and deserves during the immediate postoperative periods. . . . A properly utilized half hour or hour of psychological preparation may give the patient sufficient emotional security to obviate preventable psychosomatic complications. Furthermore, it seems to me that such

Dr. Brant is assistant professor of anthropology and sociology, Portland State College, Portland, Oreg., and was formerly research associate in surgery at the Albert Einstein College of Medicine. Dr. Volk is assistant professor of surgery, and Dr. Kutner is assistant professor of preventive and environmental medicine at the Albert Einstein College. Their research was supported by the Russell Sage Foundation and by a grant from the National Institutes of Health, Public Health Service.

briefing reduces the patient's anxieties and fears to such an extent that he takes the anesthesia better and has less postoperative pain and discomfort. . . . And he seems to make speedier recovery from the effects of surgery than the patient who is emotionally unprepared. This is equally true for emotionally normal patients as it is for neurotic patients."

Dyk and Sutherland (2) also stress the surgical patient's need for emotional guidance and rapport with his surgeon. In their study of colostomy patients they found that "anxiety and fear of injury, in some cases mounting to confusion, panic, or despair, were reported by all as reactions to impending surgery."

In another report, concerned with depressive reactions of patients to cancer surgery, Sutherland and Orbach (3), after speaking of anxieties about the nature of the disease, the impending surgery, possible death, or post-surgical social isolation and inacceptability, commented:

"These reactions are particularly prone to occur when the patient is unable to relate to medical personnel. . . . Mistrust is reinforced by the impersonality of clinic and ward procedures and the 'faceless surgeons.' To one depressed patient, surgery represented being cut up by a group of strangers."

Elsewhere, Sutherland (4) wrote: "Apparently prophylaxis is the best treatment. A warm relationship between the patient and the physician is essential. This relationship should permit the doctor to be seen as protective rather than threatening; it should permit easy com-

Sanitation aides rig a tripod for exploratory jetting and drilling for water. Fieldwork was done in the university's geophysical area.

Cutting and threading water pipes are tasks new to them, but Herb Apassingok, left, of Gambell, and Teddy Brink readily master the skill.

Tom Brown, left, of White Mountain and Wilbur Karmun of Deering complete a grate for an incinerator. In an Eskimo village, dog food would be heated on top of the drum while trash was

burned inside. Right. Students prepare training aids they will use to introduce new devices in their home villages. Community education methods are a part of the aides' course.

sample of the resident surgical staff and graduate nurses on the surgical wards, and informal interviews, of varying length and depth, with a sample of interns serving on the surgical service. We also observed interactions between physicians and patients receiving treatment on the wards, during teaching rounds conducted by the attending surgeons and in the recovery room.

Results

Some qualitative findings from the study throw light on the question: What are the inherent problems, difficulties, or obstacles in developing total care for surgical patients in a teaching hospital setting? Other findings from this study have been presented in somewhat different contexts (8,9).

Case 1. A 66-year-old retired, unmarried, white woman came to the hospital because she had noticed 2 weeks earlier two small lumps in one of her breasts. When she noticed the lumps, the patient stated, she believed they were due to nervousness, for which she sought relief. In the clinic, the physician said that the lumps were "something serious" and that she should enter the hospital for treatment. At that point, the patient asked if she couldn't go home and return in 2 days, a request made, she admits, for the purpose of avoiding hospitalization. She was dissuaded from this course and admitted to the inpatient surgical service.

Following admission, the surgical staff decided that the patient should have a biopsy and possibly a radical mastectomy. The intern assigned to the case told the patient it was necessary to remove "a little" of the lumps, that then they would probably "go further" with surgery, perhaps removing the entire breast, although they hoped it could be avoided, and that following this surgery, the patient would receive "some treatments." The patient ventured anxiously, "I hope it's not too serious." The physician replied, "No, no. Now you just smile and don't worry." The patient then signed the consent-for-surgery form and the intern left. The patient stated in the preoperative interview that she was nervous and afraid of surgery and recalled postoperative pain from a hemorrhoidectomy some

years earlier. She added that it was a shock to her to come to the hospital for relief of nervousness and be hospitalized for surgery.

The surgery consisted of a biopsy and simple mastectomy, followed by radiotherapy.

At postoperative interview, the patient stated that going to the operating room she felt frightened and worried about survival, and regretted she didn't tell her friends goodbye, just in case she didn't return. When she awakened from anesthesia, she knew vaguely that she was "somewhere"; she heard only footsteps and it seemed very quiet. Her first feeling was again of being afraid and wondering if her breast was gone. This question went unanswered until the morning of the first postoperative day, when the intern told her only a small portion of the breast was removed and that she would receive "at least two" radiotherapy treatments. The patient thought she still felt a lump, and the intern explained that what she felt were sutures. The patient told us that she wanted to know what caused her trouble and what she would need to do to care for herself at home but felt "too timid" to ask questions of the doctors.

A few days after the operation the patient received her first radiotherapy. Interviewed the following day, she stated that the experience was very frightening: The sight of instruments on a table in the radiotherapy room made her fearful that further surgery was planned, and the radiotherapy equipment itself upon being lowered over her, was fear provoking. Nothing the patient could recall indicated that the radiotherapy procedures had been explained to her.

Here we see manifestly an anxious, elderly lady, in whom ignorance concerning cancer and denial of the illness was operating. Proper psychological management of her case requires a fuller understanding of her emotional responses to the ominous news of possible major breast surgery and even death. Fear of surgery, concern over removal of a breast, and anxiety about one's death are the most common emotions found in patients with breast disease. If they are not dealt with directly, patients go to and return from surgery with unrelieved apprehensions.

Case 2. A 50-year-old white salesman w

munication and discussion of irrational beliefs and misconceptions. . . .

"A good patient-physician relationship, beginning with the initial diagnostic examination, is the patient's best guarantee against the development of crippling beliefs and their expression in unnecessary restriction of activities."

Others have emphasized the surgical patient's need for information and explanation. For example, the widely known standard textbook, Babcock's *Principles and Practice of Surgery* (5), states:

"Perhaps the best preparation for surgery is for the patient to know his surgeon. Many times contact with the surgeon is so limited that countless questions go unanswered, causing the patient great worry. It is necessary for the surgeon to explain the purpose of the surgery. While this may be quite obvious to him, it is not always obvious to the patient. . . . Patients want to know what is to be done and why."

In an essay written in 1928, Cabot (6), referring to the impact of the hospital environment upon the patient, said: "The patient finds himself facing a new and often terrible situation. To enter the hospital is often for him the most momentous event of his life, and he needs all the help that can be given him to understand it."

Although every physician appreciates the importance of a sound physician-patient relationship, and every surgeon knows that his patient is a sentient human being with hopes and fears that affect his attitudes toward treatment, we have found that the interpersonal and communicative aspects of the physician-patient relationship in surgical practice are comparatively too often neglected. Generally, in private surgical practice, the physician is keenly aware of his patient's needs. However, since a substantial number of surgical patients receive care from physicians in surgical residency in government-supported hospitals, gaps may appear between patient needs and surgical practice. In 1954, an estimated 1,657,550 surgical patients were discharged from government-supported hospitals in the United States (7). Presumably, the resident staff treated the vast majority of these patients as well as an un-

determined proportion of some 61½ million surgically discharged patients in non-government-supported hospitals.

Purpose of Study

The teaching hospital is one strategic setting for developing in young physicians a comprehensive approach to medical care centered upon the patient. It is here, as intern and resident, that the young physician may acquire, through intensive instruction and by demonstration, example, and practice many of his most important skills and his basic attitudes about patient care.

In order to examine relationships and attitudes between physician and patient, we undertook an exploratory study of the surgical service of the Bronx Municipal Hospital Center, which is the teaching hospital of the Albert Einstein College of Medicine, Yeshiva University. Most of the patients, house-staff members, and nurses interviewed and observed were on the general surgical service. The study was conducted during the second year of the hospital's existence, a period when the organization of services and activities was formative rather than firmly established. Other relevant background factors were: (a) the medical school with which the hospital is affiliated was also in its second year of existence; students, therefore, had not yet begun serving clinical clerkships; (b) the surgical service was frequently extremely busy, with wards filled to capacity or nearly so; (c) there was an acute shortage and considerable turnover of experienced graduate nurses, practical nurses, and nurse's aides; (d) emergency cases constituted a large percentage of the total work of the surgical service; and (e) the patient population was largely geriatric immigrants of European origin and had language difficulties and environmental handicaps.

Procedures

Before and after operations, we interviewed 50 surgical patients, unselected except for diagnosis. The selected diagnoses were gastrointestinal, genitourinary, gall bladder, peripheral vascular, respiratory, and skin disorders. Formal interviews were held with a

Case 4. A 47-year-old married man was sent to the hospital by his private physician, who had told him that an X-ray showed a shadow on part of one lung and that this might be a tumor. He was given the same diagnosis by staff physicians in the hospital.

The patient's conception of the intended treatment was "an operation on the part of the lung with the shadow." This was to be done the following day.

Asked if he had questioned the staff physicians about his illness or the planned surgery, the patient said: "Oh, yes. The doctors told me they would like me to ask them about anything that was on my mind. I wondered if the tumor in my lung couldn't be cured by radium. They explained that the best way to be sure I would be cured would be to take the tumor out completely. I believe I really felt a little afraid of an operation on my lung since my family doctor wouldn't even do one on the hernia that I've had a long time. I told the doctors here about this, and they explained to me that this was because the lung problem was more urgent. They assured me that all the tests showed my general health was sound and that I could take the lung surgery without any danger." The patient added that he felt very relieved to have had things cleared in his mind through discussion with the staff physicians, because he had been quite upset when he first learned he required lung surgery.

Interviewed after the operation, the patient related that he felt he was getting fine treatment and singled out the staff surgeon's visits and comments about his progress as making him feel better both physically and mentally. His only problem was wanting to get up and around a little sooner than the surgeon wanted him to.

This case demonstrates as clearly as any studied the value of briefing the patient factually about postoperative events: He knew that he would awaken in the recovery room, where special care would be given; that he would be expected to cough, and the reason why; that there would be a drainage tube coming out from the operative area; that he would be on a restricted diet for a time; and that he would begin ambulation about 2 days postoperatively.

Discussion

We introduced the above case studies with a question to which we now return: What are the inherent problems, difficulties, or obstacles in developing total care for surgical patients in a teaching hospital setting? Perhaps the central problem lies in the house officer's definition of his tasks in medical care and the purposes served by the institution. Quite obviously, he is there to learn, and to service hospital patients. Indeed, one may say that his purpose is to learn through serving. In the process of being a physician, he acquires knowledge and skills and extends his experience, which in turn make him a better physician. For the resident, the purpose is to learn to be a surgeon; for the intern, it is to learn more about surgery and care of surgical patients, perhaps as a preliminary to entering surgical residency training, perhaps only as part of general medical training.

The matter becomes somewhat more complex, however, when one goes beyond the obvious functions of the house officer and asks: What, is his conception of his role or task? What does he regard as relevant and significant knowledge to acquire, and what services should he provide? We find, in answer to these questions, that the house officer is more often than not preoccupied with the technical and mechanical aspects of surgery. The desire to communicate with the patient and to develop sound interpersonal relations is regarded as a luxury not expected in nonprivate practice. The ways in which these views are manifested vary from patient to patient and have differing consequences, as the illustrations indicate. In case 4, where the preparation for surgery was exemplary, the patient went to surgery with minimal anxiety and during postoperative convalescence cooperated fully and cheerfully, because he understood what was necessary and required of him.

Recommendations

Planning for the development of an improved program for the total care of surgical patients in teaching hospitals must include standards for house staff practice and means of implementing these standards. Standards of practice should incorporate the following:

a long history of diabetes entered the hospital with circulatory insufficiency in the right leg. He was scheduled for a below-knee amputation and subsequent transfer to the rehabilitation service for reambulation and prosthesis.

Prior to admission, the patient had been treated unsuccessfully for almost 1 year at several hospitals. The interview disclosed that the failure of therapies had led the patient to lose considerable confidence in physicians. While on the operating table under spinal anesthesia at another hospital, the patient had been acutely distressed upon hearing the surgeons dispute improper functioning of their equipment. This caused him to feel he was in the hands of incompetent people.

The patient, accustomed to a very active life, was most anxious to learn how long his treatment and rehabilitation would keep him from returning to work. He felt that the year already consumed was "like a lifetime." Five days after the operation, one physician informed the patient that he would go to the rehabilitation service soon, and in "no time at all" he would be up and on his way home. He was also assured that a modern prosthesis is usually easy to fit and to use.

Unfortunately, the patient developed a wound infection which necessitated continued treatment on the surgical ward. He developed a reactive depression and complained vociferously. The intern assigned to the case was annoyed by the patient's temperment and demands, feeling there was nothing he could do for the patient beyond changing his dressings daily.

When the infection cleared and the patient was transferred to the rehabilitation service, he stated that he felt much better because now he was "getting somewhere."

This case reveals the need to counsel the patient who has been through prolonged and varied therapy without positive result so that he may understand the rationale of the planning and maintain his confidence in the medical profession. It points up the consequence of overoptimistic and unqualified statements about the length of treatment and rehabilitation, and the need to apprise the patient realistically of what lies ahead before he can resume his regular activities. As for a patient with major

rehabilitation facing him, the doctor's role is by no means confined to the immediate medical treatment. The intern, in this particular case, instead of reacting with a sense of personal annoyance to his patient's anxieties, might have devoted some time to psychological support and viewed his patient's tempermental response as an aspect of the patient's anxiety about the future.

Case 3. A 17-year-old high school girl entered the hospital complaining of dysuria. She was scheduled for cystoscopy 2 days later.

When interviewed, the patient was asked to relate what she believed her trouble was and what the doctors were planning to do for her. In an angry mood, she said: "Dr. L. said they are going to do some kind of examination on me, tomorrow, I think. They say there is something wrong with my kidneys, but they didn't say what. I'd like to know why a young person like me should have kidney trouble, but Dr. L. is always rushing around all the time and I don't get a chance to ask him anything. He doesn't talk to you like a patient." When asked what she meant by the last sentence, the patient said that she had been in another hospital where the doctors explained things to her.

On the day of the scheduled cystoscopy, the interviewer learned that it had been cancelled because the patient's parent had not come to the hospital to give consent for the procedure. The patient had learned that the proposed examination was a cystoscopy, and, having previously had this procedure and finding it painful, prevailed upon her parent not to consent. The patient was discharged to be followed in clinic.

It is evident that in addition to being anxious about a painful diagnostic procedure, the patient wanted the physician to tell her the reason for her illness and the procedure that would be followed. The physician-patient relationship was so undeveloped and communication with the patient was so minimal that the patient acted against medical advice and her own interests. The value of forthright, even if brief, explanation of procedures and planning, presented in a manner that will not alarm the patient, cannot be overestimated. An impersonal attitude toward the patient is one of the contributing factors in the failure of patients to follow medical advice.

plex field leave little opportunity for him to become versed in the recognition and management of a patient's psychosocial needs. Such needs are recognized in surgical literature and by experienced practitioners and teachers of surgery, but they are often inadequately met. Standards of practice as well as steps to implement them are outlined, so that ideal surgical practice with respect to these needs may be approximated in the teaching hospital.

Textbook on Medical Care Organization

More than a hundred articles on the organization of medical care are brought together in the recently published textbook entitled "Readings in Medical Care," edited by the Committee on Medical Care Teaching of the Association of Teachers of Preventive Medicine.

The book contains basic studies dating back to the 1920's as well as important recent ones in books, journals, and monographs, together with extensive reading lists. Several articles appeared in *Public Health Reports* and other government publications, and many are the work of Government employees or former employees, printed elsewhere.

Prepared in response to a widely felt and frequently expressed need for teaching material, the new textbook grew out of a conference on preventive medicine in medical schools held in Colorado Springs in November 1952. This conference was sponsored by the Association of Teachers of Preventive Medicine and the Association of American Medical Colleges.

"Subsequent to that searching exploration of the growing importance of preventive medicine in medical education," Dr. George Packer Berry, of Harvard University, says in the foreword, "the Committee . . . have devoted their efforts to understanding, evaluating, and recording changes in the patterns of organization of medical care and health service."

1. In addition to the basic physiological preparation of the patient for surgery, attention should be given to psychological factors. During, immediately after, and at regular intervals following admission to the surgical service, the medical staff alone or in conjunction with nursing and social work personnel should evaluate, by physiological and discursive means, the level of and changes in the patient's anxiety about hospitalization and surgery.

2. Hospital rules and regulations and normal procedures of examining, testing, and caring for vital functions should be explained to the patient upon admission and thereafter as indicated.

3. When the time for surgery has been scheduled, the patient should be informed as promptly as possible. Such information should be withheld until the last possible moment only in those instances in which receipt of such information is felt to be detrimental to the patient's general health.

4. In every instance the nature of the operation and the reasons for its being performed should be explained to the patient in terms he is capable of understanding, without necessarily revealing the diagnosis if this is deemed inadvisable (for example, to remove an "obstruction"; to "relieve pressure"). The patient or his family should not be guaranteed by the house officer the successful outcome of surgery.

5. In every instance the choice and type of anesthetic to be used should be explained to the patient by the anesthesiologist on the day of or evening preceding the operation. Whenever possible, such explanation should be given in emergency cases.

6. Preoperative preparation should include explanation of the physical preparation, transportation to the operating room, nature of the operating room, use of the recovery room (in cases where it is used), and length of time that will elapse before return to the ward.

7. Explanation of postoperative pain and other discomforts should be given the patient in advance of surgery.

8. Before the operation, the patient should be prepared for postoperative parenteral alimentation, drainage tubes, dressings, respira-

tory activity, range of mobility, and time of ambulation.

9. After the operation it is the surgeon's responsibility to discuss the results of surgery, the probable consequences, and the anticipated length of hospitalization and convalescence.

10. The surgeon should discuss the operation and its consequences with the referring physician and responsible members of the patient's family.

The means by which these standards of practice may be implemented are:

1. At the start of the hospital year, the house staff should be oriented through lectures, films, articles, and demonstrations dealing with the total care of surgical patients.

2. At evaluation conferences, house staff members (residents universally and interns where possible) should be given an opportunity to present cases completely worked up from surgical, social, and psychological points of view.

3. Each resident should be given specific instruction and supervision in the psychosocial, presurgical preparation of his patients and in the psychological, postsurgical management of his patients.

4. Teaching rounds should include a psychosocial evaluation of the patient's status and specific coverage of patient responses to the outcome of surgery.

5. Each resident should be instructed and supervised in methods of interviewing the patient and discussing with him and his relatives his problems.

6. Responsible senior surgeons periodically should rate and discuss ratings with residents and interns on the house officer's performance of the psychosocial aspect of his work as well as other aspects.

7. Psychiatrists, social workers, and social scientists should collaborate in these activities designed to improve physician-patient relationships.

Summary

For the surgeon-in-training, the exigencies of a heavy work schedule, large patient load, and necessity of mastering the specialized knowledge and techniques of an increasingly com-

Transfer in San Martín

After 11 years of work by Servicio Cooperativo Interamericano de Salud Pública in San Martín Department, in January 1958 we turned over the health unit to Peru's Ministry of Health. Since 1946 SCISP has gradually developed public health and medical care services for the 400,000 people living in this high, jungle area.

The health unit for San Martín consists of a 50-bed hospital and health center in Tarapoto, a health center in Moyobamba, medical posts in Lamas, Rioja, Juanjui, and Saposoa, and 15 health posts in the smaller towns. In accepting responsibility for the health service, the government of Peru assumed a yearly financial obligation of approximately \$130,000, or 3.5 million soles.

—FREDERICK J. VINTINNER, Sc.D., M.P.H., *chief, Division of Health and Sanitation, U. S. Operations Mission, Peru.*

The Road Back

The small government hospital in Voinjama, district and provincial headquarters of Liberia's Western Province, is the center of a proposed project to combat sleeping sickness. Because the trucks that brought supplies to the hospital often took a week to get there from Monrovia, the capital, and this transportation cost \$350, I decided to investigate the logistics of providing services to Voinjama myself.

I made the 200-mile trip to Voinjama in 2 hours in a light plane, but returning to Monrovia in a 4-wheel drive jeep took far longer. The road back goes through French Guinea so visas and re-entry permits had to be arranged. The first leg of the jeep journey ended at Macenta, 36 miles and 4 hours from Voinjama. We were told we had made excellent time; frequent rains turn the laterite of the roads into mud paste, but our jeep was stuck only once, in front of the French customs station.

On this trip I developed an essential skill, bridge building. The ordinary ones are made of logs placed lengthwise across streams. Frequently the wheels of a truck force the logs apart and the truck tumbles into the stream or its axles are suspended on the logs.

After stopping overnight in Macenta, we left early the next morning for N'Zérékoré, still in French Guinea. On the way we crossed the St. Paul River.

Vehicles are ferried across its 100 yards on a hand-pulled barge, but travelers on foot use the famous "monkey bridge," constructed entirely of long vines twisted together to make two handrails connected by a sling. I stepped gingerly across the swaying span which tightens and dips at each step but ingeniously serves its purpose, except when rotting vines are not replaced.

We reached N'Zérékoré, the second overnight stop, after driving the 61 miles in 7 hours. Next morning we drove to Ganta on the Liberian side of the border and made the final leg of the journey to Monrovia in about 8 hours.

When the new road is completed, getting supplies to Voinjama will not be so difficult, and air service to the town may soon be started by Liberian National Airways.

—JAMES P. WARD, M.D., *chief public health and sanitation division, U. S. Operations Mission, Liberia.*

The Spring

Rurrenabaque, a little town in the jungle uplands of Bolivia, was not far from a clear spring at the base of a cliff which could amply serve 5,000 people. The spring was high enough to feed the town by gravity flow. But the people could scarcely reach the spring on foot and Servicio engineers faced formidable obstacles to bring the water to the town in channels.

No road from La Paz, 150 miles distant, led to Rurrenabaque. Planes ferried in most of the equipment and materials needed to convert the spring into an accessible water supply. The dynamite for blasting came part of the way by truck and then by mule pack and canoe to the remote site.

No machines of any size could be used at the spring itself. Drilling for blasting operations had to be done by hand. The piers, heavy pieces of timber 25 feet long and each weighing more than a ton, had to be carried by men through the tropical forest. A human chain passed along the stones for the foundations of the piers.

After more than a year of such labor by the townspeople, the fresh, clear water of the mountain spring flowed into Rurrenabaque.

—HARALD S. FREDERIKSEN, M.D., *chief, health and sanitation division, U. S. Operations Mission, Bolivia.*

Korean Texts

Nurses in Korea will soon have five Korean texts to aid them. The medical care bureau of the Republic of Korea's Ministry of Health and Social Affairs recently issued Basic Nursing Methods and Nursing Care of Pregnant Women, and the Korean Nurses Association has ready for publication two other texts, Medical Nursing and Nursing Care of Children. The Korean Red Cross is planning to publish Home Nursing, which will be a useful reference for public health nurses, home economics teachers, and other professional workers as well as individual families.

—ALFRED S. LAZARUS, PH.D., acting chief, Health and Sanitation Division, U. S. Operations Mission, Korea.

Pipeline

In one day, 100 villagers of Sapum, Thailand, built a pipeline to bring water to their small community from the nearest source, a hillside spring half a kilometer away. After several outlets were installed in the village, the people decided to build a storage tank at the spring and additional branch lines from the main distribution line to more remote parts of the village.

The people volunteered their labor, and the local health department provided the materials for the distribution system.

—ROBERT L. ZOBEL, M.D., chief, Health Division, U. S. Operations Mission, Thailand.

Male Nurses

When the 17 men who started courses in February 1958 at the School of Nursing, Tubman National Institute of Medical Arts, Monrovia, are graduated, this profession may gain new status in Liberia.

Six men and twelve women are taking the 3-year course in professional nursing, and 11 men and 3 women are in the 2-year course for practical nurses.

The 8 students who will study midwifery for 2 years are women. These candidates for the school were selected from a much larger group by written examinations, given in many of the smaller towns as well as the capital, and personal interviews.

Only five of the students come from Monrovia: most are from much smaller towns and the rural areas. Eight are high school graduates, 13 have attended high school, and 15 completed the eighth grade. Their ages range from 16 to 34 years, with 23 as the average age in the professional nursing and midwifery courses and 22 in the practical nursing course.

The students listed their fathers' occupations on application blanks. Most of their fathers are farmers or fishermen, a few are teachers, and three are tribal chieftains.

—JAMES P. WARD, M.D., chief, Public Health Division, U. S. Operations Mission, Liberia.

Sick Students

Fifty candidates came to take the entrance examinations at Itegue Menen School of Nursing in Asmara, Ethiopia. Of the 26 accepted after examination, it was necessary to treat 12 for trachoma, 14 for amebiasis, 2 for congenital syphilis, and 1 for ascariasis.

—A. C. CURTIS, M.D., chief, Public Health Program, U. S. Operations Mission, Ethiopia.

Occupational Health in Peru

The Peruvian National Association on Occupational Health was formed after Peru's first national seminar in this field was held in January 1958. The medical directors and safety engineers of many industrial and mining companies in Peru as well as private physicians, nurses, and public health workers were among the 94 persons attending.

The seminar participants included faculty members from Harvard University, Marquette University, Peru's National University of Engineers, and San Marcos School of Medicine, the Peruvian and the United States consultants in industrial hygiene, and representatives from Brazil, Colombia, Bolivia, and Venezuela.

—FREDERICK J. VINTINNER, Sc.D., M.P.H., chief, Division of Health and Sanitation, U. S. Operations Mission, Peru.

children were to be transported. Teachers were also helpful here. In rural areas, parents provided transportation for the students; in the villages, school buses were used.

Education

Since approximately 50 students were to be brought into the health center at a particular time and remain there for half a day, the health educator planned dental health classes for them. The students were divided into three groups, each designated by colored molars pinned to dresses and jackets, and while some students were passing through dental offices for X-rays and examinations, others were being rotated through classes on dental health, nutrition, and sanitation.

Following is a brief summary of the material presented in those classes:

- **Dental Health.** The objective of this class was to increase the students' interest in the proper care of their teeth. Class instruction included a review of the anatomy and general structure of teeth and emphasized the importance of having and maintaining good teeth. Theories and causes of dental caries were discussed along with the means by which tooth

decay may be prevented and controlled. Proper toothbrushing, selective diet, fluoridated water or topical application of fluorides, plus the most important factor, regular dental visits, were stressed as the principal factors in good dental health.

- **Nutrition.** The objective was to develop a favorable attitude toward a nutritionally balanced diet and an understanding of the kind and quantity of foods necessary for dental health. The nutritionist demonstrated with prepared meals the seven basic food groups (see illustrations) and pointed up the value of a good breakfast. Students were taught to select as afternoon snacks such foods as fresh fruits, fruit juices, carrot sticks, celery, and milk that leave the mouth quickly and are less cariogenic than sweets, which are normally eaten.

- **Sanitation.** Sanitarians showed tests of contaminated water supplies and explained how such supplies become contaminated. The importance of pasteurizing milk was presented. Other sanitation services that were described included restaurant inspection, nuisance abatement, mosquito control, and laws pertaining to offensive trades, such as the operation of slaughter houses.

The health educator used this dental display in summarizing proper toothbrushing, selective diet, fluoridated water or topical application of fluorides, and regular dental visits as the principal factors in good dental health.

A 20 percent reduction in the incidence of caries was obtained from one application of an 8 percent stannous fluoride solution.

Stannous Fluoride Clinical Study in Olmsted County, Minnesota

WILLIAM A. JORDAN, D.D.S., M.P.H., JOHN R. SNYDER, D.D.S., and VIKTOR WILSON, M.D., M.P.H.

RESEARCHERS have shown that stannous fluoride applied topically reduces dental caries (1, 2), and some of their studies have demonstrated that an 8 percent solution of stannous fluoride is superior to a 2 percent solution of sodium fluoride (3).

To provide further information on the value of stannous fluoride as a caries inhibitor, we selected all 7th and 8th grade students in the rural and village schools of Olmsted County, Minn., for our study. This group was the most accessible and also had the greatest number of permanent teeth. Of those eligible, 510 (95 percent), between the ages of 12 and 13, signed up for the study with permission from their parents or guardians.

The Rochester-Olmsted County Public Health Center was chosen as the examining and experimental site because the personnel in its health unit were interested and because its facilities were available. The study was planned to cover 2 years.

Cooperation was then obtained from groups involved or interested in the study: the Roches-

ter Board of Public Health and Welfare, the Olmsted County Board of Health, the Rochester Dental Society, rural and village school officials (including the county superintendent), parents (through the PTA), and teachers (at a teachers' institute). The teachers, who interpreted the facts of the study to students and parents, were indoctrinated at the institute, in an article in their newsletter, and by means of radio, television, and news releases. The county's public health nurses also aided in this respect. All contacts were made during the summer months before schools opened.

Planning Committee

A planning committee composed of a health officer and the health educator of the Rochester-Olmsted County Health Unit, the staff of the Minnesota Department of Health Section on Dental Health, and public health nurses outlined a schedule of 50 examinations per half day. The scheduling was based on a school day which consists of 6 hours. This allowed approximately 3.6 minutes for each dental examination and the same time for the four X-rays taken by another public health dentist.

Since the students came from rural and village schools outside the city of Rochester, arrangements were made to transport them to the health center at specified times. Public health nurses informed all rural and village schools of the timetable and the means by which the

Dr. Jordan is chief, and Dr. Snyder is assistant chief, section of dental health, Minnesota Department of Health. Dr. Wilson is health officer for the Rochester-Olmsted County Health Unit. This study was sponsored by the section of dental health and the health unit and aided by a grant from the Public Health Service.

Table 1. Incidence of caries after a single application of 8 percent stannous fluoride solution to erupted permanent teeth of children 12-13 years of age, at the end of 1 year

Location of new caries	Control group (N=238) ¹	Experimental group (N=234)	Difference between groups	Reduction in percent	P
Teeth.....	2.15 ± 0.112	1.72 ± 0.108	0.43	20.0	0.0052
Surfaces.....	4.79 ± 0.229	4.10 ± 0.221	.69	14.41	.0308

¹ Some teeth thought to be carious when first examined were subsequently found to be noncarious. The incidence of reversed diagnosis was 0.265 for the control group and 0.360 for the experimental group.

faces, as compared with means of 9.560 DMF teeth and 16.240 DMF surfaces for the experimental group. The two groups were practically identical with regard to DMF teeth and surfaces.

Following the initial examination the students were rescheduled for treatment at the rate of 12 to 14 per day, and the information was sent to their schools. Conscientious cooperation of parents in the rural areas helped keep the schedules running as planned. Cancellations or changes in time by individual students were practically nil.

The treatment began with prophylaxis by the hygienist. The teeth in one half of the mouth, upper and lower quadrant, were isolated by cotton rolls, with holders used to keep the rolls in place. A continuous roll was used on the buccal side for the upper and lower teeth. The teeth were then dried by compressed air.

During this procedure the assistant prepared a fresh solution of 8 percent stannous fluoride by dissolving 0.8 gm. of stannous fluoride in 10 cc. of distilled water.

The solution was applied to the clean, dry teeth by a cotton swab, and the teeth were kept wet for 4 minutes. A timer was used to assure uniform applications. The other half of the

mouth was then treated in the same manner. It requires approximately 30 minutes to give a good prophylaxis and a complete topical application of stannous fluoride.

The control group received prophylaxis followed by a water treatment under the same procedure as the treated group.

(An agreement was made with the parent and students of the study that if the study produced favorable results all the students in the control group would receive treatment at the end of the study if they desired.)

Followup Examination and Findings

At the end of the first year, the same public health dentist conducted a followup examination in the same manner as the original examination. Nearly as much time was devoted to planning schedules and appointments for the series as for the original series. A followup session devoted to dental health education was also planned to evaluate the first education program.

Of the 510 students originally examined, 4 were reexamined, 238 in the control group and 234 in the experimental group. As table shows, 20 percent fewer new dental caries were

Table 2. Comparison of caries in surfaces of teeth of experimental and control groups following single application of 8 percent stannous fluoride solution to erupted permanent teeth of children 12-13 years of age at the end of 1 year

Surface	Control group (N=238)	Experimental group (N=234)	Difference	Differences in percent	P
Proximal.....	2.96 ± 0.169	2.35 ± 0.143	0.61	20.60	0.00
Occlusal.....	1.24 ± 0.097	0.98 ± 0.088	.26	20.96	.00
Buccolingual.....	0.59 ± 0.054	0.77 ± 0.082	-.18	-30.50	.00

Practical help in setting up eating patterns for a day was given students participating in the Olmsted County, Minn., stannous fluoride study.

Following an evaluation and summation of the three sessions, a dental health film, *The Gateway to Health*, was shown and discussed. The dental director briefly explained the future plans of the study and what was expected of each student.

In an effort to obviate the use of any fluoridated toothpaste by members of the control and experimental groups, a nonfluoride dentifrice was distributed among them before they returned to their schools. The students were able to obtain additional supplies from the county's public health nurses when the nurses visited the schools, or by coming directly to the health center. Records were kept on the distribution of the toothpaste.

Procedures

The students were assigned in groups of 50 per half day for examinations and X-rays. All received a complete mouth mirror and explorer examination from Dr. William A. Jordan, who used a Burton lamp to illumine mouths adequately. Two posterior bitewing X-rays and one upper and one lower X-ray of the anterior teeth were taken by another public health dentist.

In order to start this study on relatively even terms, the students were divided into two groups comparable in caries experience. The control group had a mean of 9.582 decayed, missing, or filled (DMF) teeth and a mean of 16.373 decayed, missing, or filled (DMF) sur-

Status of **TUBERCULOSIS**

CONFERENCE REPORT

Tuberculosis, still one of this country's most costly infectious diseases, engaged the attention of 3,000 physicians, public health workers, and nurses at the 1958 annual meetings of the National Tuberculosis Association and its medical section, the American Trudeau Society, and of the National Conference of Tuberculosis Workers. The meetings were held concurrently May 19-22 in Philadelphia.

Although tuberculosis was the focal point of the meetings, nontuberculous diseases of the lung and cardiovascular diseases also were discussed, reflecting the broadening interests of the groups. Following a brief summary of tuberculosis facts and figures compiled by the National Tuberculosis Association, highlights of selected scientific papers are presented.

Tuberculosis Facts and Figures

★ Approximately 800,000 people in the United States have tuberculosis, either active or inactive, but in need of medical supervision.

★ Between 50 and 55 million people are infected with the tubercle bacillus.

★ Approximately 90,000 new cases are reported each year, almost 70,000 of which are active cases.

★ The disease causes about 14,000 deaths a year.

★ Tuberculosis costs the United States approximately \$725 million a year, according to a study by the Public Health Service based on 1956 figures.

★ Three principal drugs used in treating tuberculosis are, in the order of discovery, strep-

found in the experimental group than in the control group. The probability of .0052 indicates 20 percent is statistically significant. Surfaces of teeth in the experimental group were 14.1 percent less carious than in the control group.

Table 2 shows the difference in the incidence of caries between the two groups with regard to specific DMF surfaces. The proximal surfaces of the treated group were 20.6 percent less carious than the same surfaces of the untreated group. This is statistically significant. The occlusal surfaces in the treated group showed a 20.96 percent reduction as compared with the control group. The probability of .0478 is just barely significant.

There was a reverse result, inexplicable at present, in the buccolingual surfaces where 30 percent more caries were found in the experimental group than in the control group. The analysis at the end of the second year may shed some light on this situation.

In conjunction with the educational feature of the study at the followup examination, the children were given an evaluation checklist on the subject matter presented the previous year. The children, from five different schools, answered between 70 and 75 percent of the questions correctly. Since there was no original evaluation of the education on dental health, nutrition, and sanitation, no comparisons could be made.

Summary and Conclusion

An 8 percent stannous fluoride solution, applied once to erupted permanent teeth, was

tested in students aged 12 and 13 years in Olmsted County, Minn., to determine the solution's ability to inhibit caries for 1 year. The 510 students were divided into almost identical control and experimental groups. At the end of 1 year, 472 students returned for examination. Compared with the control group, the experimental group had 20 percent fewer carious new teeth and 14.5 percent fewer new carious surfaces. Proximal and occlusal surfaces benefited from the treatment.

A second application of the solution was made at the end of the first year and its effects will be studied this year.

The students were briefly schooled in dental health, nutrition, and sanitation simultaneously with the examinations at the Rochester-Olmsted County Public Health Center. One year later the children were able to answer correctly between 70 and 75 percent of the questions put to them on the subject matter taught.

Research Fellowships in Clinical Nutrition

Ten fellowships for research in clinical nutrition are being offered to medical students by the Nutrition Foundation, Inc., in cooperation with the Council on Foods and Nutrition of the American Medical Association. The fellowships are designed to stimulate a more active interest in the science of nutrition among staff members and students of schools of medicine.

Each fellowship provides \$200 monthly for the student for not more than 3 months of the nonacademic year. Grants will be awarded on the recommendation of a senior investigator, who should make written application to the Council on Foods and Nutrition, American Medical Association, 535 North Dearborn Street, Chicago 10, Ill., by December 15, 1958.

Eternal Verities

- The tubercle bacillus is still the cause of tuberculosis. The primary attack must be here and not diverted too much to secondary factors.

- The disease is still communicable from man to man and from animal to man.

- The tuberculin test is still the best means of locating tuberculous infection whether in the individual or the community.

- Tuberculosis still occurs essentially as a family epidemic, and epidemiology must start with the family unit.

- Tuberculosis is still an insidious and chronic disease; its early stages are asymptomatic. Vigilance is still necessary to detect the disease in its earliest stages.

- In spite of shortened periods of hospitalization, the disease still represents an economic drain in money and time.

- The disease is still socially disrupting in its effects on the family, on employment, and so on.

- Everybody is vulnerable regardless of age, sex, race, or social stratum.

—HERMAN KLEINMAN, M.D., *from a paper delivered at the annual meeting of the National Tuberculosis Association, Philadelphia, Pa., May 19-22, 1958.*

production, which may occur as a result of a variety of stresses or strains, can be highly significant. Maintenance of a proper balance of cortisone would be the objective, Long indicated.

Possibly affecting hormonal balance but perhaps operating in some other fashion, mental attitudes have been described many times as favoring or controlling the progress of tuberculosis, Long said. To some they seem to be as vital as the use or non-use of chemotherapy.

The attitudes Long mentioned included anxiety, complacency, willpower, determination, cooperativeness, hostility, care, and carelessness.

Other factors that seem to influence resistance to tuberculosis are nutrition, other diseases and even accidents, and biochemistry, according to Long.

Dr. Max B. Lurie, of the Henry Phipps Institute, emphasized the influence of the thyroid

on resistance to tuberculosis. He reported that thyroid hormones markedly suppress activity of tuberculosis in rabbits, while propylthiouracil (a thyroid depressant) and removal of the thyroid gland have the opposite effect.

Lurie also reported that production of antibodies against a nonspecific antigen (bovine serum albumin) can be "markedly enhanced" by a thyroid hormone in some rabbits.

Protective Measures

Clean air is the best safeguard against the spread of tuberculosis, advised Dr. Richard L. Riley, associate professor of environmental medicine, Johns Hopkins University, Baltimore.

Riley suggested specifically, in order of decreasing importance, "air purification by ultraviolet irradiation, ventilation with plenty of fresh air, avoidance of crowding, covering coughs and sneezes, spitting into a handkerchief, and use of masks" as protective measures in hospitals.

People catch infectious diseases when infectious material becomes implanted on types of tissue on which it can grow, not simply by touching the material, he explained. Lung tissue is extremely susceptible to the tubercle bacillus; the skin, the upper respiratory tract, and the alimentary tract are much less so.

Hence, it is the small droplets, so tiny that they can be seen only in photography taken with special illumination, that are the culprits, according to Riley. These droplets, produced in large numbers by coughing, sneezing, spitting, laughing, and talking, evaporate in a fraction of a second, leaving dried residues called droplet nuclei. The droplet nuclei are small enough to float about on air currents and can be inhaled deep into the lungs where they are deposited.

Animal studies that have shown promising results with a tuberculosis vaccine were reported by Dr. H. Stuart Willis, of Chapel Hill, N. C. He said that a vaccine made from an attenuated strain of tubercle bacilli known as R₁R_v had offered more protection to guinea pigs than BCG vaccine. Co-authors of the paper were H. M. Vandivere and Margaret R. Vandivere, also of Chapel Hill.

tomyacin, para-aminosalicylic acid (PAS), and isoniazid. Usually two of the drugs are given the patient, but in some cases isoniazid is given alone.

★ Because none of these drugs kills all the tubercle bacilli, because of the phenomenon of drug resistance, and because some patients do not respond to treatment with these three drugs, one of the great needs in tuberculosis therapy is for improved medication.

★ Among the drugs of limited usefulness are pyrazinamide, viomycin, and cycloserine. A new drug is kanamycin.

★ The use of drugs to keep infection under control and the development of new surgical techniques have made it safer to remove diseased areas of the lung which might become foci of new infections.

★ Drugs have also been the key factor in the current trend of treating tuberculosis in medical centers rather than in remote sanatoriums. Since drugs bring infection under control at an earlier date than was formerly possible, the danger of spread of disease by patients under treatment has been lessened. The danger of spread of disease by the unknown, untreated case is as great as ever. Tuberculosis is spread primarily by patients with active disease who cough up tubercle bacilli.

★ The tuberculin skin test and the chest X-ray are the principal instruments for finding tuberculosis. The tuberculin test does not reveal active disease, but it does reveal infection by tubercle bacilli. It is a sensitive index of the danger spots in the community.

★ If a person reacts to a tuberculin test, a chest X-ray is advocated. The chest X-ray is also indispensable to the physician in following the course of the disease, and it may also be used as the primary casefinding technique in many circumstances among adult population groups.

★ A serologic test which may prove valuable in the diagnosis of active disease has recently been developed by scientists at Northwestern University School of Medicine, and is now under extensive study.

★ BCG vaccination for certain groups of the population who are more than normally exposed to tuberculosis is advocated by the American Trudeau Society. It is given only to

persons who are tuberculin negative. Thus the persons in greatest need of protection—the tuberculin positive, among whom most of the tuberculosis occurs today—are ineligible for vaccination with BCG.

★ Studies are underway to determine the possible value of isoniazid as a prophylaxis.

★ A vaccine which could be given to the entire population and which would not destroy the value of the tuberculin test (as does BCG) is among the great needs in the tuberculosis eradication program. Among the other questions for research are how tuberculosis drugs work, how the function of the lung can be preserved despite disease, and a better understanding of the tubercle bacillus itself.

Natural Resistance and Therapy

The popular belief of Hippocrates' day that tall, fair men are more susceptible to tuberculosis than short, dark men may not be so wrong as modern-day scoffers would have us believe, according to Dr. Esmund R. Long of Pedlar Mills, Va., in the Amberson Lecture. Dr. Long is emeritus professor of pathology, University of Pennsylvania, and was formerly director of medical research for the National Tuberculosis Association and director of the Henry Phipps Institute.

Discussing the supporting structure of immunity in the therapy of tuberculosis, Long pointed out that recent studies on military personnel appear to bear out the ancient concept.

"The unexpressed thought seems to be that the characteristics named are genetically linked with other factors that are truly pertinent to native resistance," he said. Among these factors are hormones.

It has long been recognized, Long observed, that people with insulin deficiency have low resistance to tuberculosis, while those with an excess of thyroid hormone are not prone to the development of the disease.

As for the steroid hormones of the adrenal glands, cortisone, in suppressing inflammation, may be beneficial in some forms of tuberculosis, particularly meningitis, and detrimental in others. The important point, Long explained, is that cortisone does modify resistance; therefore, physiological differences in the body's

operated upon either before they became pregnant or during their pregnancy. The operations included removal of a lobe of the lung, removal of a segment of a lobe, and collapse of the lung by a thoracoplasty.

In all instances antimicrobial drugs were given the mother without harm to the child, said Schaefer, but in no instance was the mother permitted to nurse her baby.

Chicago surgeons T. W. Shields, W. M. Lees, and R. T. Fox reported a followup study of 101 persons who had had a lung removed between 1951 and 1955 because of tuberculosis. They found that 11 of the patients died within 60 days of the operation and another 5 died within a year as the result of complications. Nonfatal complications occurred in 18 patients. The majority of the patients, 57, had uneventful postoperative courses.

For patients who have difficulty in breathing because of chronic lung disease, a "window" that will open and close can be carved in the windpipe. Construction and operation of the window were described by Dr. Edward Ernest Rockey, clinical instructor in surgery, New York Medical College, New York City.

The window is cut in the front wall of the trachea and can be reached from the outside through a skin tunnel. The tunnel is entered between two doorlike skin valves located over the front of the neck.

The procedure, used mainly on patients with emphysema, permits access to the tracheobronchial tree so that secretions can be aspirated and medication applied by the patients, according to Rockey. Of the 6 on whom it has been tried, 2 have improved sufficiently to leave the hospital for the first time in years.

Co-authors of the report were Dr. Samuel A. Thompson, New York Medical College; Dr. Charles F. Blazsik, St. Anthony's Hospital, Woodhaven, N. Y.; Dr. Edgar Mayer, New York University Postgraduate Medical Center; and Dr. Israel Rappaport, Columbia University College of Physicians and Surgeons.

Mimics of Tuberculosis

A disease caused by "atypical" mycobacteria that mimic the tubercle bacillus but are distinct from it has been reported among 100 pa-

tients in Florida hospitals. The disease in these patients was discussed by Dr. Albert G. Lewis, Jr., Frank P. Dunbar, Dr. Eunice M. Lasche, and Dr. Ernest N. Lerner, of Tampa; Dr. Robert J. Davies, of Tallahassee; and Dr. Dwight J. Wharton and Dr. James O. Bond, of Jacksonville.

All the patients had chronic pulmonary disease, but the organisms recovered from their sputum had characteristics different from the tubercle bacillus. The bacilli were grouped as photochromogens (yellowish when exposed to light); nonphotochromogens (without color); scotochromogens (yellowish in the dark); and unclassified.

Most of the atypical organisms were resistant to isoniazid and PAS and were partially resistant to streptomycin, according to the Florida report. Treatment was highly effective in patients from whom photochromogens and scotochromogens were recovered, but not so effective among those infected with nonphotochromogens.

"Clinically, radiologically, and pathologically," the report stated, "the cases are indistinguishable from tuberculosis."

Sarcoidosis, another mimic of tuberculosis, was the subject of a symposium. A mimic also of cancer, this lung disease is of unknown origin. The highest prevalence, according to Dr. John S. Chapman, professor of medicine, Southwestern Medical School, University of Texas, is in the southeast. Also, it is found more frequently among Negroes than among whites and is rare in the Chinese and in American Indians, he stated.

Although the steroids—prednisone and prednisolone—do not cure sarcoidosis, they have a suppressive action that may be beneficial "in selected instances where the unremitting course of the disease is producing loss of organ function or is even life threatening," stated Dr. Louis E. Siltzbach, Dr. Mark M. Imberman, and Dr. Howard Grossman, of Mount Sinai Hospital, New York City.

Other Chest Diseases

A negative association between physical activity and coronary artery disease at a young age was suggested in a report by Dr. David M.

Animal experiments have also indicated that a limited degree of immunity to tuberculosis can be transferred by cells from vaccinated animals. These experiments were discussed by Dr. Emanuel Suter, University of Florida College of Medicine.

When monocyte cells from immunized animals were infected with tubercle bacilli, the multiplication of the organisms within the cells was restricted, Suter said, and, furthermore, protection was given mice injected with cells from immunized animals.

These results, Suter declared, show that washed cells from vaccinated animals can induce a limited degree of infection immunity. The limited protection suggests that a complex mechanism is responsible for acquired resistance in tuberculosis. Experiments by others using serum from vaccinated animals point in the same direction, he added.

Drug Therapy and Hospitalization

Development of resistance to kanamycin was reported by Dr. Kenneth Wright, Onondaga Sanatorium, and Dr. Attilio Renzetti, Joseph Lunn, and Dr. Paul Bunn, department of medicine, State University of New York, Syracuse. This drug, made from a mold akin to that from which streptomycin and neomycin are derived, was discovered in Japan by Dr. Hamao Umezawa of Tokyo University.

Reporting on use of the drug with 12 patients who had not improved under other drug therapy, Wright said that by the end of 90 days the tubercle bacilli of all patients had become resistant to the drug, although there was X-ray and symptomatic evidence of improvement in 4 patients. The resistance, he added, was about the same as that observed with streptomycin when this drug was used alone.

Whether the use of another drug with kanamycin will delay development of resistance has not been determined, Wright said. He believes that further study with the drug is indicated.

A combination of cycloserine and viomycin may prove beneficial to patients who do not respond to isoniazid, streptomycin, and PAS, according to Dr. William S. Schwartz and Dr. Ralph E. Moyer, of the Veterans Administration Hospital, Oteen, N. C. Experience with

57 patients with moderately or far advanced disease who had failed to respond to other drugs indicates that the regimen may be the most promising "secondary regimen" so far tried.

A simple method of keeping track of how the individual patient is responding to isoniazid was described by Capt. Robert L. Taylor, Fitzsimons Army Hospital, Denver. Such a procedure is needed because patients vary in the way they metabolize the drug. Some break it down chemically and others excrete it without change. The latter derive the greater benefit.

For the rapid metabolizers, it may be practical to give larger doses than usual, Taylor said. After the patient's use of the drug is determined by a bioassay technique, the blood levels of isoniazid in the patient as the dosage is increased can be determined by simple chemical analysis, according to Taylor.

Despite the wonders of antibiotic and chemical therapy, "treatment of new cases of tuberculosis is best begun in the hospital," asserted Dr. Frances S. Lausdown, Dr. Julia Jones, and Fannie Behlen, of Bellevue Hospital, New York City. Their conclusion was based on a survey of more than 600 patients who had received care through the outpatient clinic of Bellevue, most beginning treatment in the hospital.

Initial treatment in the hospital facilitates complete clinical evaluation, allows careful observation during early periods of therapy when drug reactions most frequently occur, and minimizes the dangers of infection of associates in the home, they said.

Concerning the danger of infecting others, it was found that 42 patients discharged tubercle bacilli longer than 4 weeks, while the rest either had positive sputum for only a brief period or were sputum negative throughout the course of treatment outside the hospital.

Surgical Treatment

Major surgery for tuberculosis, even removal of an entire lung, does not prevent safe childbirth, according to an obstetrician, Dr. George Schaefer, of Cornell University Medical College. He reported on the safe delivery of 32 babies to 29 tuberculosis patients who had been

Health Departments and Prevention of Motor Vehicle Accidents

ALBERT P. ISKRANT, M.A.

THE MOTOR VEHICLE is the chief cause of accidental death in every age group from 1 to 65 years and outranks any other cause of death in the age group 5 to 30.

Motor vehicle accidents annually kill approximately 40,000 persons, injure approximately 5 million, and cause the loss of 100 million man-days. These accidents injure 1 out of every 10 males between the ages of 15 and 24 and cause 40 percent of all deaths of males in that age group. In the group aged 15-24 years, the proportion of motor vehicle deaths in relation to all deaths has risen phenomenally. Pronounced but less drastic increases are seen in the groups 5-14 and 25-34 years old (fig. 1).

The pattern of nonfatal injuries caused by motor vehicles is similar to the pattern of deaths, being highest in the age group 15-24 years. The estimated number of nonfatal injuries in the United States for the period July-December 1957 is shown in table 1, and the estimated annual injury rate for motor vehicle accidents, in table 2.

On the basis of the mortality and injury data available, motor vehicle accidents would certainly appear to qualify as a public health problem, which it is believed is amenable to the epidemiological approach used in other public health problems. Because of their knowledge of epidemiological procedures and

other programs health departments can contribute to the solution of this health problem in a number of ways.

Epidemiological Approach

The epidemiological approach consists of finding out the who, how, where, and when of accidental injuries and deaths, and, if possible, the why. It includes five steps: collection and analysis of data, examination of apparent relationships, establishment and testing of hypotheses, development and testing of control measures, and incorporation of tested measures into prevention programs.

At present there is not to my knowledge any full-scale epidemiological study of motor vehicle accidents being carried out in the United States. One is planned by the traffic institute of Northwestern University, using an interdisciplinary team consisting of a physician, an engineer, and a social scientist, and an epidemiological study of the automobile accidents of adolescent drivers is planned for joint execution by the Harvard Medical School and the Harvard School of Public Health. Several completed studies have been referred to as epidemiological, but these are concerned solely with the host or with human factors.

Host and Human Factors

As with most of the diseases, the mortality rate for motor vehicle accidents is higher for males than for females. The chief toll is among young males in the prime of life, although one-fifth of the deaths from motor vehicle accidents

Mr. Iskrant is chief, Operational Research, Accident Prevention Program, Division of Special Health Services, Public Health Service. This paper was presented at the 24th New England Health Institute, University of Connecticut, Storrs, June 20, 1958.

Spain, a pathologist at Beth-El Hospital, Brooklyn, and Dr. Victoria A. Bradess, medical examiner of Westchester County, N. Y.

The apparent reason is that "activity promotes the development of collateral circulation," they indicated. In other words, the blood vessels of the active man are in a condition, because of exercise, to take over a major role in the circulatory system.

The report was based on a postmortem study of 1,500 sudden deaths in Westchester County during an 8-year period. Deaths from coronary occlusion were classified according to occupation, regardless of economic status. The data, Spain and Bradess specified, showed that the men in sedentary positions had died at a younger age than the men who led a more active life.

To determine whether this might mean that there had been an increase in coronary artery disease or that more inactive than active people had atherosclerosis and thrombosis, they analyzed data on the amount of atherosclerosis among men of comparable age groups who had died suddenly from accidents. They found no significant difference in the amount of coronary atherosclerosis in the various age groups in relation to differences in occupational physical activity.

In another paper, pathologists from several cities reported a new lung disease. Characterized by a stoppage of the alveoli with a protein-like material rich in fats, the disease has been tentatively designated "alveolar proteinosis," according to Dr. Samuel H. Rosen, of the Veterans Administration, assigned to the Armed Forces Institute of Pathology, Washington, D. C.

Co-authors were Dr. Benjamin Castleman, of Massachusetts General Hospital, Boston; Dr. Averill A. Liebow, of Yale University Medical School; Dr. Frank M. Enzinger, also of the Armed Forces Institute of Pathology; and Dr. Richard Thomas N. Hunt, of Massachusetts General Hospital.

Diagnosis was based on biopsy material or autopsy specimens from 25 patients from all sections of this country and (one each) from

Canada, England, and Italy. Although the first case was observed at Massachusetts General Hospital 5 years ago, Rosen said that most of the cases have been seen within the past 3 years.

There have been 8 deaths. In 3 of the patients who died, a fungus disease was superimposed on the original condition, Rosen said.

At the onset of illness, there are in some instances symptoms usually associated with pneumonia. The most common complaint is shortness of breath, usually with cough, he added.

No micro-organism has been detected that can be considered the causative agent. It is assumed that the disease is due to inhalation of a foreign substance, but the only clue, according to Rosen, is that 4 of the patients worked in lumber yards and 2 were electricians.

Treatment with antibiotics or corticosteroids does not appear to alter the course of the disease, and since the disease spreads through both lungs, surgery is not possible, said Rosen.

Lung Cancer

A method of producing cancer of the lung in animals in order to study suspected carcinogens was reported by Dr. Marvin Kuschner, director of pathology, Bellevue Hospital, New York City.

Pellets containing known carcinogens were implanted in the bronchi of rats through an opening made in the windpipe. Following implantation, Kuschner said, squamous cell tumors, the type usually found in cancer of the lung, originated in the bronchus around the pellet and extended into the neighboring lung.

Chemicals used in experiments so far have included, he said, polycyclic hydrocarbons, methylcholanthrene, dibenzanthracene, and benzpyrene. Studies are now underway to determine if lung cancer can be produced by this technique with components of tobacco tar, compounds of chromium, and ionizing radiation.

Co-authors of the paper were Dr. Sidney Laskin and Dr. Norton Nelson, department of industrial medicine, New York University.

have found that immaturity, lack of hostility restraint, lack of stability, absence of tension tolerance control, and aggressiveness are some of the personality characteristics associated with an excessive number of accidents.

Several studies are currently in progress to develop "scales" for measuring these personality traits. It is hoped that the knowledge gained can be incorporated into driver education and other safety programs. The health department can make a definite contribution to the prevention of motor vehicle accidents by promoting and assisting with driver education courses and driver improvement clinics and by helping to translate the results of research into practical education programs.

Studies are being planned and carried out on methods of changing or modifying behavior through the group approach, and otherwise. Corollary studies are needed on the relationship between attitudes and knowledge of safety laws and measures and between attitudes and behavior. Of particular importance in this regard are the studies on the attitudes and behavior of elderly people and on methods of modifying them, since elderly pedestrians have a very high death rate.

Physical and Sensory Defects

It apparently is generally agreed that organic disease, impaired functions, and aging processes increase the accident potential of persons, but the effect of these conditions on actual accident occurrence is, at present, speculative. The extent to which these persons "compensate" for their deficiencies is not known, and differences in "exposure" make comparisons difficult. One

of the problems in the study of accident causation is to select groups which are exposed to constant risk and to observe them long enough to obtain meaningful data.

Employers of persons who will be exposed to high risk of accident can accept presumptive evidence of physical impairments in making their decisions concerning the hiring of applicants. Therefore, employers may accept a list of conditions which would be bars to employment as drivers of commercial vehicles, and licensing agencies may refuse to issue licenses to persons having these conditions. Refusal of permits to private drivers is, however, another question, and the evidence of the effect of a condition or defect must be more unequivocal than now exists for many of them before they can be refused licenses to drive. Studies of the effect of all types of conditions

are among pedestrians, and deaths of elderly men and children under 10 years of age contribute greatly to this number. In general, death rates are higher for nonwhite than for white persons. Exceptions are the rates for the age group 15-24, and the group over 75 years old. Married persons, especially men, have lower death rates from motor vehicle accidents than any other marital status group. Rates for divorced men are considerably higher than for other groups (fig. 2).

Health workers generally agree that further knowledge of the human factors in accident causation is needed before significant advances in highway accident reduction can be achieved. Existing knowledge on this subject has been summarized by McFarland and his co-workers (1).

The question of "accident proneness" has been explored at length, but sporadically. More than 20 years ago a review of the accident experience of approximately 30,000 drivers in Connecticut showed that a group of less than

4 percent of the operators had 40 percent of the fatal accidents, 36 percent of the injury accidents, and 38 percent of the noninjury accidents (2). In 1938 the Wichita, Kans., police department did a study of accident repeaters. Their findings have been reported in an unpublished monograph. In the intervening 20 years the number of studies to determine the characteristics of accident-prone individuals, or accident repeaters, has been legion.

The concept of accident proneness as an innate, immutable characteristic is giving way to the opinion that, because of mutable characteristics, some people in a group sharing the same environmental risks are more "susceptible" to accidents than are others in the same group. Personal factors being investigated may be conveniently divided into behavioral and attitudinal characteristics, health and physical characteristics, and effects of temporary conditions caused by such factors as alcohol, smoking, drugs, medication, and fatigue.

Behavior and Attitudes

Studies to determine the characteristics of chronic traffic law violators and accident repeaters have been many and varied, both in the armed services and in civilian groups. While gross relationships appear, many of the findings are conflicting. Moreover, application of the findings to control programs is difficult.

A study based on findings in the armed services is underway in Denver, where tests are being administered to high school children in an effort to find the factors which "discriminate" between safe and unsafe drivers. Researchers

SOURCE: Basic data from National Office of Vital Statistics.

laria death rate per 100 million mosquitoes or per square miles of swamp or the syphilis death rate per millions of spirochetes or other numerical measure of exposure.

An analysis of accidental deaths from motor vehicles, based on residence, reveals somewhat of a pattern. The 5 highest rates in 1956 were recorded for Wyoming, New Mexico, Montana, Arizona, and Idaho; the 5 lowest, for Massachusetts, Rhode Island, Connecticut, New Jersey, and New York. The "rate per miles driven" gives a somewhat different pattern and places Alabama, Louisiana, and South Carolina among the five States with the highest death rates from motor vehicle accidents. Apparently, driving is more hazardous in the south than in some other areas, although a person's chance of being killed in a motor vehicle accident are highest if he lives in the Rocky Mountain States. Based on fuel usage per capita in the United States, people in the western States drive more than those in the eastern States.

Weather is an environmental factor which obviously affects motor vehicle accidents. Because of lack of comparability of exposure data, statistics on the effect of weather, lighting, and road conditions are hard to evaluate, and the extent to which drivers compensate for obviously unsafe conditions is unknown. Statements in the newspapers, taken from gross statistics and indicating that most accidents occur on dry pavement on clear days and that the "safest time to drive" is between 2 and 4 a.m., are generalizations which have no practical value. Exposure data for rate calculations are needed in comparing the "risk" of driving under various circumstances. Fall and winter are, however, known to be the seasons of highest occurrence of accidental deaths from motor vehicles in the United States.

Surveys and Records

Data on injuries are obtained chiefly from surveys and reports from various sources. The National Health Survey is providing data from which national and regional estimates can be made. The California Health Survey provides data about accidental injuries in California. The Connecticut State Department of Health is about to undertake a family injury survey,

which should provide a wealth of information on both highway and other accidental injuries in Connecticut.

Injury reports by hospitals and physicians can provide information useful to health departments. Worcester, Mass., has an injury reporting system in operation, and in New Bedford, Mass., childhood accidents are being reported. Some such measure of the incidence of injuries is necessary for the evaluation of preventive programs, educational or otherwise.

Accident records of traffic or motor vehicle bureaus are another important and sometimes overlooked source of information to health departments. The Georgia Department of Public Health is making a study of traffic accident records to determine their usefulness in developing programs of highway safety.

The National Office of Vital Statistics has designed supplements to the death certificate which are used from time to time by some State health departments to obtain more information on motor vehicle accidents than is now available from the death certificate.

Program Evaluation

Program evaluation is a well-established procedure in all health departments. A requisite of program evaluation is a baseline of data from which to measure change. For example, if certain measures are instituted, do highway injuries and deaths decrease? Inherent in such evaluation is stability of statistics. Death statistics, of course, are comparable but may not be large enough to show meaningful trends in non-populous areas. Some type of injury measurement is necessary for determination of the results of programs of prevention of motor vehicle accidents.

Secondary Prevention

For every death on the highway more than 100 persons receive nonfatal injuries. The emergency care given an injured person is an important factor in determining whether the injury results in death, permanent disability, or recovery. The care of injured persons usually consists of first aid, transportation, and medical management of injuries. Health depart-

and impairments on accident frequency and severity are badly needed.

The accident experience of a group of persons with an impairment might be compared with the experience of a control group free from that impairment, matched by age, exposure, and whatever other variables are recognizable. A corollary study should be made on the methods of keeping records of physical condition and the details of accident causation. Because of the difficulty of selecting appropriate groups with particular defects and following their accident experience, it may be more appropriate to give complete physical examinations to a sample of drivers applying for new licenses and of older persons applying for renewals of existing licenses at a particular center. Additional tests for attitudes may also be included. By making a complete followup of drivers who are examined and selecting an appropriate control group without the defect or impairment of these drivers, the same series of observations could be used for testing various hypotheses.

Effect of Temporary Conditions

Temporary states and conditions which cause a reduction in mental awareness or diminished reflexes obviously result in an increased liability to accidents. Unquestionably, persons who are under the influence of alcoholic beverages are more likely to have accidents than those who are not, but what is the effect of low levels of alcohol present in the blood some time after drinking?

The effect of smoking on drivers of automobiles is not clear, especially when smoking is combined with carbon monoxide and with high altitudes. The effects of various drugs on human efficiency are also not entirely known, either as to undesirable side effects or induced mood changes.

When automobile drivers fall asleep, it is obvious that fatigue is accident inducing, but other aspects of fatigue are not as clear. More work needs to be done on so-called operational fatigue, which has been stated to be partly the result of frustration and conflict within the individual.

Needed studies of the effects of these various factors include: the effect of certain drugs on social behavior and emotions, and consequently

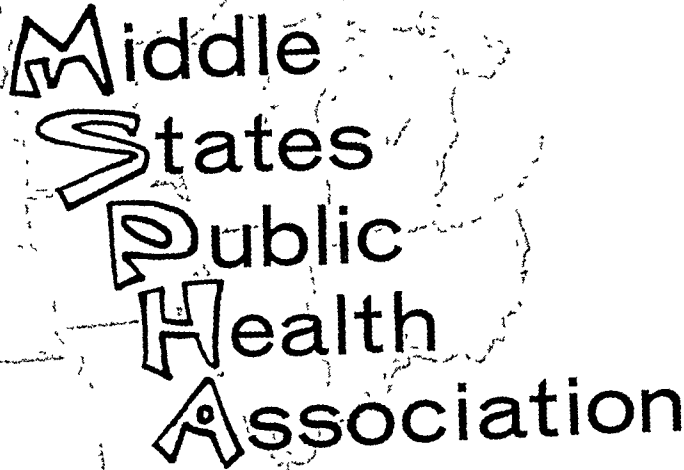

on accidents; the relationship of sleep and dozing to accident occurrence and the value of certain remedial measures; the relationship of temporary attitudes to the occurrence of accidents; the phenomenon of "road hypnosis" and factors instrumental in causing it and in reducing it; and the relationship of operator performance to levels of alcohol in the body. Many planned studies aim at determining some of these relationships. The New York State Health Department, for example, proposes a broad study of the relation of personal factors to accidents and plans to use the knowledge gained for educational and licensing purposes.

For all studies relating variables to accidents, the construction and use of an automobile simulator of high sensory and motor fidelity, which could be used to produce a variety of experimental situations under controlled conditions, would be a distinct advancement. Such a simulator would allow observation of the behavior and reaction of the driver, with a view to discovering what he does under various conditions which may lead to accidents; under what conditions he is more likely to respond poorly; the deficiencies, either in him or in his environment, that may produce such hazardous behavior, or failure to behave; and in what ways such dangerous behavior may be corrected or avoided.

Environment

When we discuss environment, we ordinarily think of geographic distribution, and because the "rate per 100,000 resident population" best expresses the extent of any health problem, this rate is customarily used in calculating geographic distribution of diseases or injuries.

Rates of motor vehicle deaths or injuries by place of occurrence of accidents, however, are usually calculated per estimated number of miles driven in an area. This rate may be appropriate for estimating the risk of accidental death while driving, but for estimating a person's chance of being killed in a motor vehicle accident, the rate per population is the appropriate one. Parenthetically, the accidental death rate is the only rate for a major cause of death which is calculated with the "agent" of exposure as the base rather than the number of people at risk. We never calculate the ma-

Middle States Public Health Association

Members from 12 States attended the ninth annual meeting of the Middle States Public Health Association, April 28-30, 1958, in Milwaukee, Wis. The following pages carry summaries of five of the papers presented at the conference.

Proposes New Category For Nonparalytic "Polio"

Minnesota's 1955-57 experience with virus diseases of the central nervous system has put epidemiologists and physicians through an exciting time, according to Dr. Herman Kleinman, chief, section of chronic diseases, Minnesota Department of Health.

The poliomyelitis surveillance unit of the State health department was established in 1955 primarily to watch, through detailed epidemiological and laboratory work, the course of poliomyelitis when the Salk vaccine was first used in Minnesota. Necessarily the unit also surveyed aseptic meningitis.

The term "aseptic meningitis" is used, Kleinman stated, to mean not a specific disease entity but a syndrome common to many entities

whose responsible agents include viruses, which primarily concern him, bacteria, and leptospirae.

Use of the Salk vaccine has made nonparalytic poliomyelitis more difficult to identify, and physicians in Minnesota are increasingly reluctant to make this diagnosis, he stated. Diagnosis has also been complicated by the demonstration that many virus agents can duplicate clinically nonparalyzing aseptic meningitis. However, diagnosis has also been clarified by the laboratory's ability to assign precisely a single virus type as the etiological agent for an increasing number of clinically similar but etiologically different disease entities. These agents, the polioviruses and the Coxsackie and ECHO viruses, come from the family of enteroviruses.

In 1955 the agent responsible for most central nervous system viral disease in Minnesota was the polio-

virus; in 1956 Coxsackie B5 virus was isolated more frequently than any type of poliovirus; and in 1957 the predominant virus was ECHO 9, Kleinman said.

The table shows Minnesota's experience with viral disease of the central nervous system for these 3 years. Kleinman pointed out that the arthropod-borne encephalitides, lymphocytic choriomeningitis, and mumps meningo-encephalitis presented no major epidemiological problems. But the remaining categories in the table, poliomyelitis, Coxsackie B5 aseptic meningitis, ECHO 9 aseptic meningitis, and aseptic meningitis of undetermined cause, were a different matter.

1955-57 Outbreaks

Although the total incidence was low, 1955 was definitely a poliomyelitis year. Poliomyelitis incidence was still lower in 1956 when

ments could well concern themselves with local methods of administering first aid.

At Cornell University, significant research is being done into the aspects of the automobile which cause or accentuate injuries. As a result of their findings, the newer cars have incorporated into their designs features such as safety locks on doors, padded dashboards, recessed steering wheels, factory installed safety belts, and the like (3).

The design of the automobile is outside the control of health departments, but other methods of preventing or minimizing injuries following accidents merit their interest. Promoting the use of safety devices, including properly installed safety belts, would seem to be a legitimate concern of health departments.

Need for Cooperation and Research

Since highway accident prevention is a concern of various community agencies, official and voluntary, cooperation between the health department and these agencies is important. A committee of representatives from these agencies might increase the contribution of epidemiological techniques, program evaluation, and other public health and medical skills to the field of highway accident prevention.

Through epidemiological research health departments can offer a challenge to physicians and others to enter and remain in the field of public health. Research "is an important key

to the grand strategy of effecting change from the traditional in public health to the newer challenges . . ." (4).

Summary

Motor vehicle accidents are amenable to the same epidemiological approach as other public health problems.

No full-scale epidemiological studies of motor vehicle accidents are now in progress, but several are planned and more are needed.

Health departments can contribute to accident prevention and traffic safety in a number of ways. Among these are promoting and assisting with driver education courses and driver improvement clinics; helping to translate the results of research into practical education; promoting systems of first aid; promoting use of safety devices, including safety belts; and cooperating with official and voluntary community agencies.

Appointments in International Health

H. van Zile Hyde, M.D., has been appointed Assistant to the Surgeon General for International Health. Horace DeLien, M.D., succeeds him as chief of the Division of International Health, Public Health Service.

Dr. Hyde's duties include liaison with the Department of State and other governmental agencies concerned with international health. He will continue as United States representative on the Executive Board of the World Health Organization. Dr. Hyde has been chief of health activities in the Institute of Inter-American Affairs and in the Technical Cooperation Administration, chief of the Middle East Office of the United Nations Re-

lief and Rehabilitation Administration, and, for the last 5 years, chief of the Division of International Health.

Dr. DeLien has directed the health program of the International Cooperation Administration in the Philippines for the past 7 years. In the extensive reorganization of the Philippine health services, he helped establish rural health units throughout the islands, rehabilitate 61 government hospitals, and provide training for public health personnel. Before going to the Far East, Dr. DeLien was associate chief of health activities, Bureau of Indian Affairs, for 8 years.

the disease is not poliomyelitis. This is the time to try to establish a definite etiology, said Kleinman.

The health department's poliomyelitis surveillance unit was impressed with physicians' stoniness in refusing to make a diagnosis of nonparalytic poliomyelitis. Unit members, impatient in 1955 with physicians who refused to make such a diagnosis at the height of the poliomyelitis season, now have only admiration for the physicians' reticence. The experience has been instructive, said Kleinman.

In 1955 and 1957 the epidemiologist was able to remove "cause undetermined" from two categories of aseptic meningitis and give the physician two new sets of references to use in his daily diagnostic routine. The epidemiologist can offer a complete picture of the signs and symptoms, indicate the relative frequency with which they occur, tell which age groups are most likely to be affected, and indicate the incubation period and the most likely mode of dissemination.

But change in the aseptic meningitides is so fast and continuous that the epidemiologist must be prepared to continue this type of work from season to season, said Kleinman. Fortunately, Minnesota had an operating poliomyelitis surveillance unit whose methods were immediately adaptable to study of the other aseptic meningitides. With it, the studies of Coxsackie B5 and ECHO 9 aseptic meningitis would have been retrospective.

Questions Raised

Kleinman listed questions raised by Minnesota's experience. Do these nonparalytic diseases have some later effect? Dr. Albert Sabin has pointed out that serologic studies show that women of child-bearing age are particularly vulnerable to ECHO 9 infection if it is present in a community. Are pregnant women really more susceptible, as they seem to be, to poliomyelitis, and if infected, will there be any effect on the fetus? The similarity of the ECHO 9 rash and the rash of rubella makes this conjecture provocative.

What is the relative antiquity of

the disease? It is tempting to believe, as Kleinman, that in past years when reports of nonparalytic poliomyelitis far outweighed reports of the paralytic disease, some of the nonparalytic cases might have been aseptic meningitis due to a then unknown cause. But divination is hazardous. Perhaps serologic epidemiology with all age groups well sampled would reveal the relative antiquity of these newly recognized viruses. This is worth trying, he suggested.

He commented on the administrative proposal that in the future, poliomyelitis be reported as such only when it is paralytic, and all nonparalytic conditions be reported under a term such as aseptic meningitis. Later the aseptic meningitis report could be qualified by designating the etiology, if it is determined. This plan would bring to the attention of health departments and epidemiologists cases which might remain unknown because present regulations do not require a report. This procedure also fits the present diagnostic temper of physicians, said Kleinman.

Rise in Reported Syphilis Preventing Neurosyphilis

The increase in the number of cases of syphilis reported in 1957 may mean fewer cases of neurosyphilis, stated Dr. Harold A. Tucker, department of clinical investigation of the Upjohn Co., Kalamazoo, Mich.

United States data for 1957 shows a peak of 135,542 cases compared with a 1955 low of 122,075. The most recent total includes 100,514 cases of late and late latent syphilis, he said.

About 25 percent of syphilitics, if untreated, develop clinical evidence of involvement of the nervous system; 5 percent will be parietic, 5 percent tabetic, and 15 percent diffuse meningovascular. Neurosyphilis is potentially even more serious than cardiovascular syphilis as a cause of mortality and partial or complete permanent disability, Tucker maintained. Therefore the 1957 case to-

tal represents an estimated 25,000 potential neurosyphilitics found and treated.

Tucker listed two factors which will tend to prevent paresis and tabes dorsalis from developing: the grace period of 12-25 years between syphilis infection and the appearance of neurological symptoms, and the success of penicillin as a brief, effective treatment for syphilis. In two recent studies of 755 patients over a 6- to 7-year period, penicillin alone appeared capable of completely curing asymptomatic syphilis of the central nervous system.

Until promiscuous sexual activity, or exposures to infected partners decrease in the Nation, we might be gratified to see annual reported totals increasing, Tucker said. This probably means that more cases are being found and treated, that contact tracing is being done well, and that serious late disease is prevented.

But no disease is ever treated out of existence, he declared. Only when promiscuity is reduced can we think that fewer reported cases reflect a reduced prevalence of central nervous system syphilis and other types of the disease.

Health Department Solves Urbanization Problems

How public health fared as Sedgwick County, Kans., doubled its population and changed its economic characteristics in less than 20 years was described by Dr. M. Leon Bauman, director, Wichita-Sedgwick County Department of Health.

The county now has 320,000 people, whose needs for adequate housing, infant and child care, and sewerage and water systems reverberated in the health department.

Overcrowded, substandard homes and 90 trailer camps at one time housed the war industry workers who flocked into the county. Old residents resented newcomers who kept cows in the backyard and threw the garbage out for the chickens.

Housing improved, Bauman explained, as tenants became home

there was a definite outbreak of aseptic meningitis due to Coxsackie B5 virus. Of the 75 cases finally accepted as Coxsackie B5 virus infection in 1956, 32 were initially reported as nonparalytic poliomyelitis, Kleinman said.

Coxsackie B5 was first suspected on purely epidemiological grounds. In August 1956, a few counties in the south central part of the State reported nonparalytic poliomyelitis with no paralytic poliomyelitis in the same area, and laboratory reports showed the isolation of cytopathogenic agents, not poliovirus, from cases in this area. "It was thus an epidemiological probability and a laboratory certainty that something besides poliomyelitis was occurring," said Kleinman.

By the end of July 1957, the great disproportion between the nonparalytic and paralytic disease of the central nervous system and the presence of a rash in a certain percentage of the cases made it certain that the new disease entity was neither poliomyelitis nor Coxsackie B5 aseptic meningitis. ECHO 9 infection was suspected and later proved, Kleinman said.

A statistical survey based on a random sample indicated that some 200,000 persons in metropolitan Hennepin and Ramsey Counties were affected through the summer of 1957.

The survey suggested a secondary attack rate of 25 to 40 percent.

There is a reporting phenomenon behind the raw data presented in the table for the category aseptic meningitis, cause undetermined, he stated. In 1955, the 47 cases now listed were originally reported as 15 cases of suspected poliomyelitis, 30 cases of nonparalytic poliomyelitis, 1 case of western equine encephalitis, and 1 case of aseptic meningitis. Poliomyelitis and encephalitis were ruled out on serologic evidence.

In 1957, physicians, mindful of the 1956 experience with Coxsackie B5 virus, reported 658 cases under such designations as aseptic meningitis, suspected nonparalytic poliomyelitis, and viral meningo-encephalitis. The 1957 column of the table shows what happened to this total as laboratory evidence accumulated. The number of cases of aseptic meningitis, cause undetermined, will be whittled down further, Kleinman said, and he predicted most of them will be classified as ECHO 9 infections. Physicians are increasingly reluctant to make a diagnosis of nonparalytic poliomyelitis, he emphasized.

Although poliomyelitis was generally distributed throughout the State in 1955, it was possible to map out six areas where cases were concentrated. In 1956 with fewer cases, localization could still be

demonstrated in three spots, he said.

The Coxsackie B5 outbreak in 1956 occurred principally in two south central counties. Kleinman interpreted this as a northward extension of what was happening in Iowa. The geographic separation of poliovirus and Coxsackie B5 virus that year was sharp, he said.

There is good reason to believe that the 1957 outbreak of ECHO 9 aseptic meningitis in Minnesota was widespread, he declared. Poliomyelitis cases that year were few and were confined to the areas of greatest population density.

High attack rates in 1956 for nonparalytic poliomyelitis and Coxsackie B5 aseptic meningitis among the young (0-9 years of age) point to an adult population that is relatively immune because of childhood exposure. But attack rates for ECHO 9 aseptic meningitis in 1957 are similar enough for ages 5 to 40 years to suggest that adults in the State had had no childhood exposure and that this infection, therefore, was new to the State, according to Kleinman.

Diagnostic Dilemma

"The diagnostic dilemma of the practicing physician can be profound and troublesome," he stated. The season of occurrence is no help because nonparalytic poliomyelitis, Coxsackie B5 aseptic meningitis, and ECHO 9 disease all occur at the same time of year. The age of an individual patient is no sure indicator of a particular viral cause.

The signs, symptoms, and cerebrospinal fluid findings cannot help to distinguish between Coxsackie B5 aseptic meningitis and nonparalytic poliomyelitis. ECHO 9 does have suggestive clinical characteristics such as the exanthem and severe headaches; in 42 percent of the Minnesota cases, the headache was described as exceptionally severe.

Perhaps the most important guidepost for the physician is the pattern of central nervous system disease occurring in a community. If there are a series of cases with none or a disproportionately small number showing lower motor neuron paralysis, then he may properly infer that

Cases of viral disease of the central nervous system, Minnesota, 1955-57

Diagnosis	1955	1956	1957 ¹

² Includes encephalitis and meningo-encephalitis of unknown etiology.

NOTE: Table includes cases admitted to diagnostic categories on serologic, epidemiological, and clinical grounds. It does not include postinfectious encephalitis occurring after measles, rubella, and chickenpox. The laboratories of the Minnesota Department of Health and the department of bacteriology and immunology, University of Minnesota, collaborated on the virus isolations.

veloped in food-handling practices, the city passed codes enabling the health department to act more effectively. The department developed a continuing food-handlers' training course which has helped to improve food sanitation, although much still is to be done, according to Bauman. In other parts of the county, food-handling practices are controlled under the rules and regulations of the State board of health.

The health department has changed along with the county, he said. After several years of preliminary work, a joint city-county health department began operating in 1950. Since then the department has taken on 11 new programs with few additions to its staff. Fewer nurses were budgeted for and less is being paid for nursing time in 1958 than in 1951, although nursing service was increased two and a half times. Sanitation visits have increased substantially, and laboratory services went up 125 percent with no increase in staff. The department moved into a new \$750,000 health center in 1957.

Some problems are solved, said Bauman, but others, such as further coordinating the various areas of the county, are still ahead. Financial support from sources other than the governments of the county and city is increasingly necessary. This may lead to a true, countywide joint board of health, instead of the present arrangement, which makes the department's director responsible to the city manager of Wichita and to the chairman of the board of county commissioners, he predicted.

Business Methods Urged For Health Services

A more effective combination of "businesslike methods and missionary spirit" in public health was urged by Dr. Albert E. Heustis, Michigan's State health commissioner, who told health workers to "do some real soul-searching before starting out to taxpayers with new baskets of provisions labeled essential to public health protection." The public, like stockholders in a

business, expects "utmost efficiency" in government health operations, he emphasized.

Health agencies should consider seriously using persons with less training to help doctors and nurses extend available services, and should look into the possibilities of "pay-as-you-grow" health services, he said.

Michigan's summer program of painting fluoride on the teeth of children was cited as an example of a self-supporting service. Carried out by senior dental students and dental hygienists under the supervision of health departments and practicing dentists, the effort is financed by nominal fees paid by parents.

"Mutual understanding between health workers and the people can reverse some of the worst and most deplorable failures in public health today," Heustis declared.

"There should be a way to persuade people to use poliomyelitis vaccine in November, rather than mobbing doctors in June. There should be a way to warn families with dreams of a home in the suburbs that unless they use care they may end up sloshing around in their own sewage up on septic tank hill. And there should be a way to impress women with the fact that a simple examination may save them from cervical cancer. We have to work harder to develop the understanding, advice, and support of the consumer," he said.

In view of changing trends and technology, health agencies should evaluate services more frequently to make sure they are keeping on course. He contended that government services in health should be planned on the basis of function rather than along more limited lines.

"The confused patterns of political boundary lines often forestall doing a workmanlike job; these ink curtains on a map keep us from delivering businesslike health protection services . . . the time is ripe right now to give up Granny's patchwork quilt."

Community health services, he asserted, can be as dynamic as the rocket age population we serve.

Community Health Work And Changing Times

The meetings of this and of the many other public health associations in the United States could well serve as the study forums for new departures in health work, suggested Dr. John D. Porterfield, Deputy Surgeon General of the Public Health Service.

"The planning and development for these departures might well spring from the many local communities which, over the years, have made America strong. Their separate tests of widely varying ideas, applied in a number of different ways, could be presented for discussion at these annual forums, and these discussions could serve as the forcing bed for new experiments along the lines of the most successful ventures being carried out. The accolade of widespread adoption given to programs initially tried in one or a few communities and the reverberations of successful health progress on the public and the Nation might well inaugurate a new and splendid chapter in the public health movement we so gladly serve."

As Porterfield noted, "The acute communicable diseases that once taxed the fullest powers of former generations of our colleagues have diminished in lethal force and are giving way to the chronic diseases, the devastations of the damaged heart and arteries, radiological hazards, air pollution, accidents, alcoholism, mental disease, and all the other problems peculiar to our age of anxiety, tension, hope, and aspiration. As a population, we grow older and increasingly are becoming victims of the many disabilities of debilitation.

"In the last half century we have passed from pioneering individualism to a mass interdependency," said Porterfield. "No man any longer goes alone. We are interconnected, interdependent, international, interracial, intercultural—in a word, we are one. Society has become an intricate organism—a social design so complex that the slightest distortion might bring on its ruin.

owners and more and better houses were built. In 1953 State legislation, drawn up by the local health department, authorized the Sedgwick County commissioners to regulate housing, sewage disposal, food-handling methods, trailer camp sanitation, water supply, and other environmental functions in certain areas of the county.

In 1957 the city of Wichita passed a housing code, designating the health department as the enforcing agency, but no funds have been budgeted for the program and it is being handled on a complaint basis. Recently the city appointed an urban renewal board, Bauman said.

Infant Death Rate

As the county's population grew, the infant death rate rose alarmingly. Crowded housing, little understanding of sanitation and medical care among the newcomers, and overcrowded, understaffed hospital nurseries may have been reasons for this, Bauman said. The health department, the Kansas State Board of Health, and a community conference at the University of Wichita aroused public attention. Physicians, acting through the local medical society, appointed for each hospital a committee of a pediatrician and an obstetrician.

The health department supplied pertinent information on infant births, deaths, and stillbirths to each hospital's committee, and the State and local health agencies reminded hospitals of the need for improvements and better staffing in their child care facilities.

The resulting progress is indicated by the fact that 1956 and 1957 are the only 2 years in which the county's infant death rate was below that of the State as a whole.

Bauman listed two other health department projects that ensued. The agency now has charge of birth and death certificates for the county and supplies hospitals with birth, death, and stillbirth figures. Physicians now report certain premature infants to the health department so that public health nurses can visit and assist mothers to understand the special needs of these infants.

A large number of working

mothers and unsuitable housing created demands for child care, and after several incidents the State board of health drew up new regulations for licensing child care homes. The local health authority is responsible for explaining the standards and regulations and evaluating the homes' maintenance of them. Although Sedgwick County has more than 100 homes licensed to care for children, the department was able to carry out this task without enlarging its staff, Bauman said.

Sewage Disposal

Wichita and other communities in the county could not extend sewage lines as rapidly as they were needed. Because people outside the city limits were reluctant to pay for extending the sewers, a number of housing developments built their own sewage disposal systems. Wichita is now ringed with systems which will be difficult to incorporate later into a unified disposal system, he stated.

The city's sewage disposal plant, operating almost at capacity before the population boom began, soon fell behind in its operations. Much sewage bypassed the plant to flow directly into the Arkansas River. During World War II little could be done about enlarging the plant, and afterwards other projects were deemed more important, Bauman said. However, with 5 years of drought, the river receded until the only water it carried was effluent below the outfall of the Wichita sewage system.

Air pollution developed as oil refinery wastes containing considerable sulfur and acid wastes from an aircraft plant were added to the city's untreated, unoxidized sewage. In certain atmospheric conditions, a misty fog of hydrogen sulfide hung over a large area downriver. After the refinery stored its wastes, the aircraft factory turned its wastes alkaline, and the city chlorinated its wastes, there was no more hydrogen sulfide, Bauman reported.

But the State board of health called Wichita a serious polluter of the river, and after a bond issue to build additional treatment facilities was defeated, the State board refused to let any more sewer lines be

built in the city until ample treatment facilities were assured. The bond issue was resubmitted and carried, and additional facilities are being built.

Wichita had disposed of its garbage by hog feeding and private and municipal collection. Often, however, the spreading suburbs and fringe areas without effective disposal methods harbored and fed rodents and flies. In 1948 Wichita had six cases of typhus fever. The health department added to its functions rodent control throughout the county.

The department also persuaded builders to install garbage grinders in most new houses. This step and residual spraying helped to control flies. Bauman feared that the problem may return because Wichita recently stopped municipal garbage collection and returned to a contract system.

Water Supply

In 1950 few towns in the county had municipal water supplies and only Wichita chlorinated its water. After intensive work by health department sanitarians, nearly all communities now have supply systems and all chlorinate their water.

Underground water can be obtained in this part of Kansas by sinking a sandpoint 30 feet, and some 15,000 people in Wichita alone have private wells. Many are carelessly constructed, and a great number are cross-connected to the city water supply. Correcting this has been difficult because of popular protest to a city commission proposal a few years ago to license private wells. The license fee was designed to pay for evaluation and control programs and also yield additional revenue.

Wichita draws its water supply from Equus beds covering a large area 20 to 30 miles away. In dry weather, large pumps in this pool create a drawdown. Public objections to this have engaged the city in continuing court litigation. The city is now negotiating for the construction of a dam on one of the nearby rivers, which would increase its water supply.

When public health hazards de-

Opiates and Opiate Antagonists

ADVANCES in knowledge of the clinical uses of the recently discovered opiate antagonists nalorphine and levallorphan in the treatment of opiate and opioid poisoning, and the use of these drugs in the diagnosis of narcotic addiction, are reviewed in this monograph. Also discussed is the abuse of narcotic drugs, including the neurophysiological and psychological mechanisms of intoxication, pharmacogenic dependence, and relapse after cure.

Clinical Uses of Opiate Antagonists

In human subjects, nalorphine produces autonomic effects resembling those of morphine, but often it also produces hallucinatory and other mental disturbances, particularly after repeated doses or large single doses. In man, nalorphine has analgesic properties, and repeated doses do not produce addiction (physical dependence), but its "side effects" impair its clinical usefulness in the management of pain. In medical practice, nalorphine has been used primarily for resuscitation of patients poisoned by overdoses of morphine, heroin, methadone, dihydromorphinone, pantopon, levorphan, meperidine, or alphaprodine. In such cases, the most prominent narcotic antagonistic effects are those exerted on respiratory depression. In subjects addicted to morphine, methadone, heroin, and many other opiates and opioids (except possibly meperidine), nalorphine precipitates acute "abstinence syndromes" and has therefore been used clinically in the diagnosis of active addictions. Analysis of dose-effect relationships both in man and in animals suggests that nalorphine and its analogs exert their "specific" narcotic-antagonistic actions by (a) "molecular competition" and (b) "unmasking" of the processes responsible for the opiate and opioid abstinence syndromes.

Narcotic Drug Abuse

The problems of narcotic drug abuse include "euphoria," "addiction," and "habituation,"

and these are considered both from the neurophysiological and psychological viewpoints.

The distinction between "positive" and "negative" euphoria is discussed, and the latter is considered mainly from the standpoint of mechanisms involved in the production of morphine analgesia.

Neurophysiological data obtained chiefly in studies on "analgesic-test" reflexes in animals indicate that morphine exerts selective depressant actions on interneuronal activity in the spinal cord, medulla, midbrain reticular forma-

MONOGRAPH

No. 52

The accompanying summary covers the principal findings presented in Public Health Monograph No. 52, published concurrently with this issue of Public Health Reports. The author is with the National Institute of Mental Health Addiction Research Center, National Institutes of Health, Public Health Service, Lexington, Ky.

Readers wishing the report in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Wikler, Abraham: Opiates and opiate antagonists. A review of their mechanisms of action in relation to clinical problems. Public Health Monograph No. 52 (PHS Pub. No. 589). 39 pages. U. S. Government Printing Office, Washington, D. C., 1958. Price 30 cents.

"The problems that confront us today are not one-agency problems. Aging, for instance, presents challenges that cut across many departmental lines—public health, social welfare, mental hygiene, hospitals and nursing homes, rehabilitation, and others. Similarly, the chronic diseases, though principally the responsibility of health departments, are also interdepartmental, inter-agency, interfacility responsibilities. To achieve our ends in these fields will require a harmonious coordination of planning and effort, of institutions and agencies, of citizen

groups and professional organizations, of concepts and methods."

However, Porterfield pointed out, the present era holds high promise. "In our complexity there is strength, and in our enforced oneness there is a will that could triumph. We are at least dreaming of a future in which men may be truly free of despair and disease, of hopelessness and fear. We shall have to make that future soon, if at all. We have the earliest threads of that grand design in our fingers. To weave them properly will require the great-

est exertion of our imaginations, our insight, instinct, and educated skill."

Porterfield believes that these new public health programs can be created and that the challenges of the changing times will not daunt or threaten us. We will find ways through the social wilderness to successes greater than any we now think possible, he said. He feels sure that all health workers share with him "the dynamic belief that man as a social being can achieve, within the limits of his physical universe, his own desirable destiny in health and well-being."

Sanitation

Authority to act against future danger to health—*Board of Health of the State of Maryland et al. v. Edward J. Crew*, 129 A. 2d 115 (1957).

A State statute conferred upon the Maryland State Board of Health authority to order the abandonment or to prevent the construction of a private well which is or which may become prejudicial to health, whenever a system of water supply serving the public is directly available. Appellee, dissatisfied with the available public water supply, dug a well within 60 feet of his septic tank in violation of regulations prohibiting wells within 100 feet of a source of pollution. Ordered to abandon his well by the board of health, he sued for an injunction restraining enforcement of the order, alleging that the order was unlawful, unreasonable, and deprived him of property without due process of law. The lower court in issuing a perpetual injunction held that the board not only failed to show that the well was prejudicial to health but failed to show a reasonable possibility that it might become so.

In reversing the lower court, the court of appeals held that the statute itself, which required compliance with standards designed

to protect the public health, is a proper and constitutional legislative exercise of the police power. Second, it held that at the time of the board's order, although there had previously been an interruption in service, the evidence revealed that an adequate and safe public water supply was available to appellee, a condition required by the statute before the board could issue the order. Finally, the evidence showed that although the water in the well was pure at the time of the order, contamination might and probably would occur at some later date. The court said that "protection of the public health is not required to wait until contamination is shown to exist" and held that the legislature contemplated that the board could act where its observation of conditions, in the light of scientific knowledge of probabilities that might occur in the environment, led it to believe that health might be affected. Accordingly, the order requiring abandonment of the well was declared to be neither unreasonable nor unnecessary and was upheld.

Operational Planning in Civil Defense for Environmental Health

KENNETH C. LAUSTER, M.S.P.H.E.

TECHNICAL preparations for the eventualities of a disaster are of little value without an operational plan describing the course of action to be taken in a given contingency. The operational plan says in specific terms who does what, when, and how. It is the mainspring of civil defense work.

There have been many activities in civil defense planning over the past two decades. One, the mutual aid program for waterworks, begun during World War II, is still carried on in many areas and serves a useful purpose. Following the 1955 floods in Pennsylvania, this program was the principal means for the emergency restoration of many damaged or destroyed waterworks.

Volumes have been written about the technical aspects of civil defense and natural disaster problems. These have been issued by the Federal Civil Defense Administration (since July 1, 1958, combined with the Office of Defense Mobilization to form the Office of Civil and Defense Mobilization), the Public Health Service, State and local departments of health, the Armed Forces, professional and technical associations and societies, the American National Red Cross, and the National Research Council Committee on Disaster Studies. The suggested reading list for civil defense health services includes only a small part of the avail-

able literature, yet the titles cover four typewritten single-spaced pages. There is no dearth of technical information for those desiring it.

A considerable amount of training has been undertaken by the Federal Civil Defense Administration through its Staff College and Radiological Defense School, by the Department of Agriculture, by the Department of Defense, by the Public Health Service, and by the Food and Drug Administration, although some of the PHS courses and the FDA courses were suspended on July 1, 1957. The radiological health training course, conducted for years by the Public Health Service at the Robert A. Taft Sanitary Engineering Center in Cincinnati, is continuing.

The result is a considerable reservoir throughout official health organizations of technically informed professional personnel whose services would be invaluable in disasters. However, plans to use their competencies effectively were inadequate or nonexistent. The big void was in the development of operational plans tailored to current planning assumptions which are based on enemy capabilities. These assumptions are set forth in detail in FCDA Advisory Bulletin No. 204.

The major threat is attack by thermonuclear weapons in the megaton range. There is no defense against this weapon except distance and shielding. If we had shielding or blast shelter, our plans would utilize them. But in their absence, the only protection is not to be near the weapon when it detonates. Hence, the Federal Civil Defense Administration recommended the broad policy of evacuation as the best means of saving a substantial portion

Mr. Lauster is sanitary engineer consultant with the Health Division, Plans and Readiness Office, Office of Civil and Defense Mobilization, Battle Creek, Mich. The article is based on a paper presented at the Michigan Public Health Association meeting in Detroit, May 8, 1958.

tion, lateral posteroventral, and certain of the medial thalamic nuclei and cerebral cortex, while also exerting excitant actions at all levels and augmenting supraspinal inhibition.

Evidence acquired in studies on both man and animals indicates that one of the important psychological actions of morphine is reduction of pain-anticipatory anxiety. Other actions of morphine that may be involved in the production of euphoria are discussed with particular reference to personality factors.

The neurophysiological effects on the morphine abstinence syndrome of bilateral frontal lobotomy and physiological "transection" of the spinal cord in man (due to disease), and of decortication and spinal transection in the dog, indicate that the processes responsible for addiction operate at cellular (neuronal) levels throughout the neuraxis and appear to involve "counter-adaptations" to the depressant effects of morphine on interneuronal activity. While data obtained in frontal lobotomized patients and in monkeys subjected to bilateral frontal lobectomy, bilateral cingulumotomy, or bilateral ablation of the cingulate gyri are conflicting in some respects, it appears that although the integrity of the cerebral cortex and its connections with subcortical structures is necessary for the expression of "purposive" abstinence phenomena, the "nonpurposive" features of the morphine abstinence syndrome are integrated to a very large extent subcortically. In addition, studies on man indicate that during morphine addiction, adrenal and gonadal activities are depressed, probably through an indirect effect on the pituitary gland, and that transient "rebound" adrenal hyperactivity occurs on withdrawal of the drug.

In considering the psychological aspects of addiction, it is stressed that with the development of tolerance the "euphoric" effects of morphine become progressively attenuated, but that new sources of gratification are developed as a consequence of the progressively intensified "need" for the drug. The "rewarding" effects of morphine include the periodic relief of "craving," the sense of achievement engendered by successful pursuit of drug supplies ("hustling"), and social acceptance of the user by other addicts. Also, the suffering attendant upon abrupt and complete withdrawal of the

drug may serve some addicts as a means of expiating guilt.

The role of "conditioning" in the genesis of relapse (habituation) is discussed from both "classical" and "instrumental" theoretical viewpoints. A number of suggestive, but not conclusive, observations indicate that the opiate abstinence syndrome may become "conditioned" to regularly associated environmental stimuli. If verified, such a process could account, in part, for the motivation to relapse under certain circumstances long after the "unconditioned" morphine abstinence syndrome has subsided. Data more strongly supported by experimental evidence, obtained in rats, indicate that the recurrent reduction of abstinence distress during maintained morphine addiction can result in reinforcement of such of the organism's activities as culminated regularly in administration of the drug, and that in consequence, "drug-seeking" behavior may persist beyond the duration of the "unconditioned" abstinence syndrome.

It appears likely, therefore, that the probability of relapse is not only a function of the initial "euphoric" effects of opiates, which diminish rapidly as tolerance develops, but also of the cyclic actions of these agents in generating dependence and in relieving abstinence symptoms. These actions persist as long as the opiates are administered at sufficiently high dose levels and at sufficiently frequent intervals. The probability of relapse is also related to the extent to which the administration of these drugs is brought about by actions of the organism upon its environment. In addition, theoretical considerations suggest that "secondary reinforcers," or stimuli regularly associated with reduction of abstinence distress during maintained addiction, may serve as incentives for subsequent relapse.

Although practically nothing is known about the neurophysiological mechanisms operating in relapse, progress in that direction, as well as in the further elucidation of the psychological processes involved, may become possible with continued improvement of recently developed techniques for demonstrating in animals a "model" of this most important of all problems of drug abuse.

stances the success or failure of the operational plan becomes the success or failure of civil defense as a whole.

As control is reestablished, the flow of information and intelligence resumes, enabling the chief executive to operate in accordance with the situation. His future actions and orders are customarily expressed with reference to the operational plan, and often as modifications of it.

The entire process of meeting massive damage throughout an area depends on the soundness of the operational plan. The people's will and ability to resist, to save lives and property, to restore a community to a state approaching normal living, and ultimately to safeguard the productive capacity of the Nation, all are rooted in the practicability of the operational plan and the proficiency of its working organization.

Most of the work already done in the States under the survival planning program has been confined to the development of an organization and an operational plan at the State level and State-district level. This is essential to provide a frame of reference for lower echelons as they prepare their own plans. Without it, two or more cities may expect to use the same facilities in their civil defense plans.

To date these plans are generally sketchy, and to make them truly operational will require considerable study and revision by the people charged with the responsibility for carrying them out. It is imperative that the people assigned places in the organization be fully aware of their positions and their duties and responsibilities. They must also know to whom they are responsible, where they report, what they have to work with, and other details. These same people must be consulted in the planning so that the ultimate blueprint for action is tailored to their capabilities.

The general method of approach in most States is to assign to a staff member or members the responsibility of developing the operational plan. This is an appropriate procedure, and experience has demonstrated that an initial draft of the plan will be ready in the shortest possible time. However, unless the staff then studies the plan thoroughly, making appropriate revisions and additions, and becomes thoroughly familiar with it, the plan is worthless.

Health departments throughout the country too often are not aware of this planning and take little or no interest in it. They seem to feel that their civil defense readiness is complete if someone is assigned to prepare a plan.

Actually, at this point the essence of planning begins. For at this stage the people who are responsible at the grassroots begin to act.

Furthermore, in the event of an enemy attack, health authorities can never hope to provide much more than the nerve center of the total organization needed. But around this center the various kinds of auxiliary personnel must be assembled to accomplish the tasks of restoration.

Sanitation and Civil Defense

In all of the plans of the various States engaged in civil defense planning that I have seen, sanitary engineering and sanitation are always considered. In many instances, it is the only public health program mentioned. Why, I do not know. I like to think it is because the public recognizes sanitation as the foundation of public health work. Perhaps a lack of professional guidance has resulted in the omission of some important public health programs. Or possibly, after a study of the situation the realistic conclusion drawn, based on the limits of capabilities, is that all efforts must be concentrated on sanitation to provide maximum return for effort expended.

What are the specific responsibilities of the sanitary engineer and the sanitarian? Certainly they encompass all of the customary ones, complicated by the possible use of chemical warfare contaminants, biological warfare contaminants, and radioactivity. At the minimum, the sanitary engineer must be prepared to protect water, milk, and food supplies from all normal contaminants and those introduced overtly or covertly by the enemy.

The technical aspects of this task should not be completely overwhelming. It is clear that sanitarians and sanitary engineers must equip themselves to handle the problems associated with radioactivity in this age when the atomic energy industry is rapidly mushrooming. This capability must be developed as one more public health concern.

of the people. Application of this policy must depend upon local circumstances. The determination of whether to evacuate or not is the responsibility of the States and communities.

The threat of biological and chemical warfare agents is not being overlooked. A growing school of thought holds that, as the thermodynamic capabilities of the prime adversaries reach a stalemate, biological and chemical warfare agents are likely to take on increasing importance.

The Gap in Civil Defense

In observing the civil defense preparations being made throughout the country, it was noted that the most important phase, operational planning, was being neglected, largely because of the States' inability to finance the development of operational plans. All technical preparation is of little or no value without an operational plan which assigns functions and areas of responsibilities to the people in governmental positions. They must know the who, what, where, when, and how of their community's civil defense plans. They must know who is the boss, who takes the boss' place when he isn't there, and who replaces the substitute boss when he is not there. They must know what equipment and supplies are available and where they are to be found. They must know how to obtain transportation and how and with whom to communicate.

As the history of disasters reveals, chaos is almost inevitable when there is no operational plan to control and direct the forces attempting to give aid. The account in FCDA Technical Report 11-2 of the Arundel Park fire in Baltimore contains a typical incident. A physician residing in the neighborhood took his bag and went to the fire to help. He reported seeing confusion and elements of panic. He gave first aid, administered drugs he had with him, marked each patient with the medication and the time it was given, directed ambulances not to converge on the nearest hospital, and advised about 100 of the injured to see their own doctors. He soon ran out of supplies.

The only other sources he knew of were the first aid kits of fire wagons and ambulances. Too late he discovered that supplies were avail-

able from local druggists, and that a health center and casualty clearing station where stretchers, dressings, and antibiotics were stored was only a few blocks away.

A county health officer received no notification of the fire until he heard of it on the radio at his home in Annapolis. He rushed to the site but arrived after all casualties had been evacuated. Although he was chief of the organization planned to handle disasters, he was powerless to make the organization effective because physicians were not aware of the disaster plan.

Realizing the importance of operational plans and their lack in most areas, the FCDA launched a survival planning program some 2 years ago. This program is entirely financed by Federal funds through contracts with the States. The States hire the personnel and do the work under the terms of the contract. Some 47 States and Territories are now engaged in this activity.

The Plan's Function

The operational plan is the joint product of the area's chief executive, such as the governor or the mayor, and his staff. However, once the chief executive has approved and adopted the plan, it becomes his personal standing order and he takes complete responsibility for it. Prior to putting it into operation, the plan is subject to continual review, revision, refinement, and amendment, and all improvements in organization, training, and equipment are a part of the plan.

Destruction of communications and facilities by enemy attack will make it impossible for the chief executive to influence the actions of emergency forces for periods ranging from a few minutes to several hours or days. Therefore, control during this period may be decentralized, down to single service units of a few persons. Not until communications have been restored can the chief executive again influence action.

At this point of decentralization the operational plan is vitally necessary. As the standing order of the chief executive, it substitutes for his personal instructions until his control has been reestablished. Under these circum-

Efficacy of Chloramphenicol Therapy for Typhoid Carriers

MARY E. O'CONNOR, Dr.P.H.

THE VALUE of chloramphenicol in the treatment of typhoid fever has now been well established, but a question remains as to what effect, if any, therapy with chloramphenicol has on the prevention of the chronic typhoid carrier state.

Even before the use of the antibiotics, many attempts were made to find an agent that might be effective in eradicating the focus of typhoid bacilli in the chronic carrier. Search through the literature, to be described shortly, reveals many experiments with many different drugs and combinations of drugs, but these have been unsuccessful, or, if successful, have lacked confirmation. Some investigators reported cures, but in most instances they had reference to temporary or convalescent carriers and not to chronic typhoid carriers. This paper deals only with the chronic typhoid carrier state. Carriers are defined as persons who have not suffered from typhoid fever within the previous 12 months but discharge typhoid bacilli. They may or may not have had a clinically recognized attack of typhoid fever, but they excrete the organism over a period of at least 1 year. Chronic carriers who shed typhoid

bacilli at irregular intervals are sometimes called intermittent carriers.

In the absence of a reliable method of terminating the carrier state, particular interest centers in the possibility of preventing its development by the modern methods of treating the acute infection. The study here reported was designed in the summer of 1952 to evaluate the results obtained when cases of typhoid fever were treated with chloramphenicol. Data collected on 1,413 cases from Mississippi and Louisiana suggest that chloramphenicol has no marked effect on the prevention of the typhoid carrier state.

With the rapid reduction in the number of cases of typhoid fever, however, there is a corresponding reduction in the number of carriers. Feemster and co-workers attempted to collect figures on the number of typhoid carriers in the United States, but there was so much variation in the information available from State health departments that the tabulation was not satisfactory (1). However, figures are available for Massachusetts, with an estimated prevalence of approximately 25 per 100,000 population (2); for New York, 42 per 100,000 population (3); and for Mississippi, 228 per 100,000 population (4). Typhoid carriers still constitute a sizable and important problem.

The medical, socioeconomic, and psychological importance of the typhoid carrier problem has led many clinicians to seek medical treatments rather than cholecystectomy for the cure of typhoid carriers. Stertenbrink in 1928 reviewed the earlier German literature on this

Dr. O'Connor, with the Communicable Disease Center, Public Health Service, at the time this study was made, is now with the Division of International Health, United States Operations Mission, Addis Ababa, Ethiopia. The paper was submitted in partial fulfillment of the requirements for the degree of doctor of public health, Tulane University School of Medicine.

The same attitude can be applied to chemical warfare agents. The nerve gases are second cousins to the newer insecticides being used so widely in insect control and agriculture. Sanitarians must know how they are being utilized. We have been familiar with the biological warfare agents for years. However, the disease manifestations from various modes of dissemination may become extremely perplexing and cause much damage before they are ultimately brought under control.

How can we assume these added responsibilities when our overburdened staffs cannot discharge all the duties now placed upon them? This dilemma has always been with us. The only answer is that we must find ways of accepting these responsibilities because if we do not, someone else will assume them. And that would fractionate still further the health activities which are already too fractionated. If we provide the leadership and the coordination for those who do express an interest in these matters, we can retain in official health agencies those activities which rightly belong to them.

In attempting to envision the conditions of modern war, it is important that we think of a program based on facilities prevailing a half century ago. Initially, fallout may prevent movement in many areas. Communications will be disrupted and electric power unavailable, with a consequent lack of heat, light, refrigeration, sewage disposal, and water supply.

We must prepare to exist on our local resources, possibly for weeks. OCDM recommends that each family prepare to remain within its own home for no less than 14 days. Any immediate aid following an attack must be local in origin. No State should plan for or expect to receive any assistance from outside sources or from the Federal Government for at least 30 days following an attack. However, Federal aid will be forthcoming as soon as it is humanly possible in the circumstances.

In making operational plans for emergency action today, we must never forget the possibility that this threat will be with us for a long time. In designing, constructing, and re-

constructing sanitary facilities, we should think of reducing their vulnerability to blast effects, and of their functioning during power interruptions. Although we recognize our dependence on central sources of water and power and on central systems of sewage collection and disposal, we must consider the advisability of building into these systems the maximum degree of self-sufficiency at the lowest possible level of operations.

Achieving Readiness

Four principal survival measures are necessary to achieve a state of readiness. They are:

- The establishment of emergency lines of succession for key personnel in the organization.
- The preservation of records essential to continued functioning and emergency actions.
- The establishment of emergency locations for operations.
- The full utilization of all personnel, facilities, equipment, and supplies for emergency operations.

The first three measures are relatively simple to accomplish, but they are absolutely essential and must be part of any planning. The fourth is far more difficult.

How many civil defense organizations know what personnel, facilities, equipment, and supplies are available for emergency sanitation operations? How many have made a study of what would be needed to accomplish such a task in the kind of disaster we may encounter? After such studies, what balance was struck between what is available and what might be needed? What are the deficiencies and what action is being taken to overcome them?

These are some of the environmental health aspects of civil defense. Basic to them, and to all other civil defense activities, is operational planning. This planning must be done by those who will be responsible for putting it into action. The plan is merely a record of what has been undertaken and completed by official health agencies. The plan itself is nothing, but planning is everything.

necessitated visits to private physicians and to homes of the patients. Pertinent information was transferred to cards for tabulation. Each record was carefully analyzed and evaluated. Reported cases that were considered not to be typhoid fever were omitted from the study. The cases rejected because of insufficient evidence to diagnose them typhoid included probable instances of such diseases as brucellosis, paratyphoid fever, cancer, tuberculosis, amebiasis, pneumonia, murine typhus, histoplasmosis, and tularemia. These were proved later by bacteriological and other diagnostic examinations to be these diseases. Other cases which were undoubtedly typhoid fever were excluded because of inadequate data as to treatment or because of inadequate followup in instances of moving, inability to locate, loss of hospital records, and death. Fifty-three cases in all were rejected.

Diagnostic Criteria

The remaining 1,413 cases presented the usual clinical features of typhoid fever. Furthermore, the diagnosis was proved in more

than half of the cases by recovering *S. typhi* from the blood, feces, urine, pus, or spinal fluid. In most of the remaining cases, the diagnosis was based on serologic grounds, plus clinical symptoms and epidemiological evidence, or, in a relatively few cases, on epidemiological association with bacteriologically proved cases. The cases diagnosed on serologic evidence either demonstrated agglutinins in the blood which reached levels of diagnostic significance with anti-O titers of 1:640 and anti-H titers of 1:1280, or higher, or manifested at least a fourfold rise in agglutinin titer. Many of the cases diagnosed on serologic and epidemiological evidence were part of large outbreaks.

All reported typhoid cases were investigated by the local health departments. Specimens of blood, feces, and urine were collected as part of the routine epidemiological investigation of typhoid and suspected typhoid cases and the families of the patients. The Mississippi and Louisiana departments of health require that the cultures of at least two feces specimens and two urine specimens be negative for *S. typhi* on all reported typhoid fever cases before

subject, analyzing the results achieved with the use of more than a hundred different therapeutic agents (5). He concluded that none of the methods was successful or even held promise. With the advent of the sulfonamide derivatives, new tests were devised but these likewise proved disappointing (6,7). After Bigger demonstrated the in vitro synergistic action of penicillin and sulfathiazole on *Salmonella typhi*, these drugs were used by several groups of workers in the treatment of chronic typhoid carriers (8). Korns and Trussell reported no cures (9). Smith and others state that sulfonamides and penicillin are ineffective in therapeutically attainable levels but that the newer antibiotic, chloramphenicol, seems more promising (10). However, numerous reports, among them Stryker (11) and Nichols (12) suggest that treatment of chronic carriers with chloramphenicol results merely in temporary cessation of the shedding of bacilli. A more recent possible exception to the usual experiences is reported by Carnes and associates who state that 6 of 7 carriers were cleared up by preparing them for drug therapy with chloramphenicol by an intensive course of typhoid immunization (13).

Materials and Methods

The study reported here was carried out over a period of 3 years, and the data were collected on cases occurring from 1947 through 1952 in Mississippi and Louisiana. The two States are comparable in many respects: As of the 1950 census, the population of Mississippi was 2,178,914 and of Louisiana, 2,683,516; both States have large rural areas; both are in the South Central region and have approximately the same incidence of typhoid fever; and the counties and parishes are well supplied with local health units. The use of chloramphenicol did not become widespread until late 1949. Therefore, while most of the typhoid fever cases in the control group occurred from 1947 to 1949, most of the treated ones occurred from 1950 to 1952.

The study population was divided into four groups according to the treatment received: those receiving no chloramphenicol and referred to as nonspecifically treated; those re-

ceiving inadequate total dosage of chloramphenicol; those receiving adequate total dosage initiated before the 15th day from onset of illness; and those receiving adequate total dosage initiated after the 15th day from onset of illness. Only those patients receiving chloramphenicol in dosages of 30 gm. and over were considered adequately treated. In 1950, the drug manufacturer revised the dosage of chloramphenicol (Chloromycetin) to an average of 30 gm. per patient to be given over a period of approximately 14 days. This was the dosage considered "adequate" in this study. Children received proportionate amounts of the drug equivalent to the adult dose on the basis of body weight.

Data were obtained from morbidity reports, hospital records, mortality reports, laboratory reports, epidemiological records in the local health departments, private physicians, pharmacists and reports of field investigations of cases. I investigated all reported cases of typhoid fever in Mississippi during 1950 to 1952 and part of 1949.

All identifying data on typhoid fever cases reported to the two State health departments during the study years 1947 through 1952 were recorded on a master list by year of report and by county or parish. These data included the hospital number and the name of the reporting physician. A list of the cases was then sent to the local health department with a request for the epidemiological record on all cases that had occurred in the county or parish during the study years. After copies were made the original records were returned to the local health departments. As the records were completed they were filed alphabetically, and were then taken to the hospitals where data from the hospital record were transferred to the study record. New records were made on those cases diagnosed by the hospitals as typhoid fever but not reported to the States. I then visited the State laboratories and obtained lists of all cultures reported positive for *S. typhi* during the study years. This information was added to the epidemiological records if it had not already been recorded.

Where information was incomplete, visits were made to the counties and parishes to obtain missing data. In many instances this

¹ Week after onset.

² Includes all cases from which stool specimens were obtained, whether or not bacilli were found in any specimen. "First negative" means first negative specimen after which no positive specimens were obtained.

³ Includes permanent carriers and persons who remained as temporary carriers for periods ranging up to 8 months.

⁴ Total dose with course begun before 15th day of disease.

⁵ Total dose but course initiated on or after 15th day of disease.

⁶ Inadequate total dose without regard to time of initiation of treatment.

⁷ Includes penicillin, sulfonamides, streptomycin, fever pills, and aspirin.

The ratios of male patients to female patients were 1.2:1 in Louisiana and 1.3:1 in Mississippi. Gross attack rates were higher in Louisiana than in Mississippi.

In table 2 the 1,413 cases are distributed by type of treatment and by the criteria upon which the diagnosis was based. Eight hundred and thirty-seven, or 59.2 percent, were diagnosed by isolation of *S. typhi*. Of these, 310, or 37.0 percent, had positive blood cultures; 297, or 35.5 percent, had positive fecal cultures; and 230, or 27.5 percent, were positive for *S. typhi* in both blood and feces. Five hundred and five, or 35.8 percent, were diagnosed on serologic evidence, and only 71, or 5.0 percent were diagnosed on the basis of epidemiological association. A greater percentage of positive

specimens were found among nonspecifically treated persons than among chloramphenicol-treated persons (64.2 vs. 55.4), whereas the reverse was true for serologic evidence (30.6 vs. 39.7). The percentages of epidemiological diagnoses were nearly identical (5.2 and 4.9). These differences are similar for each State although Mississippi had 5.2 percent more patients diagnosed by positive culture, slightly fewer diagnosed on serologic evidence, and twice the percentage diagnosed on epidemiological evidence.

Tables 3 and 4 show the relation between treatment and the percentage distribution of cases according to the week after onset in which was collected the first fecal specimen negative for *S. typhi* and not followed by a positive

patients are released from isolation and public health supervision. Sheppard-Keidel vacuum bleeding tubes were used to take blood for culture and serology, and standard 10-dram, screwcapped glass bottles containing a preservative were provided for feces and urine specimens. With few exceptions all culture work was done by either the laboratories of the State health departments or in Louisiana by the Charity Hospitals. Materials and methods used for culture and serology in the major laboratories were of approved types and were not changed importantly during the 6 years of the study.

Additional Followup

As part of the followup, a series of feces and urine specimens were obtained during 1953 on all patients whose cultures had been found positive for *S. typhi* intermittently for 2 months or longer during or after convalescence. This followup also included those cases which had not been reported to the State health departments by the hospitals and any cases which in the opinion of the writer, had not been ade-

quately investigated. All told, approximately 780 cases were re-investigated in this manner. As a result of this followup four persons who previously had been discharged following chemotherapy and two negative feces and urine cultures were confirmed as chronic typhoid carriers. By investigating some of the sources of these reopened cases, other chronic carriers were found and were placed under public health supervision. A considerable amount of the "shoe-leather" epidemiology was done by the public health nurses. I also visited and obtained specimens on numerous cases in the study.

Results

Table 1 shows the distribution of all study cases of typhoid fever in Louisiana and Mississippi by age, race, and sex. The table also presents the rates per 100,000 population for the 6-year period 1947 to 1952. In both States the highest rates were found in the groups aged 5-9 and 10-19 years, with those 40 and over showing the lowest rates. The rates were higher among the nonwhites in all age groups.

patients (8 in an overall total of 799, or 1.0 percent) than among those given no specific treatment (12 out of 614, or 2.0 percent), the difference in rates is not significant. Thus, while the data are compatible with the idea that specific treatment reduces the carrier rate somewhat, they clearly do not prove it.

Table 6 presents the relation of intensity of specific treatment to relapse and death. It is interesting to note that when adequate dosage of chloramphenicol was given early, before the 15th day, the rate of relapse was 5.2 percent, practically the same as for the series with no specific treatment, 5.8 percent. In contrast, the group who had adequate treatment after the 15th day had a relapse rate of 21.5 percent, approximately the same as for the group who had inadequate treatment (21.9 percent). Those adequately treated before the 15th day had the lowest case fatality rate, 1.9 percent, whereas the group given no specific treatment had the highest rate, 8.1 percent. The rates for the series given adequate treatment but after the fifteenth day and for that series given

inadequate treatment were essentially the same, 5.0 percent and 5.1 percent respectively.

Discussion

A field study of the type described has some obvious limitations as a method of studying the efficacy of chemotherapeutic agents. Many of the epidemiological record forms used were not really adequate for collecting and recording data pertinent to such a study. For instance, these forms had no specific blocks for recording treatment, name of hospital, admission and discharge dates, clinic or dispensary number, or name of county. The spaces allotted to the environmental history and laboratory data were very inadequate. It would have helped considerably in differential diagnosis to have had a checklist for clinical history, physical findings and course of treatment, with space for history of onset of illness and sequelae. Since adequate supervision cannot be given by the local health departments to patients with communicable diseases who are not hospital-

1-7 See table 3.

specimen. Since the separate data for the two States are closely similar, attention need be directed only to the combined data for both States. From table 3 it appears that the greatest proportion of reversions occurred during the second week for the group given early adequate treatment, whereas it occurred in the fourth to sixth week for all other groups. Progress in clearing the fecal infection is shown more clearly, perhaps, by the figures for the cumulative percentages in table 4. Excluding the group which received delayed though adequate treatment and in which few isolations were attempted during the early weeks of the disease, the proportion which had permanently reverted was greater at each interval among those given chloramphenicol than among those treated nonspecifically. The most rapid clearing, of course, was in the group treated both early and adequately. In this group nearly half (48.7 percent) became negative during the second week as compared with 29.9 percent of those given only nonspecific treatment.

Twenty chronic carriers, 10 in each State,

were found among the 1,413 cases of typhoid fever in Louisiana and Mississippi. Table 5 shows the pooled data of the two States, with distribution of cases by age and sex only. In agreement with long-standing impressions, in all treatment groups carrier rates were higher among persons 20 years old and over than among younger persons. Combining all groups and the data from both States shows that the carrier rates were 0.7 percent for 851 patients under age 20, 1.9 percent for 363 patients aged 20-39 years, and 3.5 percent for 199 patients 40 years old and older. With regard to sex, the overall differences are in opposition to the usual experience but are trivial. The 782 male patients yielded 12 carriers, or 1.5 percent, whereas the 631 female patients yielded 8 carriers, or 1.3 percent. However, in the group with the highest number of carriers, those 40 years of age and older, the expected situation prevailed, with 5.2 percent of the females becoming carriers but only 2.4 percent of the males. Finally, while there were relatively fewer carriers among the specifically treated

situation is somewhat different. That *S. typhi* was not recovered from the feces of 886 or more than four-sevenths of the entire group as a whole was very largely due to failure in many instances to collect stools for test during, or soon after, the acute phase of the illness. However, the data indicate rather clearly that treatment did exert an influence on the detected excretion of typhoid bacilli. As shown in table 2, in Louisiana positive stools were found in 142 of 486 treated patients (29.2 percent) and in 215 of 424 untreated patients (50.7 percent); in Mississippi, the figures were 83 of 313 treated (26.5 percent) and 87 of 190 untreated patients (45.8 percent). Furthermore, as shown in table 4, adequately treated cases tended to become permanently negative earlier (69.4 percent during or before the third week) than the untreated cases (only 45.2 percent by the same time). It should be emphasized, however, that treatment did not eliminate bacilli from the feces with any uniformity. In 81 cases feces were positive during therapy and in 130 after cessation of therapy.

Other factors also probably influenced the data as to fecal excretion of *S. typhi*. In uncontrolled field situations where specimens are collected at irregular intervals, it obviously is difficult to know the precise time when patients cease to excrete typhoid organisms. For purposes of tabulation, I have arbitrarily chosen the time intervals used in table 3 and have entered cases in the table as of the week of collection of the first feces or urine specimen negative for *S. typhi* not followed by a positive culture. Specimens were not submitted from all patients every week nor were they collected on the first day of the stated intervals.

In this study, an effort was made to determine the relation of the persistence of typhoid bacilli in feces to the degree and time of initiation of specified treatment. However, the frequent failure to collect stools for testing during the acute phase of typhoid fever makes it impossible to speak with assurance about the number or proportion of stools positive at any specific stage of the disease. The only definite statements that can be made are that, in any given case, stools taken on or after a certain date were negative and that by a given period after onset in a certain proportion of cases ex-

cretion of the bacilli had permanently ceased. These latter figures, obviously, are minimal since, if stools had been collected earlier or more frequently, the assigned date of cessation would have been advanced in many cases.

Of special interest in this study is the excretion of bacilli in the feces beyond 6 weeks from date of onset of typhoid fever. Of the 273 patients not declared permanently negative for *S. typhi* at the end of 6 weeks, 217, or about 16 percent of the total 1,380, were actually found to be excreting the organism at a later time (table 3). Patients determined as having ceased excretion of bacilli numbered 136 in the 6- to 8-week interval, 69 in the third month, 21 during the fourth month, 11 in the fifth month, and 16 during the next 3 months, leaving a total of 20 permanent or chronic carriers, 8 among the chloramphenicol-treated group and 12 among the group receiving non-specific treatment (table 5). Treatment, incidentally, did not appear to be an important factor in this group. The data in table 3 do suggest that in Mississippi a higher proportion of cases were found excreting the agent after the sixth week than in Louisiana. A partial explanation for this may be that, because of the recognized tendency for treated cases to relapse, it became routine in Mississippi early in 1950 before releasing any patient to obtain recheck specimens about 2 months after onset of typhoid fever.

Although not all of the factors involved in the production of a chronic typhoid carrier are known, at least some are reasonably well indicated. These include age, sex, prior gall bladder disease, and the bacterial strain. With a few specific exceptions, for example, Havens and Dehler (22), efforts to analyze large series of typhoid cases have led to the conclusion that both age and sex are important (23, 24). In general, carriers are more common among adults than among children and among women than among men. Frequency of clinically recovered patients who become chronic carriers varies between 2 and 7 percent. The pattern observed in the present series of 1,413 cases is in general agreement with the foregoing analysis. In the group aged 0-19 years, carrier rates of 0.7 to 0.8 percent were observed while in the older age groups rates ranged up to 4.5 percent.

Table 6. Relation of treatment to relapse and death following typhoid fever in Louisiana and Mississippi, 1947-52

Treatment	Number of cases	Relapses		Deaths	
		Number	Per-cent	Number	Per-cent

² Total dose, with course of treatment initiated on or after 15th day of disease.

³ Inadequate total dose regardless of time of initiation of treatment.

⁴ Includes penicillin, sulfonamides, streptomycin, fever pills, and aspirin.

ized, there is some doubt as to the accuracy of the treatment records of such patients. Fortunately, 1,067, or 75.5 percent, of the 1,413 cases under study in the 6-year period, 1947-52, in Louisiana and Mississippi, had been hospitalized. In Louisiana 20 percent more were hospitalized than in Mississippi. These percentages were 82.5 and 62.5 respectively. In both States 638, or 79.9 percent, of the treated patients and 429, or 69.9 percent, of the untreated group were hospitalized.

From table 2 it is evident that of the 1,413 cases included in the study 576, much more than a third, were diagnosed without positive cultures, either blood or fecal, and that positive blood cultures were obtained in only 540 cases, or about 38 percent, of the total. This situation merits some comment and explanation.

During the period of these investigations, I observed repeatedly that, in making a diagnosis of typhoid fever, the practice in many rural areas and in many small private hospitals is to depend only on serologic evidence and clinical symptoms. Fortunately, this applied to only a relatively small part of the study group since many establishments do not admit patients with known or suspected communicable diseases. Many of the cases of typhoid fever in this study were secondary and were picked up

by the local health departments while investigating primary or index cases.

Considering the study group as a whole, it might seem that the relative paucity of bacterial isolations, especially from the blood, could be attributed to the specific antibiotic therapy employed in more than half of the cases. Many investigators have reported that the use of chloramphenicol "sterilizes" the blood and intestinal tract very rapidly. Among these, Woodward and others reported blood sterilization but frequent persistence of the agent in feces and urine after initiation of treatment (14). Supporting these findings are observations of other investigators based on much larger numbers of cases (15, 16). On the other hand, using blood-clot cultures, Thomas and others (17) and Watson (18) report numerous isolations from patients undergoing treatment. The present data, when considered with reference to treatment status (table 2), provide no evidence that chloramphenicol influences the frequency with which positive blood cultures are obtained, as the tabulation below indicates:

Treatment	Percent of patients with positive blood cultures	
	Louisiana	Mississippi
All chloramphenicol-----	35.8	46.0
Nonspecific-----	33.0	43.2

Available evidence indicates that clot cultures are markedly superior to cultures made with whole blood, possibly because the influence of any bloodborne antibiotic and bactericidal serum factors is minimized (19). In spite of the general use of clot cultures, isolations of *S. typhi* from the blood in this series (540 or 56.8 percent of the 950 cases with blood culture attempted) were far less than reported by earlier workers (20, 21). As pointed out in most bacteriology texts, for example, Smith and others (10), frequency of isolations of *S. typhi* from the blood is closely related to the stage of the disease, maximum recoveries being made at the end of the first week. Thereafter, the bacteria disappear from the blood and specific antibodies increase. In this light possibly the more important factor contributing to the lower rate of recovery in this series was the common delay in obtaining the first specimen for culture and serologic tests.

With respect to positive stool cultures the

nosed by isolation of *Salmonella typhi*; 35.8 percent were diagnosed on serologic evidence; and 5.0 percent of the diagnoses were based on epidemiological association plus symptoms compatible with those of typhoid fever.

In both States the highest attack rates were found in the group aged 5-9 years and the lowest in those over 40 years old. In all age groups, the rates were higher among nonwhites and males than among whites and females.

Age and sex are apparently important in the development of the typhoid carrier state. The rate of development of the carrier state in the group under 20 years of age was 0.7 percent as compared with 2.5 percent among the group aged 20 and over, a highly significant increase. Among patients 40 years old and over, 5.2 percent of females but only 2.4 percent of males became carriers.

Although early adequate treatment with chloramphenicol appeared to hasten the termination of excretion of *S. typhi* in many cases, evidence that early treatment acted to prevent the chronic carrier state is weak. The carrier rate for all patients treated with chloramphenicol was 1.0 percent and that of the nonspecifically treated group was 2.0 percent.

The study did provide evidence that early adequate treatment was followed by few relapses and few serious complications. Also, with early adequate treatment case fatality was low (1.9 percent) as compared with that in the nonspecifically treated group (8.1 percent).

Also, in the group over 40 years of age, 5.2 percent of females but only 2.4 percent of males became carriers. In the entire series, the carrier rate was 1.4 percent. Only in one instance was there a history of prior gall bladder disease although 3 of the 20 carriers recognized in this study later had cholecystectomies. Collins and Finland considered the possibility that strain differences may account for the variations in response to treatment with chloramphenicol (25). The belief that only infections with certain phage types result in the chronic carrier state has not been justified by my experience. In this country phage E₁ is the most common type. Of the 6 carriers typed in this study, 2 were E₁. A note of possible interest is that 6 of the 20 newly established carriers in this study lived in the same household with previously known carriers, but only one was related by blood.

In the present study, the crucial question is the possible relation of treatment with chloramphenicol to ultimate evolution of the carrier state. Of the 8 carriers who received chloramphenicol, 4 had been given early adequate treatment and 4 were in the delayed or inadequate treatment group (table 5). Carrier rates for all groups given chloramphenicol and for the group given only nonspecific treatment were 1.0 and 2.0 percent respectively. Although the difference is not significant, it is compatible with the idea that such treatment may reduce the carrier rate to some extent. In support of this idea is the rather clear evidence that in many cases early adequate treatment hastens the time of cessation of excretion of bacteria.

Finally, the study provides data on the relation of treatment to relapse and death. Among the entire group of 1,413 cases there were 165 instances of relapse, or 11.7 percent. These were divided with respect to treatment. Many independent investigators have reported an increasing number of relapses among patients treated with chloramphenicol. Matteucci and others suggest that this evidence would seem to indicate that chloramphenicol therapy of typhoid fever is suppressive rather than curative (26). Smadel and his colleagues in 1949, working in Malaya with a series of 44 patients with typhoid fever, observed a

striking relation between the duration of chloramphenicol treatment and the incidence of relapses (27). They concluded that chloramphenicol should be administered in adequate amounts if relapses are to be avoided. Later Woodward used interrupted treatment in typhoid fever somewhat similar to that used to prevent relapses in the volunteers with scrub typhus (28). He reported no relapses among the eight cases given interrupted treatment.

However, in this study, it is quite possible that the actual percentage of relapses was higher than indicated since some of the patients may have had relapses after discharge from the hospital. These patients were not always followed. Furthermore, relapses were seldom recorded on the epidemiological record for nonhospitalized patients. Dubos states that relapses occur in about 10 percent of the cases and the "mortality rate in typhoid fever is about 10 percent" (29). He also states that in 60 to 75 percent of the fatal cases death is due to the complications of intestinal hemorrhage or perforation. Smadel and others emphasized that chloramphenicol therapy did not eliminate intestinal hemorrhages or intestinal perforation in typhoid (27).

In analyzing the data in this study, it was observed that complications occurred in 38, or 10.2 percent, of the 372 cases treated with 30 grams or more of chloramphenicol, and in 52, or 12.4 percent, of the 418 cases receiving less than 30 grams. In contrast, the control group consisting of 614 cases yielded 188, or 30.6 percent, complications. Some side effects of chloramphenicol were noted, but these were short lived.

Summary

An epidemiological study to investigate the efficacy of chloramphenicol in the prevention of the typhoid carrier state was conducted among 1,413 cases of typhoid fever which occurred during the 6-year period, 1947-52, in Louisiana and Mississippi. The control group comprised 614 cases which occurred largely in the period from 1947-49. In the treated group were 799 cases which occurred during the period 1950-52.

Only 59.2 percent of the cases were diag-

Group Psychiatric Consultation for Nonpsychiatric Workers

THERE is a need to broaden the education of nonpsychiatric professional groups, such as school teachers and nurses, concerning the nature of mental and emotional problems which they encounter in their work and to increase their awareness of relationships between themselves and their pupils or patients. However, the techniques most effective in consulting with these groups may vary somewhat from those with which most psychiatrists are familiar. Therefore, attempts are being made to determine how a psychiatric consultant can be most useful to agencies not specifically concerned with psychiatry, and to their personnel.

A study of the image which public health nurses and school teachers have of themselves within their professional roles indicates that, in order to satisfy their need for a feeling of professional status, they must be given a strengthened sense of the value of their function and an understanding of motivations for behavior which seems to depreciate their role. The close adherence of teachers and nurses to middle-class mores and the anxieties engendered when these are violated require psychological reorientation to many phases of their work.

Consultant's Role

One of the primary functions of a psychiatrist in a health department or school is the inservice training of nurses and teachers in understanding the problems of mental function and dysfunction. An important implicit goal of such a training program is to increase the effectiveness of these workers by reducing their anxieties and distortions in relationships which interfere with objectivity on the job.

In contrast to the group therapist, the consulting psychiatrist must focus on the worker's

relationship to her work problem rather than on the intrapsychic roots of her conflicts. In order to be most effective, he must be able to gauge the degree of self-awareness of a group, and, in working with nonpsychiatric personnel, he must gear the level of discussion to the tolerance of individuals who are often more naive about

Public Health

MONOGRAPH

No. 53

The accompanying summary covers the principal findings presented in Public Health Monograph No. 53, published concurrently with this issue of Public Health Reports. The author is mental health consultant to the Berkeley City Health Department, Berkeley, Calif.

Readers wishing the report in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Mathematics and Science Teaching

Improving the quality of science and mathematics education in the public schools is more important than increasing the number of students taking such courses, a group of prominent educators and scientists have concluded. A summary of their recommendations, *Guidelines for Science and Mathematics*, was issued in May 1958 by the Office of Education, Department of Health, Education, and Welfare.

This statement emphasized that mathematics and science teaching should develop the capacity of boys and girls to think for themselves, as well as communicate facts. Some specific guidelines offered by the group were:

- Students should have the opportunity for continuous experiences with science from kindergarten through high school.
- Science and mathematics should be taught as basic sciences. The teaching of them should impart an understanding of the methods of scientific investigations and research.
- Able students should be offered at least the first year of college work while in high school.
- Continuous training of science and mathematics teachers is required to keep abreast of the changing methods and knowledge.

Additional recommendations concerned curriculum, revision of textbooks, selection of pupils for advanced courses, the use and training of teachers, and other aspects of science and mathematics education.

The guidelines were developed following a conference of educators and scientists held at the Office of Education, Washington, D. C., in February 1958. Its sponsors were the American Association of School Administrators, Council of Chief State School Officers, American Association for the Advancement of Science, National Association of Secondary School Principals, and the Scientific Manpower Commission.

Register of Air Pollution Analyses as of January 1, 1956. *PHS Publication No. 610; 1958; 331 pages; \$1.75.*

A record of community air sampling and analyses performed in continental United States, Alaska, and Hawaii before 1956 is compiled in tabular form. More than 100 chemically definable individual pollutants or constituents of mixed ones, such as dustfall, are listed for 200 cities in 100 counties of 32 States and Territories.

In addition to pollutants, dates, number of sampling stations, length of sampling periods, sampling frequency, sampling equipment, and analytical methods are listed for each survey. The register also gives literature references and addresses of agencies where results of analyses are recorded. An index of pollutants identifies States and cities in which each was collected and analyzed.

Grants and Fellowships. *PHS Publication No. 624; 1958; 311 pages; 75 cents.*

Health research facilities grants, research fellowships, and research grants awarded by the National Institutes of Health, Public Health Service, during fiscal year 1958 are listed separately by State and institution.

An expanded version of a yearly report on research support, this volume contains a list of the advisory bodies responsible for review of research grant applications and a table showing distribution of grants by States and grantee institutions.

Public Health Records and Related Materials. *PHS Publication No. 612; 1958; 108 pages; \$1.*

Selected articles which have appeared in the *Journal of the American Public Health Association* and *Public Health Reports* from 1952 through 1957 have been compiled in this publication. Emphasizing that records cut across program lines and

involve all disciplines, the selections give examples of specific application of principles for improving recording and reporting in public health work.

Among the suggestions offered are a forms control program instituted as agency policy, work simplification, central control of services to individuals and families, and exchange of information between programs.

The Air Over Louisville. *Publication of Jefferson County and the City of Louisville, Ky.; 1958; 57 pages.*

A summary report of an intensive study of air pollution conducted by the Air Pollution Control Board of Jefferson County, the Public Health Service, and other agencies, this booklet describes a 2-year investigation which began in mid-October 1955. A full-scale technical report on the same study is being prepared by the Public Health Service and will be available at a later date.

Copies of both reports may be obtained from Chief, State and Community Services Section, Community Air Pollution Program, Robert A. Taft Sanitary Engineering Center, Cincinnati 26, Ohio.

Public Health and Hospitals in the St. Louis Area. *American Public Health Association Publication; 1957; 414 pages; \$3.75.*

An evaluation of existing services and facilities and specific recommendations to meet current and potential needs are presented in this study. Hospitals and nursing homes, welfare services, rehabilitation, mental health, nursing, dental health, tuberculosis, child health, and health education are covered.

Based on a survey conducted by the American Public Health Association, the appraisal summarizes data gathered from questionnaires, personal interviews, conferences, correspondence, and public hearings.

The Public Health Service, the Children's Bureau, and the Office of Vocational Rehabilitation participated in the study and helped with staff and consultant services.

Copies of the book may be purchased from the Health and Welfare Council of Metropolitan St. Louis, 417 N. 10th Street, St. Louis 1, Mo.

Administrative Medicine. Transactions of the fifth conference, October 29-31, 1956. *Edited by George S. Stevenson, M.D.; Published by the Josiah Macy, Jr. Foundation; 1958; 197 pages; \$3.75.*

Mental health elements in administration of general health programs, the administrative role in the management of a mental hospital, and techniques and devices for communication and cross-fertilization in the coordination of local resources were the topics at the fifth conference on administrative medicine.

With emphasis on discussion rather than formal presentation, the book retains the conversational style of the conference. Questions, criticisms, and comments by participants are recorded.

George St.J. Perrott, former chief, Division of Public Health Methods, Public Health Service, was chairman of the conference, and several other Public Health Service personnel were members or guests. Copies of the transactions may be purchased through a bookdealer or from Josiah Macy, Jr. Foundation Publications, 16 West 46th St., New York 36, N. Y.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

psychological matters than are other professional groups with whom he has had experience in his training and mental health clinic work.

In order to influence the content of group thinking, the psychiatric consultant must help to alleviate the anxieties which impede learning by the worker. The major problem of a consultant to an agency such as a health department is determination of the degree to which he can influence the group's thinking, explicitly by direct discussion of an individual worker's involvement in her case and implicitly by a more generalized handling of the material presented for discussion. While explicit discussion is frequently possible when group morale permits, in most cases anxieties can be allayed implicitly without focusing personally on the worker.

The Berkeley Program

From a study of 117 group sessions with public health nurses during a 4-year inservice training program in the city health department of Berkeley, Calif., theoretical concepts and a formulation of objectives and methods of psychiatric consultation have been developed.

The subjects brought up for discussion in these sessions and the reasons given for presenting them indicate clearly that nurses are primarily concerned with their own functioning and have only a secondary academic interest in the theories and dynamics of emotional disturbance. Their interest in human behavior and motivation is based on a desire to be able to work more effectively with the people whom they encounter in their work and to avoid the anxiety aroused by attitudes on the part of those people which they consider antisocial or rejecting of themselves. The real question behind nearly half the subjects the nurses brought up for discussion, apart from their content, was: How can I change the behavior or motivation of the patient to conform to my standard?

In 80 percent of the cases, the psychiatrist sees the nurses' difficulties as primarily due to emotional reactions interfering with their objectivity. Lack of knowledge, techniques, or interviewing skills sometimes contributes to a nurse's uncertainties, but in the vast majority of cases she can solve her work problem once she sees clearly what is going on between herself and her patient.

WHO Publications

International Standards for Drinking-Water. (1958, 152 pages, \$4.00.) Designed to stimulate further investigations of the problem and immediate consideration of the function of water quality criteria in control and improvement of water treatment and provision of safe and potable water to all people. Among sources used in preparing material were The Bacteriological Examination of Water Supplies, of the Ministries of Health and of Housing and Local Government for England and Wales, and Standard Methods for the Examination of Water, Sewage, and Industrial Wastes, 10th edition, of the American Public Health Association.

Insecticide Resistance in Arthropods. (By A. W. A. Brown, 1958, 240 pages, \$5.00.) Exhaustive account, based on some 625 publications and much unpublished information, of the appearance, history, and geographic distribution of resistance for 40-odd species.

Publications of the World Health Organization, 1947-1957: A bibliography. (1958, 128 pages, \$3.25.) Almost 2,000 items, comprising technical, general, and administrative articles and publications, serially numbered and grouped in alphabetical order by subject, with author and country indexes.

Annual Epidemiological and Vital Statistics, 1955. (1958, 699 pages, \$12.00, bilingual edition: French and English.) Eighth annual volume containing such new data as specific mortality rates, by sex and age, for main sites of malignant neoplasms and distribution of cases of communicable disease by sex and age.

These publications may be obtained in the United States, directly or through a bookseller, from the Columbia University Press, International Documents Service, 2960 Broadway, New York 27, N. Y.

Progress in Medical Research on Air Pollution

HARRY HEIMANN, M.D., L. OTIS EMIK, Ph.D., RICHARD A. PRINDLE, M.D., M.P.H.,
and WILTON M. FISHER, M.D., Ph.D.

For 3 years the Air Pollution Medical Branch of the Division of Special Health Services has been working in the increasingly more important but relatively unexplored field of air pollution in its specific relation to human health. The work began with a search for and a systematic appraisal of the scattered sources of knowledge, followed closely by tentative explorations into those parts of the problem holding promise of significant findings. Sufficiently successful results of initial activities helped chart the present course of action, which, in turn, points toward ideas requiring emphasis in the future.

THE Public Health Service has been concerned with the health aspects of community air pollution for many years (1, 2). It was not until 1955, however, when Public Law 159 was passed by the 84th Congress, that the subject was accepted as of sufficient importance in itself to merit separate study. The Air Pollution Medical Program of the Division of Special Health Services was set up for this purpose in July 1955.

Specifically, the Air Pollution Medical Program was charged with the responsibility of determining whether or not community air pol-

lution modified health among human populations. The first part of this charge involved the problem of definitions. What is meant by community air pollution? What are health effects? What should be the ultimate goal of the program?

For immediate use, air pollutants were defined as those materials in the community air that were contributed by the acts of man, excluding biological agents and radioactive materials (3). It was assumed that a community was an urban aggregation which might well cross political boundaries; it would have a large number of people potentially exposed generally to the same atmospheric air. Health effects were defined as those effects which might result in physiological or pathological changes which could be measured by objective techniques. The ultimate goal was seen early to be the definition of those agents in the air which cause deleterious health effects under specified conditions, so that appropriate steps could be taken to prevent or minimize these effects.

A wide variety of specific information was immediately available. For example, it was known that within the United States mortality rates for certain diseases varied from community to community; that eye irritation in the Los Angeles Basin was associated with the local smog (4); and that those who had died during the acute air pollution episodes of London (5), Donora (6), and the Meuse Valley (7) were generally elderly and frequently had preexisting respiratory or cardiac difficulties. From the same episodes and from other data there was evidence that the breathing of irri-

Dr. Heimann is chief, Operational Research Section; Dr. Emik, chief, Laboratory Investigations; Dr. Prindle, chief, and Dr. Fisher, former chief, Air Pollution Medical Branch, Division of Special Health Services, Public Health Service. This paper is based on a report prepared at the request of the National Advisory Committee on Air Pollution. The report was presented at a meeting of the committee in Cincinnati, Ohio, August 28, 1958.

Diarrheal Disease Control Studies

I. Effect of Fly Control in a High Morbidity Area

By JAMES WATT, Surgeon, and DALE R. LINDSAY, Scientist¹

Common consent for years has ascribed to the fly a major role in the spread of enteric infections. Evidence for this belief was incomplete and did not permit an evaluation of these insects as disseminators of disease. The development in recent years of more potent insecticides, particularly DDT, made it possible to plan and carry out an experiment on a broad scale designed to answer the following questions: (1) Can flies be controlled in urban populations by insecticidal methods under the limitations of action imposed by civilian life? (2) What effect, if any, will such control have on the acute diarrheal diseases of the community, particularly those caused by specific infection with the *Shigella* and *Salmonella* groups of micro-organisms?

The basic needs for such a study were: An area with a significant amount of infectious diarrheal disease; a major fly problem; and geographic location which would permit division of the human population along natural lines into two comparable areas, one to be treated, the other to be left untreated for comparison purposes. This latter condition was essential, since it is known that variations in diarrheal disease rates greater than 100 percent occur from year to year and season to season.

Plan of Study

Such an area was found in the Lower Rio Grande Valley of Texas, and at the request of Dr. George W. Cox, State Health Officer, and the local officials, Hidalgo County was selected as the study area.

¹ From the Division of Infectious Diseases, National Institutes of Health, Bethesda, Maryland, and the Entomology Division, Communicable Disease Center, Atlanta, Georgia.

(1319)

OCTOBER 8, 1948, pp. 1319-1334

In the first controlled study of the role of nonbiting flies in human disease, Dr. James Watt and Dr. Dale R. Lindsay presented evidence on the importance of flies in the transmission of bacillary dysentery.

Those who investigate effects of air pollution on health are in the position of having a large group of potential agents and no specific disease. We suspect that nonspecific effects of air pollution disease now are classed in the catchall of "degenerative disease," or constitute conditions assumed to occur "naturally" in the population. Such conditions would include chronic bronchitis, pulmonary emphysema, and cardiac deaths.

It was necessary to begin our attack upon a broad front and be ready to change direction as information was gained. The pattern of occurrence of chronic bronchitis and lung cancer, on the one hand, and the episodes in Donora and London, on the other, strongly suggested that there were acute effects producing immediate changes in function, even leading to death, and chronic effects demonstrable only after months or years of exposure, or developing long after exposure had ceased. The study of these two phenomena required different approaches with different methods of identifying and quantifying the effects.

Current Developments

Although there is enough evidence to suggest strongly that air pollution can cause many adverse health effects, reliable medical data are not common. Consequently, we have had to search for facts which could withstand careful scrutiny.

The most important known way in which air pollution influences health is that it irritates, and so may possibly damage, membranous surfaces of the body. Our investigations into the recorded acute air pollution episodes show that the primary effects were observed on the respiratory tract with secondary, indirect, effects on the heart. In the Los Angeles area, air pollution appears to have a primary effect upon the eye membranes. The respiratory tract and the eye are particularly susceptible for the obvious reason that they are in contact with the ambient air; and, therefore, these organ systems will receive special attention in this discussion. However, investigations are underway on other matters such as allergy, cancer, and infectious disease. In a field where few guidelines existed we had to create and formulate new tech-

niques on how to measure and evaluate the culpability of air pollution components, how to simulate actual air pollution in test situations, how to measure lung airway resistance, how to employ animal experimental "epidemiology," and how to establish and use air pollution indexes for expressing relative air pollution levels, relative to such elusive factors as intensity, duration, and locale.

Testing of Lung Function

One thing we have needed is a lung function testing method suitable for screening large numbers of people. Through some of our own staff efforts and our support of research at Harvard University, there is now at least one type of testing machine that seems to be suitable for the purpose (16). It indirectly measures the airway resistance to expiration. At the Occupational Health Field Headquarters of the Public Health Service a group is complementing the work being done at Harvard. They are considering how to provide the equipment and personnel suitable for testing a large series of people in their own communities and to determine how such procedures should be applied.

In addition, research at the University of Pittsburgh (17) and at the University of Cincinnati (18) also is concerned with the effects upon lung function of low concentrations of potential irritants. The development of such methods and tests will play an important role in community health studies, such as the current one in Nashville, Tenn. (19). Used in conjunction with information about environmental influences within a community, this type of objective medical examination can add significantly to the usefulness and reliability of epidemiological investigations.

Epidemiological Evaluations

There is also the classic type of straightforward epidemiological investigation in the program. The first such study was a reevaluation of the health of the population of Donora, Pa. (20) in the light of the 1948 air pollution episode (6). Preliminary data indicate that Donora residents who were adversely affected

tants result in changes in respiratory physiology (8-10). There was evidence that ozone was toxic (11-13) and that rather large amounts were in the air of such areas as Los Angeles (14). There was also evidence that oxides of sulfur were present in many urban atmospheres and that they could adversely affect human health. Further, information from Great Britain indicated that observed variations in morbidity and mortality from city to city for some specific diseases were similar in pattern to the known or assumed intensities of air pollution.

A large amount of statistical data offered potentially useful information. But the data needed to be reoriented since they had been compiled for studies or activities unrelated to air pollution. A statistical section was organized in our program to study the application of these data to our purposes.

Two Courses of Action

We pursued two main courses of action. First, studies were designed to measure the health status of a community to determine whether aberrations in health patterns were related to indexes of air pollution. These activities were largely either field investigations or "desk" statistical studies. Second, studies were designed to define the biological or health effects of single or multiple known or suspected constituents of air pollution. These were largely laboratory studies. Thus, the program was divided between epidemiology and laboratory investigations, with certain activities, such as function testing of lungs, falling into both.

For the statistical work we knew that large bodies of data were in the records of vital statistics units throughout the country. Some quick and some more detailed examinations of these data from the viewpoint of specific diseases were essential to see whether any "good leads" were hidden there. Mortality data provide good, solid quantitative figures, but the quality of such data is not as good. For this reason we also needed to examine morbidity records whose accuracy of diagnosis was likely to be of much better quality. The Health Insurance Plan of Greater New York, the Veterans Administration, the Bureau of Old-Age and

Survivors Insurance, and others collect extensive morbidity information. While such mortality and morbidity data were more or less readily available, we found practically no records of air pollution levels to which we might relate them. We had either to develop some kind of index of air pollution that could be applicable to any community or to use the limited data from those few localities where some air pollution measurements had been made. It was decided to do both. Air pollution indexes were developed based upon populations, industry, and fuel consumption for all American metropolitan areas. Detailed, although limited, aerometric information is being used in intracity comparisons. The analyses of these measurements are in process.

Epidemiology of Air Pollution

In the program's general responsibility for defining health problems of communities as they may relate to air pollution, we are employing, insofar as possible, the methods of epidemiology. This method originally was developed and applied to deal with communicable disease. In epidemics, an identifiable disease is present in unusual numbers in a given population. It is a relatively simple matter to divide the community into those who do or do not have the disease. When appropriate information has been gathered to describe the differences between these groups, it then becomes possible to investigate how the disease agent was distributed and how it was propagated. The contribution of the external factors of the environment can be estimated and, in some cases, even defined. More recently, the general utility and applicability of the epidemiological method, with various modifications, has resulted in its broad use in the study of mental disorders, home accidents, automobile accidents, heart disease, and even population control.

An identifiable disease or condition is not always evident in these studies. Only recently research has identified a group of organisms called the orphan viruses because they were not known to be associated with a disease. Surveys have shown that many people carry antibodies for these same viruses. Further investigation revealed the disease (15).

intense urbanization and, by inference, probably with intense air pollution.

To study specific diseases and body reactions believed to be associated with air pollution, the nature of the irritant action must be considered. While ophthalmologists for many years have used irritant materials to stimulate healing of some types of eye ulcers, experimental animals exposed to sublethal levels of ozone (a respiratory tract irritant) have developed pulmonary fibrosis. In both of these reactions, we have examples of the tissue-stimulating properties of certain air pollution components which in one case were beneficial to the organism and in the other harmful.

Nitro-Olefins

Theoretical considerations based on available data have indicated that, under the peculiar circumstances that may at times exist in the air of the Los Angeles Basin, nitro-olefins may be produced in that atmosphere (26, 27). However, the presence of these compounds has thus far not been demonstrated, probably because of their labile nature. Despite this failure, we considered it important to study the noxious properties of the nitro-olefins. In investigations at the University of Miami to test their toxicity, 18 nitro-olefin compounds have proved to be highly damaging to animals, however they are administered (28). With high dosages, deaths occurred so rapidly that only acute congestion of all vital organs was found. When the specific stress factors of high temperature and humidity were added, deaths of the animals occurred even earlier. This confirmed other toxicological studies reporting that biological stress produced in any one of a number of ways, including physical exertion, intensified the effect of poisons (29). So far this investigation at the University of Miami has also confirmed some of the earlier toxicological studies of nitro-olefins. Our investigator at the University of Miami is now ready to begin long-term exposures to nitro-olefins in low concentrations, simulating what, it is believed, may occur in community air.

An adventitious observation was made in the early phases of the study of the nitro-olefins. The researchers found that their own eyes were

strongly irritated when they handled the compounds or even when they examined the animals that had been treated with them. They, therefore, tried the effect of low concentrations on themselves, and found that at levels of air concentrations theoretically approximating those in the air of the Los Angeles Basin they again experienced symptoms of eye irritation (30). These experiments on eye irritation were repeated by an investigator working in Los Angeles, using a different technique; again, it was observed that eye irritation occurred with exposures to low concentrations of the nitro-olefins.

Ozone, Sulfur Oxides, and Aerosols

Other laboratory studies on the mechanism of action of known irritants have been pursued at the Occupational Health Field Headquarters. Most important were those involving ozone, a gas that has its effect in the deeper parts of the lung. Experimental animals exposed to concentrations lower than those previously considered injurious suffered fatal pulmonary edema (31). Animals repeatedly exposed to quite low, safe-concentration levels developed resistance to later exposures known to be toxic (32). It is possible that such a protective mechanism may be of importance in protecting man's lungs from injury under natural conditions. Exploration of the nature of this protective action has not been successful, so far. The phenomenon may be related to the fact that, in the test tube at least, ozone reacts with protein to form a new specific antigenic agent (33). If such a reaction actually occurs between ozone and the surface proteins in the human respiratory tract, it may explain why some resistance to later exposure occurs.

There was one finding already mentioned in another context that was rather disturbing. When animals breathed sublethal concentrations of ozone daily over a period of months, they developed scarring in the lungs (34).

Investigators working on lung-function testing have found that oxides of sulfur (gases produced by burning sulfur contained in small but significant amounts in many fossil fuels) caused increased airway resistance (8). This, it was observed, occurs with air concentrations

during the 1948 episode were more likely to have more illness later than were those who apparently were not affected (20).

The epidemiological survey of the Detroit-Windsor area, a joint venture by the Governments of Canada and the United States, was begun before 1955. From the data seen thus far, we have been able to deduce some methodological ideas (21).

In Nashville (19), mentioned above, we are evaluating health patterns in a community where air pollution, when it occurs, is primarily soft coal smoke. The Nashville study has four broad aspects: (a) a study of mortality by cause and frequency in relation to place and duration of residence; (b) a study from post-mortem examinations of carbonaceous dust accumulations in the lungs, also in relation to place and duration of residence; (c) a household morbidity survey to find out about acute and chronic disease in relation to place and duration of residence, and in relation, of course, to current air pollution measurements; and (d) a study of the influence of measured air pollution upon cardiorespiratory disease patients, including a group with bronchial asthma.

Laboratory and Statistical Studies

Another important approach with bearing on our field of interest is the observation of the effects of airborne irritants upon animals. There often is a high correlation between the effects of an environmental factor upon animals and its effect upon humans.

There are three ways that animals may be used in such investigations. First, wild and domestic animals may be examined for the effects of naturally occurring pollution. The following are cited as two examples of the many reports demonstrating this approach. Informed that the health of chickens was adversely affected by air pollution in the Los Angeles area, we supported a field study of this phenomenon. Because the results were inconclusive, the experiment is now being repeated under well-controlled conditions. Research conducted at the University of Southern California has shown that both the fertility of mice and the survival rate of newborn mice are reduced by long-continued parental exposure to

inhalation of low concentrations of synthetic air pollution of the Los Angeles type (22).

The second way is to expose the animals under experimental conditions to single pollutants or multiple pollutants whose composition is more or less known. Of two such experiments being carried out at Vanderbilt University (23) the first is to determine exactly where in the respiratory tract the common air pollutant, sulfur dioxide, impinges to cause its effect. The second is to observe one series of animals exposed over a lifetime to sulfur dioxide at known low concentrations and another series exposed to bituminous coal smoke.

A third way of using experimental animals is to establish colonies of different species and strains under controlled conditions, and let them live out their lives in typical, urban areas where they would be exposed to the same atmosphere as that breathed by the human inhabitants. Simultaneously, observations would be made of a group of control animals for which the air is appropriately cleaned to remove the pollutants. We are currently financing such a study at Wayne University (24).

In statistical studies, the work is divided broadly into a study of records of past mortality by cause and past morbidity by cause in relation to environmental factors, including, of course, air pollution. At the same time our statistical unit is looking into recent and current frequency of causes of death and the frequency of illness. In both instances efforts have been concentrated on those clinical entities which might be causally related to air pollution.

The first report to come from our statistical unit was Comparative Mortality Among 163 Metropolitan Areas of the United States—102 Causes of Death (25).

The morbidity data for the current retrospective studies were collected from the Veterans Administration records of veterans receiving disability pensions and from records of persons enrolled in the Health Insurance Plan of Greater New York. From such data we have been able to make a preliminary estimate of the possible biological significance of only a small portion. Certain respiratory tract diseases appear to be frequently associated with

indeed be significant. At the University Pittsburgh attempts are underway to test effects of irritant gases upon the lung function of experimental animals in which cardio-respiratory disease has been previously produced artificially (17).

In this connection, a Los Angeles pulmonary physiologist, during periods of high air pollution, has placed patients with known lung disease at the Samaritan Hospital in a special room where only cleaned air is allowed to enter. After a few hours, these people show improvement in the function of the lungs and so in their well-being.

Chronic Bronchitis

In addition to studying the nature of air pollution effects on specific organ systems, the method of evaluating their effects on human health, we hope to observe the relationship of air pollution to specific diseases. At the California State Department of Public Health, investigations currently are underway on the effect of air pollution on the natural history of the diffuse clinical syndrome called chronic bronchitis (43).

Studies of the natural history of chronic bronchitis have been strongly influenced by experience in Great Britain (44). Air pollution in the British Isles, associated primarily with weather and use of relatively low-grade solid fuel, has been a subject of concern for years. The episode in London in December 1952 (5), to which some 4,000 deaths were attributed, led to intensive epidemiological study. Some significant concepts stem from these current investigations.

For some time chronic bronchitis has held a high place among the causes of death in Great Britain (44), certainly much higher than in the United States. Without going into the attempts to consider all the possible variables that may explain the reasons for the difference, it is the consensus of enlightened British medical opinion that they do, in fact, have a high frequency of this disease and that its occurrence is very likely associated with air pollution. In contradistinction to our predicament, they have identified a disease entity which they can relate to their air pollution.

In effective liaison with the British investigators (45), we are currently trying to clarify the reasons for the difference between their frequency of chronic bronchitis and ours. Prevailing judgment among qualified people is that the frequency of this disease in the United States has been increasing in recent years.

Bronchial Asthma

Bronchial asthma has also received considerable attention, but the results of several investigations are far from conclusive. A study in Pasadena, Calif., under the auspices of the California State Department of Health, involved a preliminary survey of the occurrence of asthmatic attacks in relation to certain air pollution variables (46). The results indicated that there was a doubtful association between certain high air pollution levels and occurrence of asthmatic attacks. This finding was unexpected, to say the least. Observations among asthmatic patients in the Nashville study may be useful in clarifying the matter (19).

One of the newest aspects of the Air Pollution Medical Program is designed to investigate the size of the health problem caused by airborne allergens of vegetative and related origins. Seasonal hay fever, it is estimated, attacks between 1 and 2½ million people in the United States; bronchial asthma is said to affect from ½ to 3½ million persons. We are also obtaining data on the degree of disability that these illnesses cause and their cost to the Nation in loss of working ability.

The concept that simple chemical substances may combine with body proteins to form a new substance which may be allergenic has played an important role in establishing our concern with airborne allergens or allergen precursors. Such precursors, simple chemical substances, may well be present in polluted air. We discussed briefly how ozone combined with proteins experimentally resulted in the formation of a new antigenic agent (28). The significance of that observation is enhanced by a report received a few years ago from the U. S. Army in Japan (47). It appeared that in and about Yokohama some persons of the Army of Occupation and members of their families developed symptoms of bronchial asthma on certain days. This was deemed to be due to

found on occasion in some urban communities. It has also been demonstrated that a derivative of sulfur dioxide, sulfur trioxide, in equal concentration is even more irritating than the dioxide (9). Both gases are produced when fossil fuels are burned. Finally, it was shown that the effect of sulfur dioxide, and of certain other irritant gases, is markedly enhanced by the presence of a solid or liquid aerosol which by itself may not be irritating (35). Aerosols of this type, of course, also commonly appear in the air, especially in urban communities. Irritating gases are not all necessarily enhanced by aerosols; the nature of the aerosol itself also is of significance (36, 37). We are currently studying the possible mechanisms of this phenomenon. The thesis that the effect of an irritant gas on the lung is enhanced by the simultaneous presence of an aerosol, however, is not accepted by all investigators, but the preponderance of medical opinion favors it. Since it is impossible to conceive of natural air without the presence of an aerosol of some type, the matter may indeed be significant.

Tissue, Cell, and Enzyme Studies

Necessarily our studies of the action of these noxious agents on the body began at the primary level. Knowing that the body's response to membrane irritation would evoke a series of protective mechanisms that would mask the effect, we determined that one of the better ways to study membrane irritation would be in isolated cells and cell groups. We are promoting such an activity at Baylor University. Using a mixture probably containing nitroolefins as one of the toxicants, data thus far show that such air pollution adversely affects muscle contraction and leucocyte metabolism in special preparations (38). This continuing work has as its ultimate purpose the elucidation of the effect of such air pollutants upon the enzyme systems that are modified to produce these end reactions.

In line with these explorations, we also employed the tissue culture technique which is relatively unexplored for toxicological studies. This technique is applied to the study of cell preparations, generally of human origin, for changes in growth, reproduction, and metab-

olism. An authority in the field of tissue culture studies at the University of Nebraska undertook the project for us. Using tissue cultures about which a great deal is known (fibroblasts, cancerous cervical epithelial cells, and liver cells), the investigator showed that low concentrations of sulfur dioxide stimulate cellular activity; high concentrations of the gas are lethal (39). The effects of sulfur dioxide, nitrogen dioxide, salts of these acid gases, gasoline, and ozone are under continuing investigation.

Work on the causes and nature of eye irritation has progressed slowly. Research in California has produced some significant findings and it is now generally agreed among authorities that although the eyes of susceptible persons in Los Angeles become irritated when certain air pollution constituent levels are high, there are no objective changes in the eyes (40). In addition, the occurrence of eye irritation under experimental conditions is statistically associated with the presence in the air of a group of chemicals that include the nitroolefins, as mentioned (41).

Explorations at the Occupational Health Field Headquarters show that another body system may be affected by irritation from air pollution. While exploring the mechanism involved in the development of pulmonary edema from ozone, previously described, it was shown that there was a simultaneous decrease of certain enzymes including alkaline phosphatase in the affected lung tissue (42). A search was then made for the alkaline phosphatase level in the circulating blood as possibly being a more convenient indicator of lung injury. Again, the enzyme level was found to be altered. In the present state of knowledge we have not been able to extrapolate these findings to the human. But, if we should succeed in doing so, we may be able to detect the degree of lung injury simply by testing a blood sample.

Cardiorespiratory Disease

At the University of Cincinnati, a detailed study of house-bound cardiorespiratory patients revealed that the diffusion of vital gases across the respiratory membranes into the blood was adversely affected by peak levels of urban air pollution in the Cincinnati area (18). This

be acceptable to all, we do keep in mind that there are airborne materials which may act as adjuvants, enhancing the potential injurious effect of even small amounts of such carcinogenic agents. One of these adjuvant factors is the ability of some airborne compounds to remove and thus activate the carcinogenic polycyclic compound sometimes found adhering to an inert particle (60). Similarly, airborne irritants, because they can slow the rate of removal of potential carcinogens from lung airways, enhance the contact time between the carcinogens and susceptible epithelium (61). Finally, airborne irritants cause some denudation of the surface layers of the lining of the air passages, thus exposing the deeper, more susceptible layers to contact with potential carcinogens (62, 63).

Some investigators have shown that airborne irritants, at least those from cigarette smoke, cause appreciable changes in the epithelial lining of the airways of the human lungs (64). These investigators believe that the changes are directly related to cancerous developments. Regardless of whether or not cancer is so related, it is still important that such irritation causes severe changes in the anatomy and in the functional activity of the human air passages.

The air passages naturally get primary attention in considering the relation between air pollution and cancer; but other tissues and organs also may be affected. A preliminary review of our statistical studies on the frequency of cancer of the esophagus and stomach reveals an association similar to that between air pollution and lung cancer. This finding may be related to some experimental observations wherein it was noted that animals exposed to various dusts showed an appreciable amount of dust in the intestinal tract (65). This finding also fits, to a certain extent, the occurrence of symptoms of stomach irritation that occurred in some of the recorded episodes of acute air pollution (6).

In the closing months of 1958, it appears that we can say definitely that several important and significant findings have emerged from our research on air pollution and its effects on man. Although further study is required in virtually all fields, it is obvious that we have uncovered some very promising leads.

Future Emphasis

Analyzing the progress of our program, we have reached the conclusion that during the next few years we can achieve the best results by concentrating research on five principal subjects:

1. The relationship of air pollution to variation in the geographic distribution of death and disease, by cause.
2. The association between air pollution and the functions of the respiratory system.
3. The association between air pollution and cancer and cardiovascular diseases.
4. The effects of specific air pollutants, singly and in combination, in accordance with the varying chemical and physical properties.
5. The fringe areas of air pollution health research.

Locale and Disease

In regard to the first, we have long known that there are important mortality differences among nations, among continents and, to some extent among ethnic groups. Only recently, however, have we begun to appreciate the fact that there are important differences in mortality among cities and that most of the differences may occur even among different areas within a city. There is now no doubt that urbanization exerts an effect on health. The higher the degree of urbanization, the more prevalent do some diseases become. We know, of course, that among the many variables that may contribute to these differences are the following: climate, socioeconomic status, ethnic or genetic composition, food and water supplies, availability of medical care, and the pattern of customs in medical diagnosis. Despite these other variables, however, we are convinced that air pollution is without doubt an important factor among the many potential causes of geographic variations in mortality and morbidity.

We started late in the field of epidemiology because of conceptual and operational difficulties, the necessity to acquire basic statistical data, and the unfulfilled hope that our initial laboratory investigations would provide information and directions that might simplify the human studies. Much of the required demographic data has now been acquired.

material discharged into the air from industrial operations. From the data supplied, the specific causative mechanism is not known. It cannot be ignored, however, that reports of this nature are rare. A few reports in the medical literature (48-50) have directed attention to an allergic response to sulfur dioxide in air; however, it is perplexing that despite the fact that sulfur dioxide is present in the air of so many urban communities, the reports are so rare. If the matter were looked into thoroughly, more reports might be forthcoming.

Respiratory Infections

Although infectious diseases are primarily the concern, in the Public Health Service, of the National Institute of Allergy and Infectious Diseases and of the Communicable Disease Center, our program has been probing the possibility that air pollutants may modify airborne infectious agents; they also may be a factor when exposed human tissue becomes vulnerable to infection. Early studies by others have suggested that airborne chemicals destroy some airborne bacteria and might, therefore, actually reduce the possibility of air-transmitted disease of the respiratory tract. What was not considered in those early studies was the possibility that air pollutants would alter the body membrane surfaces to make them susceptible to infection. A few years ago, researchers at Johns Hopkins University studied the occurrence of pneumonia in mice exposed to coal smoke and then to pneumococci (51). The data indicated that pneumonia did not occur more frequently in mice exposed to smoke. However, another investigator, working at the Armour Research Foundation under Air Force auspices, exposed animals to low concentrations of ozone prior to their exposure to airborne organisms, and found that pneumonia infection was of greater frequency in the exposed animals (52). We are currently supporting research at the University of California on the influence of ozonized gasoline fumes upon the pneumonia rate in mice, exposed also to a virulent pneumococcus (53).

Lung Cancer

The increase in the frequency of lung cancer throughout the world in recent years has stim-

ulated universal interest. The most recent data point to cigarette smoke as a major factor. Cigarette smoking notwithstanding, some statistical studies have shown that the cancer rate is higher in urban areas with high air pollution levels than in rural areas with low air pollution levels (54).

It is generally accepted that the air can carry materials capable of acting as carcinogens. Acceptance of this belief is based in great part on work done with experimental animals. Industrial experience has shown that the air inside certain factories contains some carcinogens. It is not difficult, then, to understand that many of these same agents are released into the community air. Furthermore, such well-known experimental carcinogens as benzpyrene have been found in community air (55), as well as in exhaust gas from the internal combustion engine (56, 57). Research conducted at the University of California at Berkeley has shown that such polycyclic hydrocarbons can be produced by combustion of even some of the simplest straight-chain hydrocarbons under suitable conditions (58).

Some epidemiological investigations of the lung cancer problem in Great Britain show that there is an association between urban living, frequency of lung cancer, and the presence in the air of certain polycyclic hydrocarbons already known to be carcinogenic for experimental animals. Preliminary statistical evaluation of certain American mortality data in our own program bears out the association between air pollution and lung cancer.

Currently in progress, in the second year of a 3-year job, is an investigation of the carcinogenic potential of the particulate matter collected in nine cities in the United States (59). For these nine cities there are relatively wide variations in lung cancer frequency.

Mucosal Changes in Air Passages

In considering the relationship of cancer of the lung (or possibly of other organs) to air pollution, some people deny a possible causal connection between the two because, they say, the amount of potential carcinogenic material in the air is too small to be biologically active. Although we can see no immediate resolution to the controversy on this matter that would

1. There is evidence that death rates for certain causes of death increase markedly with urbanization. Specifically, these causes include cancer of the lung, trachea, and bronchus, cancer of the stomach and esophagus, arteriosclerotic heart disease, and myocardial degeneration. The increase of lung cancer with population density persists even when the degree of cigarette smoking is held constant (54).

2. Fragmentary evidence of the distribution of cancer mortality within cities appears to be at least partially related to the distribution of air pollution intensity.

3. Certain air pollutants found in our cities are known to be experimentally carcinogenic for animals. Chemical analysis has disclosed many other potential carcinogens in air; these may also be carried by particulate matter deep into the lung.

Admittedly, these findings taken together would justify devoting our entire resources to following them up. However, the total air pollution budget of the Public Health Service, slightly less than \$4 million, with about \$1.5 million available for health studies, has powerful allies in the current annual Public Health Service appropriation for heart research (\$46 million), and for cancer (\$75 million). Consequently, the air pollution program is directed to encouraging those with technical and financial resources to undertake epidemiological and laboratory studies on environmental stresses in the community in general, and on air pollution in particular. For example, cooperation with the National Cancer Institute was arranged to determine the carcinogenic potential of air pollution particulate samples collected from nine cities by the National Air Sampling Network. The protocol was developed jointly with the National Cancer Institute and the Air Pollution Engineering Program. The Air Pollution Medical Program paid part of the cost of the first year. The National Cancer Institute assumed the total cost for the second year.

Animal Studies

The fourth subject deals with the effects of different air pollutants. All our previous experience

indicates that the chemical and physical nature of substances are important in determining their biological effects. We have not devoted much effort to studying the effects of specific substances, largely because our air sampling information indicates that, as an acute problem, the community levels found are too low, and that as a long-term problem it is not possible to isolate effects due to one substance from those due to others. We have, however, promoted research work on the effects of mixtures of pollutants and especially those that generally simulate the type of pollution in Los Angeles. Some of the significant leads that stem from those studies are the following:

1. Certain nitro-olefins believed on theoretical grounds to be present in Los Angeles air may be among the factors that irritate eyes. Synthetically prepared nitro-olefins have been found to be highly irritating and rapidly fatal to animals in acute exposures. At concentrations believed possibly extant in Los Angeles air at times, they cause eye irritation in man.

2. There is diminished oxygen uptake and decreased growth of micro-organisms exposed to simulated Los Angeles type of air pollution.

3. The fertility of experimental mice and the survival rate of newborn mice seem to be reduced by the artificial Los Angeles type of air pollution.

The Los Angeles area has made great strides in controlling its original sources of air pollution. The most important remaining uncontrolled source of pollution in Los Angeles is said to be the internal combustion engine. Because of special budgetary considerations we expect to be able to expend a large sum during the next fiscal year on the study of automobile exhaust gases and their toxicity. These studies will be based in part upon a research facility that will generate, monitor, and analyze various types of light-irradiated exhaust gases and will then feed them to exposure chambers designed to study the effects on vegetation, micro-organisms, and small experimental animals.

Fringe Areas of Research

Our fifth subject, the fringe areas, includes those problems which appear to be of primary concern to researchers who are not in air pol-

What are the principal results thus far of our epidemiological studies, preliminary though they may be?

1. There is evidence that the people who were affected by the air pollution episode in Donora in 1948 have more sickness and a higher mortality rate later than their fellow townsmen of similar ages who were not affected.

2. There is evidence that death rates for certain causes increase directly with degrees of urbanization. Specifically, these causes include cancer of the lung, cancer of the stomach and esophagus, and arteriosclerotic heart disease and certain other heart conditions.

3. Short-term increases in air pollution exposures cause changes in the lung function of persons with chronic cardiorespiratory impairments, and this effect may be delayed for 3 or 4 days after exposure. Exposure to "filtered air" may relieve these symptoms.

Admittedly, these findings are not as definitive or comprehensive as we would like them to be. We feel, however, that they are sufficient to justify the more intensive studies now underway, and those planned for the next few years. This means that we shall continue direct operational support of statistical analysis of morbidity and mortality data, community surveys (such as those at Nashville and Donora), and morbidity investigations similar to those on chronic bronchitis and bronchial asthma in California.

Irritants and Breathing

The second major subject has to do with the effect of air pollution on man's breathing ability. The effects found thus far are essentially those resulting from irritation. The important findings include the following:

1. Irritant gases, such as sulfur dioxide and ozone in amounts similar to those in community air, have an adverse effect upon man's ability to breathe.

2. Continuous or repeated inhalation of ozone scars the lung tissues of animals.

3. Exposure to ozone disturbs the alkaline phosphatase levels in the body, which may indicate that other changes in enzyme and metabolic activity are occurring.

4. Irritant gases cause pulmonary edema and

affect enzyme systems and other physiological mechanisms.

5. Inhalation of some irritant gases mixed with certain aerosols that are usually considered physiologically inert increases the adverse effects of the gases.

6. On the other hand, repeated inhalation of small quantities of ozone, and possibly other gases, appears to result in a significant degree of increased resistance to the acute effects of ensuing heavier exposures.

These findings have resulted in the main from experimental exposures of animals. Their extension to human beings poses obvious difficulties of varying degrees, and in a few instances, efforts of such extension have already begun. We expect to continue to support and carry out the significant leads by the following: (a) evaluating pulmonary function; (b) continuing research grants in basic and applied pulmonary physiology; (c) direct investigations of effects on animals exposed to irritant pollutants; and (d) research contracts to groups using basic and applied physiological techniques. Although the basic laboratory work involving biochemistry, enzymes, and tissue cultures has shown promise, the findings can not yet be extended to man. Because of the basic nature of this research it is best supported by the research grant mechanism.

Cancer and Heart Disease

Our third major subject includes lung cancer, and possibly other cancers, as well as cardiovascular diseases.

No one can deny that heart disease and cancer are two of the important diseases in this country today. Together, they account for 54 percent of all deaths (66). Lung cancer, although accounting for only 1.8 percent of deaths (66) has been increasing rapidly in recent decades. Statistical studies relate this increase in lung cancer to cigarette smoking. A similar association has been shown with heart disease mortality, which, although less startling in percentages, is even more impressive in total numbers of deaths. What light, if any, have studies on air pollution thrown upon the causes of these diseases?

lution work. One example is that of the inhalational allergies. This subject is divisible into two aspects. First, the familiar plant pollens, causing hay fever and similar reactions. Second, the question of whether or not chemical conditions in air can cause allergic reactions in some susceptible people.

Another example in this fringe area is the effects of air pollutants which reach the gastrointestinal tract. If our pilot studies of such questions indicate the serious possibility of important findings, we are prepared to follow through.

Long-Range Goals

We have described a blueprint for the near future. These are the things we are doing now or will be doing during the next 2 or 3 years. Medical research in air pollution from the long-range aspect, we believe, will be the following:

First, we think we shall some day return to the consideration of effects upon cells and tissues. Methods will eventually be developed whereby we will be able to extrapolate the observed effects to intact animals and to human beings. Controlled exposures of isolated cells and of tissues will then be a screening device.

Second, we expect that we shall develop realistic maximal permissible concentrations, based on reliable studies and adaptable to the industrial and meteorological conditions of a given city.

Third, we think that the public health engineer and the public health physician will participate much more in studies of community ecology, in planning and zoning programs, and the like. The advantages and disadvantages of alternative proposals may be evaluated, not only in aesthetic and economic terms, but with reference to present and future effects upon the health of the community.

New Laws Affecting Health Activities

The following legislation affecting health was passed by the 85th Congress during its second session:

P. L. 85-544 authorizes the Surgeon General of the Public Health Service, for fiscal years 1959 and 1960, to make training grants totaling \$1 million annually to schools of public health (H. R. 11414).

P. L. 85-664 extends the Hospital Survey and Construction Act for 5 years (H. R. 12628).

P. L. 85-589 amends the Hospital Survey and Construction Act to permit applicants to obtain loans in place of grants for the construction of hospitals and related facilities (H. R. 12694).

P. L. 85-777 extends for 3 years the Health Research Facilities Act, which authorizes \$30 million annually for research construction grants (H. R. 12876).

P. L. 85-840, among other Social Security Act amendments, increases by \$5 million each the annual appropriation authorizations for three State grant programs administered by the Children's Bureau: maternal and child health, crippled children, and child welfare (H. R. 13549).

P. L. 85-908 provides for White House Conference on Aging in 1961 and authorizes Federal financial aid for preparatory State conferences (H. R. 9822).

P. L. 85-926 provides for grants of up to \$1 million to institutions of higher learning to expand educational opportunities for *mentally retarded* children through teacher training and other programs (H. R. 13840).

P. L. 85-929 amends the Food, Drug, and Cosmetic Act to prohibit chemical additives in food that have not been pretested for safety (H. R. 13254).

in a wide range of areas. Surprisingly, lack of funds was given as the major reason for not expanding chronic disease laboratory services. Lack of space and lack of trained personnel were listed as other obstacles.

If funds and personnel were available, 15 States indicated they would undertake blood sugar determinations, 14 would do Papanicolaou smears, 13 would do blood grouping, and 9 would start blood chemistry. Many other types of testing would be initiated in other States.

In a supplementary inquiry, the Division of Special Health Services, Public Health Service, recently polled the State health department laboratories again, using regional office staffs to gather the data.

We were interested mainly in learning the extent to which some of the basic tests were being performed by State laboratories. The results corroborated the earlier findings. A great deal of valuable work is being done along these lines.

No fewer than 19 States reported blood sugar testing: 9 of these were engaged in screening; 5 in routine quantitative testing; and 5 reported use of the clinitron.

Nine States test for blood cholesterol.

Twelve have programs for examining Papanicolaou smears.

Five do rheumatic fever (antistreptolysin titer) testing.

Two test for rheumatoid arthritis.

A variety of other tests are being performed by one or more States, including, of course, blood grouping, blood typing, and urine analyses.

Although it appears that a significant amount of chronic disease testing is performed by many State health department laboratories, we must face the fact that 20 States reported no testing of any kind for noninfectious diseases. I believe that this picture will change. It is bound to.

New Tests and Machines

Several exciting new tests and possibly even more exciting new machines are now being used by testing laboratories.

The Papanicolaou smear is not a new test,

but its application in large-scale casefinding programs is relatively new. Recognition by the public health and medical professions of the great possibilities of the cytological test for cervical cancer is truly exciting. This simple, usable, and teachable test has brought one important phase of cancer prevention within the range of classic public health and preventive medical practice. The laboratory has made this possible.

Another exciting cancer advance is perhaps foreshadowed by the work of Dr. Claude Hitchcock of the University of Minnesota, who reports that screening for low acid content or absence of acid in the stomach is an effective means of diagnosing gastric cancer in the asymptomatic phase.

Screening 12,000 men and women over a 10½-year period, Dr. Hitchcock found the incidence of cancer 4½ times greater among patients with no acid or a low acid content of the stomach. He recommends annual gastrointestinal X-ray examination for the latter group and an examination every 9 months for the former group.

In the bentonite flocculation test, a type of colloidal clay (bentonite) is mixed with normal human gamma globulin. When the test is positive the clumping or flocculation of the mixture can be seen under a microscope in a few minutes. This test was positive 85 percent of the time when used on 82 verified cases of rheumatoid arthritis at the National Institutes of Health.

A new approach to the prevention of rheumatic fever is heralded by a testing process employing a fluorescent dye to "tag" serum antibodies. (See *Public Health Reports*, October 1958, p. 884.) This method, if it proves applicable, promises to be fast and simple. Positive results may be reported on slides containing only 200 bacteria. Conventional tests require as many as 100 million organisms, the culturing of which may take a week or more. Most laboratory technicians can perform the fluorescent dye tag test, given the training and equipment.

Never in the 70-year history of public health laboratories in this country has the development of new laboratory tests moved at so rapid a pace as during the last decade. Fresh progress is reported monthly.

The Chronic Disease Laboratory in Public Health

ALBERT L. CHAPMAN, M.D.

IN A TIME when the triumphs of technology have literally made real many of man's most fanciful dreams, I may be pardoned if I venture some bold ideas about the future of laboratory work in public health.

I honestly believe that we shall live to see the time when laboratory tests will penetrate the mysteries of the chronic diseases. I believe that, ultimately, laboratories will be able to identify most, if not all, of the leading chronic diseases through simple, valid tests that will be economical to perform.

For example, the "fingerprints in the blood" which we are only beginning to understand may eventually reveal through the analysis of a single blood sample the presence or absence of a whole array of chronic conditions. Most important, such future testing can detect the presence or even the threat of a chronic disease in ample time to heed the warning.

Medical science, by its conquest of the infectious diseases, has not ended an era. Rather, it has opened an even greater era, which will be known in history for victories won over the chronic diseases. And, as in years gone by, laboratories again will be the shock troops in the attack that has now commenced.

Some 70 years ago, a small room in the Marine Hospital on Staten Island, N. Y., was set aside as the first Public Health Service laboratory. It wasn't long before States set up similar laboratories all over the country. These laboratories have been landmarks in the progress of

the modern public health movement in the United States.

Epidemiology, the central discipline of public health, cannot exist without the laboratory, any more than the automotive industry can exist without highways.

No reminder is necessary of the amazing progress in laboratory testing in recent decades. Progress has been equally notable in pathology, biochemistry, toxicology, bacteriology, mycology, parasitology, and serology.

In an effort to determine the extent to which State public health laboratories had expanded into the chronic disease field, the American Public Health Association's Committee on Laboratory Services in the Chronic Diseases sent out a questionnaire in 1957 to State laboratory directors.

Having been granted the privilege of quoting from the interim report based on that questionnaire, may I first commend one of its introductory statements:

"Since the chronic diseases fall for the most part in that category of illnesses . . . in which secondary levels of prevention, such as early diagnosis and treatment are important, it seems obvious that the laboratory should have a place in their control."

In connection with this philosophy, a most important finding of the questionnaire is that 20 out of 32 State laboratory directors who responded believed in the need for providing chronic disease services in their laboratories. Only 7 of those reporting did not so believe.

The interim report shows that 11 State laboratories are now performing a significant number of tests in the chronic disease field in addition to blood grouping or blood typing.

Certain States (Maryland and Wisconsin are discussed in the interim report) are already engaged in large-scale chronic disease testing

Dr. Chapman, an Assistant Surgeon General, is chief of the Division of Special Health Services, Public Health Service. This article has been adapted from an address by Dr. Chapman at a meeting of the Western Branch, American Public Health Association in British Columbia, Canada, on May 20, 1958.

MAN and Environment

CONFERENCE REPORT

To examine research needs in the modern environment, the National Institutes of Health, upon the recommendation of its Study Section on Sanitary Engineering and Occupational Health, called the Conference on Man and Environment in Washington, D. C., May 5-6, 1958. The following pages carry information from six of the papers presented.

To mention only a few of the testing machines, machines that are as exciting as the new tests themselves, the great utility of the Papanicolaou smear may now be enhanced tremendously by an electronic machine called the cytoanalyzer. This device supplements the technician in the microscopic search for malignant cells. Abnormal cells are counted electronically on the basis of structural characteristics. The cytoanalyzer, when perfected, has the potentiality of screening thousands of slides daily. Seldom has an invention more perfectly fitted the needs of casefinding.

For blood analysis, among several new machines introduced on an experimental basis is the autoanalyzer which performs, through the use of automatic colorimetric analysis, routine determinations of urea, sugar in blood, and calcium in serum. The results of the analysis of the blood sample, indicating the concentration of certain substances in the blood, are permanently recorded every 90 seconds, permitting 40 determinations an hour.

Disease "Fashions" and the Laboratory

Laboratory practices reflect the current "fashion" of prevailing disease. Today, blood is being fractionated and the characteristics of these fractions are being determined by many new methods: spectroscopy, electrophoresis, and paper chromatography. A whole new armamentarium of disease detection is slowly but steadily being developed.

During the early decades of the 20th century when such diseases as smallpox, malaria, diphtheria, pneumonia, typhoid fever, tuberculosis, dysentery, and the communicable diseases of childhood were the primary threat to life, laboratory practices reflected the logistical importance of these diseases.

With the aging of our population and the relative increase in incidence and importance of the chronic noninfectious diseases, laboratory practices are slowly but steadily beginning to reflect the growing importance of these currently more "popular" diseases.

There has been a significant lag in the widespread use of available tests for noninfectious diseases, few as they are, partially because of difficulties in retraining professional and other laboratory personnel in new methods of laboratory analysis. Some of the lag can be attributed also to the belief that public health laboratories should not become involved in tests for noninfectious diseases; and some of it has been caused by the scarcity of precise and economical tests.

But much of the lag, in my opinion, can be traced to inadequate funds and inadequate staffing of public health laboratories. These inadequacies, of course, are attributable in large part to the lack of appreciation of the value of laboratory procedures in the early detection, diagnosis, and control of the chronic, noninfectious diseases, and the lack of public and professional support for expansion of these activities.

When mass chest X-ray programs were first introduced, the demands for the services of private radiologists increased because of the many new cases of treatable tuberculosis that were found. I am confident that this phenomenon will be repeated when adequate methods and facilities are developed and put into widespread use to insure the early detection of unsuspected cancer, diabetes, heart disease, and arthritis. In fact it seems that the importance and stature of clinical pathologists will rise in direct proportion to the expansion in the number of laboratory tests that are done on apparently well persons for the purpose of identifying asymptomatic diseases.

The battle against these noninfectious killers is a common battle. The private physician and the clinical pathologist are fitted to lead and direct the various campaigns against them. Public health physicians and their staffs and the directors of State and local health department laboratories and their staffs are in a position to give invaluable assistance to private physicians and clinical pathologists so that the efforts of all of the professional groups concerned may be effectively coordinated. Through their joint action, the public is bound to benefit.

what has resulted from the profound changes wrought in the industrial environment by modern technology.

Why are we not more deeply concerned about what has been happening to us during the last half century within the revolutionized environment of our daily work? The time has come when we must carry out physiological and hygienic research hand-in-hand with technological research and when we must develop the techniques of industrial hygiene stepwise with the technology of production.

Health in an Industrial Society

If we are concerned about our industrial population, we also should be concerned about our population generally, for the industrial environment has become, to a remarkable extent, the national environment. This environment which man has created for himself now provides the challenge to both curative and preventive medicine, a challenge that requires additional types of medical knowledge, new medical skills, and new settings.

What of the artificial situation in which many new materials, possessing infinite possibilities for metabolic modification, find their way into the body of man? Is it not evident that our attempts to detect signs of the early or late injurious effects which may follow the absorption of these materials over a period of years or a lifetime are somewhat crude and even naive?

We shall never be able to anticipate and visualize the harmful potentialities of new materials until we achieve a comprehensive understanding of the role of the normal elements and other components of the living organism. Within such a comprehensive background, however, we could probably discover metabolic deviations induced by chemicals now within the organic milieu.

No principle of biology is clearer than that which relates a physiological response to a quantity of stimulus within appropriate time limits. The living organism is resistant in varying degree to varying stimuli, and the stimulus must be adequate to induce a response. Upon this principle we differentiate between harmful and harmless stimuli. In these terms, toxicity relates not to a specific substance but

to the concentration of a substance within certain time limits in the tissue or chemical system of an organism. A toxic environment, therefore, is one which, within certain time limits, introduces a harmful quantity of a substance into the organism.

In modern times the changes man has wrought through his technology have brought about greater environmental changes of more profound physiological significance than have all the previous generations of men. The time has come, however, when a much greater and more comprehensive knowledge of the consequences of our changed and changing environment is essential for our safety and perhaps for our very survival.

Technology has created a wealth of materials and captured the forces of nature for man's use, but it has failed to bring an understanding of their biological effects that will keep these forces and materials under control. The gap between technology and biology must be reduced before it is too late. It must become an axiom of modern chemical and technological research that the materials produced and the energy harnessed must be as well understood for their biological potentialities as for their physical and mechanical properties.

Reckless man can release or build up physical forces which may destroy himself and his kind. Probably, however, the same ingenuity which has enabled him to explore and to penetrate other secrets of nature will serve him when he expends it in learning more of his own vulnerability and in developing the means for self-protection.

Water Supply

 Our research needs may be stated simply: to augment supplies of water by novel means, to reduce water loss, and to treat polluted water for re-use.

By 1975 the use of converted sea water to augment the water supply in coastal cities may

Based on a paper by Mark D. Hollis, Assistant Surgeon General and chief sanitary engineering officer of the Public Health Service.

The Modern Environment

brief

It is not necessary to study vital statistics to perceive some of the more glaring hazards of modern life. Yet the severity of these hazards cannot be viewed in proper proportions without quantitative information. Many departures from an earlier way of life have occurred within the past two generations, and thus the vital statistics of any earlier time and the mechanisms for their collection are hopelessly inadequate.

We are aware, however, of a heavy toll of deaths and injuries on the highways and in the homes; of accidental poisonings, especially among children, so numerous as to require regional and local poison centers for the prompt transmission of information and advice; of public apprehension concerning the functions of airborne carcinogenic agents, whether from the partial combustion of petroleum or tobacco, in inducing or contributing to the induction of lung cancer; of heated controversies over the treatment of community water supplies; and of the contamination of foodstuffs with insecticides and other foreign substances. And we contemplate with great uneasiness the dispersion in the air and the deposition on the land and in the sea of increasing quantities of radioactive substances. These are on the horizon of the average citizen.

Certain other features of the modern environment appear to have graver significance in their capacity for present and future harm. Never before has man at work been surrounded by so many obvious as well as insidious dangers to health, limb, organic integrity, and life itself.

By the study of accidents and illness we learn the causes of injury, disease, and death. But what are the consequences, throughout a working life, of the almost daily impact of individual and collective insults of minor or subclinical severity? Those with more complacency than curiosity, with more faith in physiological adaptability than can be justified

by medical evidence, and with undue comfort derived from crude statistics will respond that the people in no previous society have been known to die young in such small numbers and to live to be old in such large numbers. The easy conclusion is that Americans are healthier now than ever before and that modern life holds no very serious threat to health. But consider the facts less superficially.

Changing Statistics

The microbiological era of medicine and public health has profoundly changed the practice of medicine, has brought into existence and cultivated the techniques of preventive medicine, sanitary engineering, and public health, and has made revolutionary changes in the statistics of human morbidity and mortality. The microbiological diseases, almost to the exclusion of all others, have occupied the attention of the medical practitioner, the investigator, and the educator for more than 50 years. Only recently, compelled by the changes in the causes of illness and death, has attention begun to shift proportionately to chronic degenerative diseases.

Meanwhile the environment of the Nation's population has been changing. The microbiological threats to human life and health have been replaced by the inanimate threat of the machines and materials which inventive man has made, and by the forms of energy with which he has surrounded himself. The physical basis of modern industry is something new under the sun—an environment which, in the making, has taken so much of man's total time, effort, thought, and ingenuity as to leave him little to expend on learning what might be its ultimate effects upon himself.

Not only is the incidence of occupational disease unknown because suitable mechanisms for reporting and assembling information are lacking, but great areas of industry are not under such observation as would provide this information. It is by no means certain, therefore, that the effects of the composite hazards of industry have not affected the national health since, in our gross morbidity and mortality statistics, the brilliant results of microbiological prophylaxis and therapy may have masked these effects. We do not know, and we have no present means of knowing, just

Based on a paper by Robert A. Kehoe, M.D., director, department of preventive medicine and industrial health, University of Cincinnati, Cincinnati, Ohio.

generation, in spite of knowledge that the conventional rapid sand filter is less effective than properly controlled chemical coagulation in turbidity removal and less reliable than breakpoint chlorination for micro-organisms.

The assessment of the public health aspects of viruses in the water environment requires improved methods for recovery and identification of viruses, especially in the treatment of water. Also the transmission of infectious hepatitis virus through contaminated water emphasizes the need to develop a tissue culture technique for the growth of this virus.

These are some basic problems of water supply. Should we concede that the routine identification of unknown substances, inert or organic or viable, in water is too difficult? Because of this difficulty, would it be practicable to require the polluter to purify waste completely? Are we giving sufficient attention to the possible adverse cumulative effects of foreign materials in drinking water?

Or, in view of the level of health in our metropolitan areas, are we magnifying unduly our water supply problems? Our concern about some of this is admittedly potential and based on lack of data, especially of the toxicological implications.

For the immediate future, professional judgment will have to be applied to these issues. But the supporting data, through research, should be sought as promptly as is feasible.

Water Pollution

brief The impact of the development of modern metropolitan areas is of great significance in man's environment.

The total population growth of the United States has not only been high but has been taking place almost entirely in the Nation's 174 metropolitan areas, which the Bureau of the Census defines as areas containing at least 50,000 persons with population densities, by counties, exceeding 150 persons per square mile.

The 16,000 units of governments and 3,000

Based on a paper by Ralph E. Fuhrman, executive secretary, Federation of Sewage and Industrial Wastes Associations, Washington, D. C.

special districts within these metropolitan areas give a measure of the complexities of administration in such tasks as the collection and disposal of waste water used by their inhabitants. A recent book, *Special District Governments in the United States*, decries the multiplicity of these units, and its author, J. C. Bollens, concludes that special districts are justified for schools but feels that other activities should be returned to local governments.

If a sanitary engineer surveyed the collection and disposal of waste water in metropolitan complexes, he would certainly conclude that special districts are justified for sanitary engineering activities as well as for schools. The fact that the metropolitan area is being used more and more in providing for waste water disposal would seem to justify them.

Perhaps a study of this approach could either assure its continuation or point the way for improved and more economical approaches to water pollution control in metropolitan areas. Such a project would have important economic as well as engineering aspects.

Odor control in sewers, pumping stations, and treatment plants is a definite need in waste water treatment. Fundamental work on odor-causing compounds and odor intensity measurement was done at Harvard University more than 25 years ago. Since that time much has been written about sources of odors and how these may be controlled through cleanliness in the plant and chemical treatment.

While cleanliness is essential, the fullest control of odors has been achieved at the Owl's Head plant in New York City through plant housing with exhaust gases discharged through a stack after treatment with ozone. A circular trickling filter at Sarasota, Fla., uses plastic covering on an aluminum frame for a filter cover. Research in odor control could be a re-evaluation and extension of the work at Harvard. Experience to date seems to indicate that the most reliable control is the housing of plant units and treatment of the exhaust air. Basic information on the economy of various designs would be helpful.

Further research in higher degrees of waste water treatment could also be done. At present a 90 percent removal of B.O.D. is looked upon as "complete" treatment. However, satisfac-

be feasible and perhaps routine. Novel methods under study offer promise that the ocean may be effectively and economically tapped. At present full-scale plants can distill sea water at a cost of \$1.75 to \$2.80 per 1,000 gallons. The goal is \$0.30 per 1,000 gallons.

While present weather modification techniques may be crude and ineffective, we must accept them as a potential means of increasing the supply of water. The President's Advisory Committee on Weather Control concluded that cloud seeding produced an average increase in precipitation of 10 to 15 percent in mountainous areas of the western United States.

A substantial part of our future water needs may be met by conservation of flood waters, control of losses through evaporation, recharge of aquifers, and the use of hexadecanol in monomolecular layers on water surfaces.

A 10-foot stratum of sandy soil of average porosity underlying a watershed will hold the greatest single flood flow likely to occur on that watershed. Although we now have no way to use water-bearing strata effectively in flood containment and water conservation, more intelligent use can be made of underground reservoirs to supplement surface storage.

Water lost by evaporation in the United States exceeds the amount taken for use in cities and towns. It has been estimated that evaporation from storage units now under construction in the Colorado River system will equal more than one-third of the replacement storage they provide. Research on the use of monomolecular films of long-chain fatty alcohols to suppress evaporation, however, supports optimism concerning the ultimate ability to reduce evaporation by nearly one-half.

Reclaiming Water

Water supply research, however, must concentrate on new processes to reclaim water. Reuse of water is complicated by the growing number of contaminants in solution. The treated drinking water of a community contains an intricate mosaic of stable organic chemical structures which reflect the past history of the supply. To this burden of chemicals, the community adds its increment of solids, including soluble, persistent, nonoxidizable compounds

like the alky-benzyl-sulfonate component of detergents. The Nation's use of detergents, 3 billion pounds per year in 1956, is expected to double within the next decade.

Drainage from land treated with insecticides, weedicides, and other materials adds to the load of persistent organics now being recovered from all parts of the main stem of the Mississippi River. DDT, in a concentration of 5 ppb, was recovered from Lake St. Clair on the Canadian boundary. The Department of Agriculture's large-scale imported fire ant control operations in the southeastern States eventually will apply dieldrin and heptachlor to some 30 million acres. The United States' production of pesticides and other organic agricultural chemicals rose from 125 million pounds in 1947 to 570 million pounds in 1956.

Management of impoundments, including municipal water reservoirs, for recreational use is also influencing the character of drinking water.

Conventional yardsticks of pollution, B.O.D. (biochemical oxygen demand) and coliforms, give few clues to the presence of these synthetic organic pollutants. Advanced studies on adsorption may indicate useful supplementary treatment for municipal water supplies. Methods for separating dissolved solids from water also are being investigated in connection with desalination.

The toxicological significance of organic chemicals in drinking water has not yet been adequately evaluated. Because of the high cost of toxicological evaluation, a short-time, presumptive test to determine the chronic toxicity potential of specific or complex materials is required.

Particulates and Viruses

Concern with dissolved contaminants does not detract from the familiar problem of particulates. One of the most surprising findings in the recent Chanute, Kans., study was the large amount of organic debris of particle sizes up to 20 microns appearing in the filtered water. This observation supports the opinion that a critical review of filter design criteria is in order. These criteria have not been changed in any important respect in the last

to ban by fiat either of these two classes of reactants. It is my opinion that the practical form of control of such reaction products will prove to be a selective elimination of those species of primary compounds determined to dominate the identified chain reactions.

Sulfur Compounds and Aerosols

Still missing is considerable information about what happens to sulfur compounds in photochemically activated atmospheric systems. Prof. H. Fraser Johnstone and associates are contributing valuable experimental evidence of the rate of formation of SO_3 from SO_2 in the presence of moisture and catalytic particles, and Dr. Mary Amdur has produced evidence of enhancement of SO_2 toxicity by the presence of NaCl aerosols of small average particle size. But there are numerous theoretically possible interactions among SO_2 and the assorted organic and inorganic free radicals believed to form in polluted air during irradiation.

Dr. Amdur's work has also shown the possibility that some species of aerosols influence the toxicity of some kinds of gaseous pollutants. Another function of aerosols, suggested theoretically and supported by the experiments of Prof. Jack G. Calvert and associates at Ohio State University, is the possibility that specific kinds of airborne particles act catalytically to a significant degree in the photochemical system.

Effects of Specific Pollutants

Prolonged dosages at low levels of concentration of highly reactive oxidants, free radicals, and condensation products of the photochemical reactions of organic compounds are strongly suspect in various chronic and acute diseases of the respiratory system. Which are culpable, if any? At what levels of concentration do they cease to be troublesome over long periods of exposure? Do they produce or predispose to carcinomas of the lung and other sites? Does long exposure to any of them at some level of concentration affect longevity, work efficiency, or general well-being? Do any of them, specifically or in combination with other circumstances, affect respiratory or

other restrictive systematic impairments? All these questions need to be answered.

Analysis

For a long time in the future, the tools available will limit the understanding of atmospheric reactions and their products, the effective monitoring of pollutant levels, and useful pollution surveys. Instrumentation and analytical methods for air pollution work need to be inexpensive, simple, direct, and specific in principle and in operation. New and cheaper methods for establishing patterns of pollution movement in all three dimensions of the air reservoir will be essential for regional zone planning.

It is reasonably suspected that, of the numerous measurements habitually incorporated into air pollution surveys, only 1 or 2 give information fully as useful as that obtained by collecting all the measurements in any given local situation. One of the most pressing immediate needs is the provision of bases for selecting 1, 2, or 3 simple, direct indexes of pollution related to identifiable patterns of pollution sources.

These subjects for research could certainly be extended into the engineering control of sources of pollution. As technological changes occur in manufacturing processes, transportation, and commerce, a continual procession of new abatement techniques will be demanded and developed.

The Next 50 Years

Much less certain, however, are the major air pollution concerns of the next half century. The following suggestions are based on a few indications of what seems destined to affect the air supply or improve our capability for cleansing it.

Pollution by radioactive chemicals. A considerable body of opinion insists that the airborne products of nuclear fission and fusion processes are endangering the health of present and future generations. Nothing foreseeable will prevent the continued exploitation of atomic energy for peaceful or military purposes. Inevitably, local and worldwide prob-

tory disposal of treated hydrowastes will become more necessary in future years because the volume of wastes to be treated will increase and the volume of a receiving stream will remain constant.

With the processes now established, stabilization ponds or intermittent sand filters may be relied upon to reduce B.O.D. residuals to 5 percent or less. But devising processes practicable where the large areas required for these methods are not available would aid the reclamation of water for re-use for purposes other than drinking or cooking.

It is important to watch continually the publication of research reports. Unpublished research work remains hidden from most other researchers. For this reason, all research, whether or not it appears productive, should be reported at its conclusion so that the wasted effort and money to repeat it can be avoided. As a minimum step, condensations of lengthy reports or theses should be offered for publication in the technical press.

Re-use of Water

brief The most important research needed in water pollution is in the reclamation and re-utilization of waste waters. Acute shortages of fresh water, long a problem in the arid west, are beginning to plague areas of the midwest, east, and south as the demand for water skyrockets. Man's greatest impact on his water resources is his increased demand for fresh water and his reckless pollution and abandonment of once-used water.

Among the consequences demanding new or improved knowledge are:

- The survival rates and destruction mechanisms for all types of pathogens in various treatment processes.

- The calculated risk in health hazards and other detrimental effects associated with use of waste waters for irrigation, recreation, stock

watering, and perhaps for human consumption

- Mechanisms for the removal or inactivation of sulfates, nitrates, and phosphates, especially in waste waters being used for ground-water recharge.

- The modifications of polluted water as it flows through porous media of varied geochemical composition, and, conversely, the effect of such water upon soil structures.

- Systems analysis in the water balance of an area.

Air Pollution

brief The following listing of the present problems of air pollution is a composite of the convictions of a number of informed people. It is probably significant that each one suggested essentially the same listing, although there was no general agreement on the relative importance of the items.

Chemistry of Air Pollution Systems

Substances causing eye irritation, accumulations of ozone, damage to vegetation, and possible physiological damage in man appear to be labile, transitory constituents of an ever-changing system and therefore have proved difficult to measure or identify. Their existence appears to depend on the photochemical formation of free radicals, if indeed certain types of free radicals are not responsible for the observed and suspected effects. Since the existence of free radicals is essentially co-terminous with the activating solar energy, capture and analysis apart from the continuously activated system have not been accomplished or seriously attempted.

Of course, the primary reactants involved in the chains of reaction can be recognized; in Los Angeles the elimination of oxides of nitrogen and of organic vapors, especially the unsaturated compounds, would effectively inhibit the formation of the suspected labile intermediate compounds. But it has proved difficult

Based on a paper by J. E. McKee, professor of sanitary engineering, division of engineering, California Institute of Technology, Pasadena.

to ban by fiat either of these two classes of reactants. It is my opinion that the practical form of control of such reaction products will prove to be a selective elimination of those species of primary compounds determined to dominate the identified chain reactions.

Sulfur Compounds and Aerosols

Still missing is considerable information about what happens to sulfur compounds in photochemically activated atmospheric systems. Prof. H. Fraser Johnstone and associates are contributing valuable experimental evidence of the rate of formation of SO_3 from SO_2 in the presence of moisture and catalytic particles, and Dr. Mary Amdur has produced evidence of enhancement of SO_2 toxicity by the presence of NaCl aerosols of small average particle size. But there are numerous theoretically possible interactions among SO_2 and the assorted organic and inorganic free radicals believed to form in polluted air during irradiation.

Dr. Amdur's work has also shown the possibility that some species of aerosols influence the toxicity of some kinds of gaseous pollutants. Another function of aerosols, suggested theoretically and supported by the experiments of Prof. Jack G. Calvert and associates at Ohio State University, is the possibility that specific kinds of airborne particles act catalytically to a significant degree in the photochemical system.

Effects of Specific Pollutants

Prolonged dosages at low levels of concentration of highly reactive oxidants, free radicals, and condensation products of the photochemical reactions of organic compounds are strongly suspect in various chronic and acute diseases of the respiratory system. Which are culpable, if any? At what levels of concentration do they cease to be troublesome over long periods of exposure? Do they produce or predispose to carcinomas of the lung and other sites? Does long exposure to any of them at some level of concentration affect longevity, work efficiency, or general well-being? Do any of them, specifically or in combination with other circumstances, affect respiratory or

other restrictive systematic impairments? All these questions need to be answered.

Analysis

For a long time in the future, the tools available will limit the understanding of atmospheric reactions and their products, the effective monitoring of pollutant levels, and useful pollution surveys. Instrumentation and analytical methods for air pollution work need to be inexpensive, simple, direct, and specific in principle and in operation. New and cheaper methods for establishing patterns of pollution movement in all three dimensions of the air reservoir will be essential for regional zone planning.

It is reasonably suspected that, of the numerous measurements habitually incorporated into air pollution surveys, only 1 or 2 give information fully as useful as that obtained by collecting all the measurements in any given local situation. One of the most pressing immediate needs is the provision of bases for selecting 1, 2, or 3 simple, direct indexes of pollution related to identifiable patterns of pollution sources.

These subjects for research could certainly be extended into the engineering control of sources of pollution. As technological changes occur in manufacturing processes, transportation, and commerce, a continual procession of new abatement techniques will be demanded and developed.

The Next 50 Years

Much less certain, however, are the major air pollution concerns of the next half century. The following suggestions are based on a few indications of what seems destined to affect the air supply or improve our capability for cleansing it.

Pollution by radioactive chemicals. A considerable body of opinion insists that the airborne products of nuclear fission and fusion processes are endangering the health of present and future generations. Nothing foreseeable will prevent the continued exploitation of atomic energy for peaceful or military purposes. Inevitably, local and worldwide prob-

lems of pollution by radioactive byproducts will increase in frequency and intensity.

Meteorological control of local air pollution. Significant strides toward long-range weather prediction have been made during the past 20 years, and some progress toward local modifications of meteorological phenomena has been reported. Our imminent capability for satellite observation of air movements and the availability of nuclear energy makes it worthwhile to consider modifications of regional meteorology to assure more adequate air movement.

Effect of air pollution on world climate. Some evidence has been advanced that combustion processes are adding CO₂ to the atmosphere so rapidly as to cause accumulation in spite of the water reservoirs with which this gas must be in equilibrium. A significant change in CO₂ level in the air could, in theory, produce profound effects on world climate. Worldwide monitoring of CO₂ concentrations, an International Geophysical Year project, might well be continued.

Jurisdiction in air pollution control. Many of these situations imply the extension of air pollution study and control beyond local, State, and national jurisdictions. Already a need has appeared in a few regions to establish acceptable procedural and survey patterns that will permit authorities to act jointly. Preparation for concerted action among governments will be essential to effective application of technological principles.

The problems we face are increasing in some exponential relationship to national and world populations. Almost all the environmental factors demanding attention are of two kinds: those involving competition for finite amounts of the materials required for human existence, and those resulting from the accumulation of byproducts of the human utilization of such substances.

Thus air, water, and basic nutritional, industrial, transport, and energy requirements become the foci of efforts to maintain health, reasonable living standards, and some comfort in the face of an exploding population. Sooner or later health agencies will have to face the fact that 600 million people cannot live well in the waste products of resources capable of sustaining half that number.

Food Technology

brief

Food processing and distribution is about an \$80 billion industry, the largest in this country. Concomitant with the industry's growth there has emerged a need for further information about the effects of processing upon food.

The food processor today is well aware that he must consider the factors of color, flavor, texture, convenience, stability, aesthetics, nutrition, and safety, all of which influence consumer acceptance.

To maintain or obtain the desired color it is at times necessary to use particular processes or chemicals. Fundamental work on natural colors and the various processing treatments influencing them is greatly needed. Intensive studies are being conducted on the nature of flavor and the effects of various processes and storage conditions.

In recent years convenience has received more attention than any single factor in the processing of foods. In many foods convenience has dictated the use of a great variety of chemicals and new processing techniques and the mixing of various food components. A large amount of work remains to be done on the stability, safety and nutritional properties of these products.

Other Consumer Influences

Stability, or shelf life, is extremely important in all foods, for practically none are imperishable under adverse temperature conditions. Deteriorative changes resulting in loss of flavor, color, texture, and nutritive value occur very commonly during storage. At State food conferences being held to encourage better nutrition, much is said about variety in the diet and proper nourishment, but nothing is heard about storage deterioration and its possible effect on nutrition.

These deteriorative changes may also be important from the standpoint of safety. There is some evidence that the chemical products re-

Based on a paper by Emil M. Mrak, chairman, department of food technology, University of California, Davis.

sulting from such changes can be harmful and some may affect appetite. The need for research in food stability during storage is apparent.

The aesthetic values of foods are a major consideration. While insect contamination is probably not harmful, it is repugnant and chemical fumigants are used to control it. There should be sufficient data to support the view that these fumigants are safe.

The nutritional value of foods is of prime importance. Consumers generally believe that fresh products are far superior to canned, frozen, or dried foods, yet we know that fresh products can deteriorate very rapidly in acceptability and nutritive value. Because of improper harvesting, distribution, and handling of fresh foods, I would not be surprised to find that, on the whole, processed foods have better vitamin retention than the fresh.

Food processors must be careful about chemical residues, insect fragments, and other such items in their products, but relatively little attention is given to these in marketing fresh produce. There is a need for extensive studies on the acceptability, nutrition values, and general quality of fresh produce.

Changes in Processing

Great changes are taking place in canning procedures. The so-called short high-temperature procedure is receiving more consideration because of a possibility of increasing case yields, faster operation, and better color and flavor. However its relationship to storage stability, nutritional value, and acceptability of the produce is not completely known.

The rapidly increasing rate of production of frozen foods, particularly precooked or partially cooked dishes, makes it improbable that an adequate study has been made of the changes in microflora that occur during this type of processing.

Concentration of foods by the use of a vacuum at relatively low temperatures is now a common

processing procedure. However, a great deal is yet to be learned about its effect on enzymes, chemical changes, microbial survival, and vitamin retention.

Circumstantial evidence indicates that food-borne infections are fairly common, but to my knowledge the amount of work being done to investigate them is limited. How extensive is salmonellosis? Are staphylococcus infections increasing? Would not a thorough understanding of the causes of these infections and the development of control procedures be better than prescribing drugs after infections?

Today most of our foods are packaged. The Food and Drug Administration insists that safe materials be used in packaging; nevertheless we need to know how these materials may affect food.

The food industries are mechanizing as rapidly as possible even though the effects of mechanization on acceptance, nutritive values, and storage characteristics are not completely understood. For example, the bulk handling of cling peaches from the farm to the consumer is almost a reality, yet we do not know the results such handling will have on the fruit. Last year transporting peaches in water in plastic containers was tried. Those in the containers for 6 hours had a low acceptability because of off flavors.

If we are to give the consumer canned peaches that are perfectly safe, with highest vitamin content and best color and flavor, it is important to know what happens between the orchard or processing plant and the consumer. Quite possibly some treatment during processing may adversely influence storage of the product, causing a loss in nutritional value or color or even the production of compounds resulting from deterioration.

Food should be considered from the time the seed is planted, the egg is laid, or the animal born, until it is consumed. So much can happen to food as it passes through various stages, and any one factor may so markedly affect it, that nothing can be overlooked.

lems of pollution by radioactive byproducts will increase in frequency and intensity.

Meteorological control of local air pollution. Significant strides toward long-range weather prediction have been made during the past 20 years, and some progress toward local modifications of meteorological phenomena has been reported. Our imminent capability for satellite observation of air movements and the availability of nuclear energy makes it worthwhile to consider modifications of regional meteorology to assure more adequate air movement.

Effect of air pollution on world climate. Some evidence has been advanced that combustion processes are adding CO_2 to the atmosphere so rapidly as to cause accumulation in spite of the water reservoirs with which this gas must be in equilibrium. A significant change in CO_2 level in the air could, in theory, produce profound effects on world climate. Worldwide monitoring of CO_2 concentrations, an International Geophysical Year project, might well be continued.

Jurisdiction in air pollution control. Many of these situations imply the extension of air pollution study and control beyond local, State, and national jurisdictions. Already a need has appeared in a few regions to establish acceptable procedural and survey patterns that will permit authorities to act jointly. Preparation for concerted action among governments will be essential to effective application of technological principles.

The problems we face are increasing in some exponential relationship to national and world populations. Almost all the environmental factors demanding attention are of two kinds: those involving competition for finite amounts of the materials required for human existence, and those resulting from the accumulation of byproducts of the human utilization of such substances.

Thus air, water, and basic nutritional, industrial, transport, and energy requirements become the foci of efforts to maintain health, reasonable living standards, and some comfort in the face of an exploding population. Sooner or later health agencies will have to face the fact that 600 million people cannot live well in the waste products of resources capable of sustaining half that number.

Food Technology

Australia for the first isolation of antibiotic-resistant strains in hospital populations, the development of bacteriophage typing as a new tool in staphylococcal research, and for the first demonstrations of the epidemiological patterns of hospital-acquired staphylococcal disease.

"The Symposium on Staphylococcal Infections sponsored by the New York Academy of Sciences in February 1956 brought together for the first time in this country much of the existing knowledge of the twin problem of antimicrobial resistance and staphylococcal infections in hospitals. Shortly thereafter, epidemiological studies began to appear, showing not only the nationwide prevalence of resistant strains in hospital populations, but the spread of such hospital-acquired infections into local communities.

"Since then, concern has mounted in research, clinical, and public health circles. In October 1957, for example, the Association of State and Territorial Health Officers recommended that the Public Health Service seek funds to expand its technical assistance to the States on staphylococcal problems.

"In December, the American Hospital Association, through its Council on Professional Practice, appointed a Committee on Infections Within Hospitals. This committee consulted with the Joint Commission on Accreditation of Hospitals and with the Public Health Service concerning staphylococcal infections and in May 1958 issued a bulletin recommending action in hospitals and local communities. Earlier in the year, the American Academy on Pediatrics, through its Committee on the Foetus and the Newborn, issued a supplement to its standards for the management of premature and newborn nurseries, calling for special attention to staphylococcal infections.

"For the current fiscal year, Congress appropriated \$325,000 to the Public Health Service for the Communicable Disease Center's laboratory services, training, investigations, and epidemic aid in staphylococcal disease, and added \$1 million to our research appropriations for the expansion of staphylococcal research through National Institutes of Health research grants.

"Last April, I asked the American Hospital Association's Committee . . . to advise me on

New Agents Counter Staphylococcus

Two antibiotics were reported to be apparently effective against staphylococcal strains, at the Sixth Annual Symposium on Antibiotics, October 1958 in Washington, D. C. In 2 years of clinical trials of vancomycin, no resistant staphylococcus bacteria were encountered, according to Dr. M. M. Kirby and two colleagues of the University of Washington. They added that in 30 patients who were administered the drug in the last year results were dramatic in instances where other antibiotics had failed.

Another antibiotic, kanamycin, was presented as a highly effective bactericidal agent with a broad spectrum by researchers at the University of California and Wadsworth Veterans Administration Hospital. They described its use on 100 patients.

Also, Dr. Paul A. Bunn and Dr. Aldona Baltch of the State University of New York Upstate Medical School report in the *New England Journal of Medicine*, October 2, 1958, that kanamycin has been found "to have an inhibiting action against most staphylococci that are penicillin-resistant" in the treatment of 25 severe and acute infections in the adult.

this problem of national action. What are the immediate needs? And how can the Public Health Service best help to meet them? These consultants agreed that:

"First, knowledge of the existing problem of staphylococcal disease and the means for its control needs to be consolidated and brought home to the medical and health professions at all levels as quickly and as impressively as possible. A national conference should be called to develop a practical plan and to stimulate State and local action.

"Second, a complete review and careful expansion of staphylococcal research should be undertaken. In this area of need, the National Institutes of Health has been busy.

"The third need expressed by my consultants was for expansion of services to assist hospitals in preventing and controlling staphylococcal disease. This cannot be done, we all know, without high-quality bacteriological and epidemiological services and very few hospitals have such services intramurally. Laboratory

The National Conference

on

Staphylococcal Disease

THE NATIONAL CONFERENCE on Hospital-Acquired Staphylococcal Disease was held in Atlanta, Ga., September 15 to 17, 1958, under the joint sponsorship of the Public Health Service and the National Academy of Sciences-National Research Council.

The conference brought together delegates from 59 professional organizations and specialists from universities, independent laboratories, and hospitals.

In the opening address, Dr. Leroy E. Burney, Surgeon General of the Public Health Service, underscored heavily the importance of blocking hospital-acquired staphylococcal disease from invading the public environment. The threat, he said, "involves the development of antibiotic resistance and emergence of specific epi-

demic strains, with the concurrent threat to hospital populations and the community at large."

Other highlights of his address follow:

"Staphylococcal disease has rarely presented itself in modern times as a public health problem requiring an organized community attack, and not until now as a problem of national significance and growing magnitude. Only recently have the several professions involved in medical, hospital, and public health services begun to understand the dynamics of staphylococcal disease and hence to recognize our dependence upon one another for its control.

"We in the United States . . . must give the palm to our medical and public health colleagues in the United Kingdom, Canada, and

officer should be invited to be a consultant to the committee.

Responsibilities

The hospital infections committee should have the following major areas of responsibility:

Surveillance. The committee should regularly collect complete data on all infections acquired within the hospital, on those occurring among recently discharged patients, and determine the presence of a problem, if one exists. These data should be consolidated into formal reports for submission to the medical staff and the hospital administrator.

Control. The committee should be charged with the responsibility of evaluating all phases of hospital operations pertaining to the control of infections, recommending changes, establishing appropriate patterns of antibiotic usage, and instituting epidemic control measures.

Nevertheless, this committee should in no way relieve the department heads of responsibility for making decisions and executing recommendations with reference to particular department problems.

Education. The committee should sponsor an educational program for all hospital personnel, presenting current concepts in the proper prevention and control of hospital-acquired infections.

It is recognized that the effectiveness of any system for dealing with hospital-acquired infections will depend upon a continuing, active program directed to all professional and nonprofessional groups.

Mechanisms of Operation

Mechanisms of operation will vary considerably in the individual institutions. Frequent and regular meetings of the committee are essential to maintain a high level of interest. One of the measures of effectiveness of the committee will be the thoroughness with which advice is implemented into action. Determination of the effectiveness of the committee should rest primarily with the committee and the medical staff, and not with possible inspecting agencies.

Ample emphasis should be placed on surveillance, since the major defect in delineating the staphylococcal

problem is the lack of uniformity in recognizing and reporting staphylococcal disease. Of the several methods of surveillance considered at this conference, routine culturing of all infections received the most support. In applying this method, culture results are routinely reported to the hospital infections committee for investigation, review, and classification. The final classification of each case should include the committee's determination as to whether or not the infection was acquired in the hospital. Surveillance of this type may be facilitated by the utilization of a standardized reporting form.

INTERHOSPITAL

Because patients acquiring infections in one hospital may subsequently be admitted to another and because of the frequent interchange of personnel among hospitals, interhospital communications are essential to infections control. Such communications might be developed by establishing infections committees in the local medical societies, with representatives from the hospitals in the area. Interhospital communication might also be achieved by the addition of members of the staffs of other hospitals to the membership of the hospital infections committee.

HEALTH DEPARTMENT

The health department can be of considerable help to the hospital in controlling infections by providing laboratory services, epidemiological consultation, and assistance with surveys of illness among discharged patients. To attain optimal communications between hospitals and health departments, the health officer should be made a consultant to the hospital infections committee.

OFFICIAL REPORTING

Official reporting of staphylococcal diseases is difficult because of the ubiquity of minor community-acquired staphylococcal infections. No specific recommendation concerning voluntary or compulsory reporting of staphylococcal diseases is made. Some delegates felt, however, that mandatory reporting of staphylo-

coccal disease during the first 6 weeks of life might be helpful. Diseases in this age group to be reported might include pyoderma, breast abscess, empyema, and osteomyelitis. Other conferees feel that it is feasible to report all staphylococcal infections provided the reporting forms are simple. In some States, staphylococcal disease is now notifiable. The reporting programs of these States warrant careful evaluation.

Patient Care

ADMISSION POLICY

It is known that some patients are more susceptible to staphylococcal disease than others. Since hospitals may represent a significant reservoir of staphylococcal infections, individual hospitals should reconsider their admission policies regarding highly susceptible patients. In many instances, these patients might be better managed in the home.

Patients with staphylococcal disease requiring hospitalization should be recognized as a potential danger and proper precautions instituted at the time of admission.

ISOLATION

Infected patients are a major source of hospital infections. Ideally, all infected patients should be placed in strict isolation. This ideal is often unattainable. Priority then should be given to isolating those who are most likely to spread infection to others; for example, patients with pulmonary staphylococcal infections or with exposed foci of suppuration. In addition, it is advisable to isolate certain patients who are especially susceptible to staphylococcal infections, such as those with extensive burns or exfoliative dermatitis.

The transportation of patients with staphylococcal infections from one area of the hospital to another, while often necessary, may be dangerous. It is recommended that these patients be covered with sterile sheets during transport. Careful cleaning and disinfection of the areas in which they have been examined or treated should be a routine procedure.

identification of staphylococci, epidemiological consultation, epidemic aid, nursing consultation, and other services such as are common in State health departments—and through them, in the Public Health Service—will be needed in increasing volume as more hospitals begin to explore and control their staphylococcus problem.

"In this area, of course, the Communicable Disease Center is the Public Health Service's right arm. Staphylococcal disease has been given the highest priority throughout the Center. The laboratory, for example, has accepted responsibility for the National Reference Center for Staphylococcus Phage Typing. Diagnostic reagents are being prepared on a large scale by the Communicable Disease Center. Also, its Epidemic Intelligence Service physicians and nurses have been working full time on epidemiological studies in response to increasing requests for help. Training courses for laboratory workers are being developed and a wide variety of new training aids are being prepared. We expect that all of these services will be expanded rapidly as the national program gains momentum."

As the conference progressed, the participants scanned all facets of the hospital-acquired disease. They took inventory of current knowledge by presenting papers during general sessions, and by open discussion in three small groups, assigned respectively to nursery, surgical, and general medical activities in the hospital. Finally, the delegates framed a set of recommendations which Dr. Burney hoped would be "accepted as 'marching orders' for every group concerned with sick and healthy people in this campaign against staphylococcal disease."

Appearing in this issue of *Public Health Reports* are the conference recommendations, Dr. Harry F. Dowling's résumé, and a paper on the community aspects of hospital-acquired staphylococcus infection by Dr. Frederick H. Wentworth and associates. Dr. R. E. O. Williams' report on the staphylococcus situation in Great Britain appeared in the November 1958 issue, p. 961.

The full proceedings of the conference were published in October 1958 by the Communicable Disease Center for distribution to hospitals, medical societies, and health departments.

Synthesis of Recommendations

General Recommendations

The conference accepts hospital-acquired staphylococcal disease as a serious problem of global scope. There are major difficulties in comparing the incidence of infections now being observed with that in previous years, but it is generally accepted that convincing evidence establishes the problem as a serious one and that definite action on the part of hospitals and other community agencies is imperative.

Communications

INFECTIONS COMMITTEES

It is unanimously agreed that the establishment of hospital infectious committees is a sound approach to the recognition, prevention, and con-

trol of hospital-acquired staphylococcal disease. The conference endorsed the recommendations of the American Hospital Association and the Joint Commission on the Accreditation of Hospitals. The following recommendations concerning the composition, responsibilities, and mechanisms of operation of such committees deserve special emphasis.

Composition

The hospital infections committee should consist of active, interested members of all major hospital departments, including administrative, clinical, nursing, housekeeping, and laboratory. The committee must have complete administrative back-

ing. The chairman or coordinator of the committee must be a person of stature. It is generally agreed that the bacteriology laboratory is the area through which most information about infections should be channeled. It is recommended that a bacteriologist, pathologist, or clinician with interest in bacteriology, be a permanent member of the committee and that he or some individual be charged with maintaining the day-to-day record of infection. This person should serve as hospital epidemiologist.

It is recognized that the composition and size of the committee will vary considerably from hospital to hospital, depending upon their physical and personnel resources. The committee should make free use of small subcommittees of key people for specific assignments. It is also recommended that the local health

sheets, blankets, and mattresses may play a role in the spread of infection, and thus deserve special attention.

Patients admitted to the hospital should be furnished with clean blankets, sterilized linens, and clean mattresses. Cleanliness of mattresses may be approached through the use of disposable or nondisposable plastic covers.

STERILIZATION

Because sterile technique is so fundamental to the prevention of hospital-acquired staphylococcal disease, techniques of sterilization and disinfection require constant attention and reevaluation. Meticulous checks, both thermal and bacteriological, on the effectiveness of ordinary methods of sterilization should be routinely carried out. The need for sterilization of certain kinds of equipment, such as stethoscopes, ophthalmoscopes, and sphygmomanometers, should be reconsidered.

Personnel Carriers

Carriers of staphylococci among hospital personnel present one of the more difficult problems in the control of hospital-acquired staphylococcal infections. There are really two problems here. The first is the individual with a frank lesion, the other is the inapparent carrier who is without overt lesions.

FRANK INFECTIONS

It is strongly recommended that hospital personnel, including physicians, nurses, and others, who develop frank staphylococcal lesions should be excluded from duty until the lesions are healed. It is further recommended that:

- A continuous program of education of all personnel emphasize the hazard of staphylococcus lesions to the welfare of the patient.
- Personnel be required to report the presence of lesions to a central clinic or to a designated physician.
- All reported lesions receive prompt diagnosis and therapy.
- A policy be adopted to prevent financial loss to personnel who are barred from duty because of frank lesions.
- During an epidemic or period of

increased incidence of staphylococcal disease, active search be made for the presence of lesions among the personnel. Such a program can be appropriately directed by the infectious committee. In searching for carriers, a thorough physical inspection should be made to detect those who may have hidden but dangerous lesions; for example, in the axilla, buttocks, and perineal region.

THE INAPPARENT CARRIER

The majority of hospital personnel may be shown at one time or another to be carrying coagulase-positive staphylococci on their skin or mucous membranes. It must be stressed that most of these carriers are not hazardous to the patients, because they either disseminate very few staphylococci or the particular strain of organism which they are carrying is of low transmissibility or pathogenicity, or both. The mere presence of coagulase-positive staphylococci, therefore, is not grounds for removal of a carrier nor does it constitute an indication for antibiotic therapy. Thus, routine surveillance for carriers is not recommended.

During an epidemic or increased incidence of disease, it is essential that a thorough search of all personnel be made for carriers of epidemic strains associated with the

outbreak. The usually accepted method for finding carriers is restricted to nasal or nasopharyngeal culture surveys of the personnel. In instances where carriers of epidemic strains are not found by this technique, it might be helpful to extend the examination of personnel to other potential portals of exit, such as the hair, throat, perianal skin, and stool.

Carriers of epidemic strains associated with the outbreak should be considered "dangerous carriers" and should be removed from duty. Many carriers, even the temporarily dangerous ones, will cease to carry the epidemic strain upon their removal from the contaminated environment. The status of the individual carrier must, therefore, be periodically evaluated and after his reversion to negative, he should be returned to duty.

When an epidemic strain persists in a carrier, his permanent removal from duty must be given careful consideration. Such victims should receive assistance in the form of new job training.

Many substances such as antibiotic nasal jellies and sprays have been used both for the prophylaxis and for local treatment of carriers. The conference is unable to recommend any of these procedures at the present time but urges their evaluation.

Specific Recommendations

In addition to those recommendations which apply generally to the detection and control of hospital-acquired staphylococcal disease within the hospital, the conference has made certain recommendations which apply specifically to a particular service within the hospital.

Nursery

DISCHARGED INFANTS

It is characteristic of staphylococcal disease in newborn nurseries that the vast majority of infants do not develop lesions until after they have been discharged from the hospital. In order that the hospital may become aware of a staphylococcal problem within the nursery as early as

possible, some method needs to be devised for detection of infections among the discharged infants. Several methods have been used for this purpose: telephone surveys, questionnaire surveys, routine visits by public health nurses, or culture surveys of infants at the time of discharge. The conference generally recommends the telephone survey as being most desirable in epidemic situations because of its efficiency, promptness, and ease of administration. However, all of the methods enumerated have been shown to be effective in some communities, and the hospital infections committee should decide which one to use after consultation with other community

It is becoming increasingly apparent that techniques of isolation have fallen into disuse and are unfamiliar to both professional and nonprofessional personnel. Consequently, as practiced, they are often ineffective. It is strongly recommended that the hospital infections committee carry out continuing programs of education in isolation procedures. (See the section on hospital sanitation for recommendations on sterilization, disinfection, and hospital design).

DIAGNOSIS AND THERAPY

Certain techniques formerly considered minor, such as venipuncture, intravenous cannulation, clisis, catheterization of the urinary bladder, and aspirations of body cavities, indeed all procedures which interrupt the normal skin barrier, may produce important portals of entry for staphylococcus infections. It is recommended that these procedures should be kept to a sensible minimum and always be performed with strict asepsis.

The conference considered both the general problems of antibiotic therapy within the hospital and the application of antibiotic prophylaxis to the control of infections.

General Antibiotic Usage

There was unanimous condemnation of the indiscriminate use of antibiotics and acceptance of the need for plans to govern their judicious usage. No single plan has yet been found to be satisfactory for application in all types of hospitals and therefore specific recommendations cannot be made. It is urged, however, that hospital infections committees give priority to a study of this problem and design an orderly approach to meet their own needs.

Antibiotic Prophylaxis

With certain exceptions, antibiotic prophylaxis to prevent staphylococcal infections has not proved to be a useful or desirable procedure, and it is not recommended.

One exception to this recommendation may be made in the nursery epidemic situation where antimicrobial prophylaxis against the specific epidemic strain may be the method of choice for the interruption

of an epidemic (see Specific Recommendations, Nursery). Other exceptions may be made for certain types of patients who are at special risk. In these cases, antibiotics should be used only after careful deliberation by a group or committee concerned with the problem.

It is unanimously agreed that prophylactic antibiotics do not prevent staphylococcal infections in clean surgical wounds, but that they may tend to mask or attenuate the appearance of the infections. It should be emphasized that the most important points in surgical wound management, whether the wounds are operative or traumatic, are asepsis and meticulous, careful technique, combined with the removal of all devitalized and contaminative foreign material, and closure of tissues with maintenance of an adequate blood supply.

Hospital Sanitation

The widespread occurrence and hardy nature of the staphylococcus stimulated considerable discussion of the importance of high standards of environmental sanitation. The recommendations are grouped into those concerning hospital design, ventilation, housekeeping procedures, and sterilization and disinfection.

HOSPITAL DESIGN

Basic to the effective application of aseptic technique is the provision of proper equipment and space allocation for their implementation. Certain deficiencies in hospital design are becoming apparent, but because present knowledge does not permit definitive recommendations about changes in hospital architecture, caution must be exercised before undertaking extensive building alterations in the hope that they might limit staphylococcal disease within hospitals.

On the other hand, it is recommended that hospital administrators seriously consider such alterations as are necessary to bring existing facilities up to standards currently recommended by the American Academy of Pediatrics, the American Hospital Association, and State and local health departments.

In addition, scientifically controlled research studies should be conducted to determine, for example, the optimal design for newborn nurseries and to demonstrate the validity of minimum standards currently recommended for the elimination and control of cross-infection.

HOSPITAL VENTILATION

Cognizance was taken of the many studies describing a reduction of the concentration of bacteria in the environment following the installation of various types of ventilation equipment. It is agreed, however, that these methods have not been adequately evaluated in terms of their specific effect upon the prevention of infection. No recommendations concerning changes in existing ventilating systems were made, but it was suggested that proper cleansing and maintenance of air conditioning systems now in operation should be a routine hospital housekeeping procedure.

HOUSEKEEPING PROCEDURES

There is growing evidence that poor housekeeping techniques contribute to the dissemination of hospital-acquired staphylococcal infections. It is agreed that effective housekeeping demands constant vigilance on the part of both the administrative and professional staff and can be effectively accomplished only when all groups give due recognition to this aspect of disease control. It is recommended that the hospital infections committee periodically evaluate all parts of the housekeeping routine, giving special attention to adequate dust control, acceptable techniques of floor cleaning, sterilization of equipment, and laundry procedures.

As recent studies have focused attention on the laundry and its role in the dissemination of infection, it is recommended that great care be given to insure that contaminated linen and blankets, particularly from patients with staphylococcal disease, not be mixed with other laundry, that contaminated trucks not be used for transporting clean laundry, and that clean and dirty laundry never be transported concurrently. Evidence suggests that

ices, they are essential to the detection of sources of nursery epidemics and their control; and are helpful in the control of outbreaks or in other services. However, it is strongly recommended that hospital laboratories adopt some systematic method of saving isolates of staphylococci from infected individuals, so that in

the eventuality of an outbreak, it will be possible through bacteriophage typing to trace the events that led to the epidemic. Policies concerning the length of time cultures should be saved and the selection of strains for bacteriophage typing can appropriately rest with the infections committee.

Special Recommendations

In addition to the recommendations which have been made for the hospital and hospital services, the conference has made certain special recommendations concerning the provision of certain services and the request for assistance from certain agencies.

TERMS AND CLASSIFICATION

An ad hoc committee on the terminology and classification of staphylococcal disease should be established. It is agreed that considerable confusion exists because of the lack of agreement in the use of such terms as apparent and inapparent infections, disease, sepsis, clinical or subclinical infection, and asymptomatic carrier. Many difficulties result from attempts to compare data in published reports that fail to distinguish the carrier state from colonization and disease or sepsis. It is strongly recommended that a subcommittee be formed to define terminology that will clearly differentiate these various terms and clarify the vocabulary applicable to staphylococcal diseases.

In addition, the committee should be requested to provide a classification and grading of infections which could be used as a guide by individual hospitals in their surveillance programs.

EDUCATION AND TRAINING AIDS

The conference recognizes the need for education and training aids to support the national program necessary for the control of staphylococcal infections in hospitals. It is strongly recommended, therefore, that the chief of the Communicable Disease Center ask appropriate interested organizations, including the American Hospital Association, the American Medical Association, and the American College of Surgeons, to designate representatives to form an interagency clearinghouse or coordinating committee for educational materials, such as audiovisual aids and literature. Such a committee, by joint sponsorship, would encourage the production of the best possible material, would avoid unnecessary duplications, and would keep all concerned aware of activities in this field.

METHODS MANUAL

Although much useful information regarding adequate sterilization and disinfection procedures has been published, it is currently scattered in many relatively inaccessible publications. It is recommended, therefore, that all available information on sterilization of special equipment, environmental disinfection, and the most recent methods of sterilization be collected in readily available manual form and distributed by the Public Health Service or some other appropriate agency.

HOSPITAL VENTILATION

Because aerial dissemination of infection may play an important role in the transmission of hospital-acquired staphylococcal disease, there is a need for a correlation of information by the medical, epidemiological, and engineering professions. Therefore, the Public Health Service is encouraged to arrange a conference of interested representatives of these professions to examine the whole problem and develop sound standards.

LABORATORY MANUAL

Attention is called to the fact that the Communicable Disease Center Laboratory in Atlanta, Ga., has recently assumed the responsibility of providing reference laboratory services for bacteriophage typing. A manual of acceptable procedures for the precise identification of staphylococci has been produced with the assistance of a subcommittee of this conference.

In Résumé

We have hammered out the many things that we know and that we do not know about staphylococci. We know the cultural characteristics of the organisms, their prevalence in hospital patients, hospital personnel, and persons outside of hospitals, and the frequency with which they are found in the hospital environment. We know how, roughly, to determine whether a strain is potentially pathogenic, how

to identify individual strains, and how to trace their spread from person to person. We do not know how to determine the invasiveness of an individual strain, nor its pathogenicity, with certainty, nor its virulence. We do not know how to prevent the spread of staphylococci from one part of a person's anatomy to another, nor from one person to another person.

We know the prevalence of strains of staphy-

agencies, especially the medical society and health departments.

It is generally recommended that surveys of discharged infants be carried on by the hospital, but it is recognized that in many communities the health department can assist with or can conduct the survey.

Surveys of this kind can obviously be conducted on either a periodic or continuous basis. Some hospitals carry on continuous surveys as part of their general disease surveillance program. Other hospitals conduct periodic surveys. Often a routine sampling of a portion of discharged patients is satisfactory. It is strongly recommended that all hospitals institute some type of survey procedure.

ANTIBIOTIC PROPHYLAXIS

In some instances, nursery epidemics appear to be self-propagating and result in a high incidence of colonization or frank disease among the infants due to an epidemic strain of high virulence. In such situations, it is possible to protect infants from colonization by administering an effective antibiotic in full therapeutic doses to all infants beginning immediately after birth and continuing until after discharge. Antibiotic prophylaxis of this type effectively prevents colonization of the infant's nose and thus his skin and allows time to search for dangerous carriers among the personnel, and to locate and correct breaks in aseptic technique. Antibiotic prophylaxis should be used only after very careful evaluation of the situation, preferably by the infections committee, and should never be used for prolonged periods nor be used on a continuous basis.

PERIODIC CULTURING

Available evidence suggests that specific strains of staphylococci which can be detected by phage typing are capable of producing nursery epidemics. In contrast with the other services in the hospitals, therefore, it may be profitable to survey the nursery personnel periodically in order to detect carriers of these particular strains. Such surveys should be undertaken routinely only in well-equipped hospi-

tals and should be considered as combined research and control procedures.

Surgery

OPERATING ROOMS

Separate operating rooms for clean and "dirty" surgical cases are not recommended. Rather, all operating rooms should be cleaned between operations and meticulously so after an operation on a contaminated case. The same meticulous care must be applied to sterilizing contaminated linens, instruments, and operative clothing.

SCHEDULING OF OPERATIONS

It is recommended that "dirty" surgical cases be placed at the end of the operating schedule.

OPERATING ROOM TECHNIQUE

The entire operating room team must be constantly alert for breaks in technique. Excessive talking (chatter) has no place in the operating room. Operating room clothing must not be worn outside the operating suite. Caps and masks must be changed between each operation. All visitors to the operating room must change completely from street clothing before entering.

SURGICAL DRESSING TECHNIQUE

Every effort should be made to minimize cross-infection through contaminated dressing carts and faulty dressing care.

PERSONNEL CARRIERS

Personnel found to be carriers of coagulase-positive staphylococci of any type should be allowed to continue on duty in the absence of an increased incidence of surgical wound infections. Even when a problem does exist, the removal of carriers should be delayed until one is certain that all other possibilities, such as defects in sterilization, have been ruled out. The one exception to this general policy is the nurse or physician who is known to be a carrier of an epidemic strain and comes from a service where there has been or is a problem.

While these recommendations apply to the inapparent carrier, it is strongly recommended that all per-

sonnel with frank staphylococcal lesions remove themselves from the surgical suite until the lesion is healed.

Medical Services

Distinct differences in the pattern of staphylococcal infections on medical services as contrasted with surgical and pediatric services are recognized. Nevertheless, it is agreed that a substantial staphylococcal infection problem exists on medical services also and the need for constant attention to aseptic techniques and control measures is just as imperative here as elsewhere. This need is important not only to prevent infections among medical patients, but also because of extensive commingling of patients among services to control spread of disease throughout the hospital.

Laboratory Services

INITIAL ISOLATIONS

Bacteriological services of a high caliber are essential to the diagnosis and therapy of staphylococcal disease and to the detection and control of hospital-acquired staphylococcal infections. It is recommended that hospitals throughout the country include in their laboratory programs the initial isolation of staphylococci, coagulase testing, and antibiotic sensitivity testing. It is recognized that there is presently a certain amount of unreliability with the disk method of antibiotic sensitivity testing, but it is noted that the Food and Drug Administration is presently adopting standards in an effort to correct these defects. While the serial tube method is admittedly more accurate, it is considered to be too time consuming and expensive for routine use. Therefore, most hospital laboratories must resort to the disk method for establishing the antibiotic sensitivity of staphylococci.

SPECIFIC DIAGNOSIS

Bacteriophage typing is not practical in most hospital laboratories at the present time, but specific diagnostic services should be available when needed. While there is little routine need for such serv-

when the staphylococcus causing an epidemic in a nursery is sensitive to a specified antibiotic. The surgeons even differed as to whether the poorly absorbable antibiotics should be administered prior to bowel surgery, although they did agree that antibiotics will not prevent infections from developing in clean surgical wounds. The suggestion was made that spraying of the noses of carriers may eliminate the carrier state in some persons, but it was recognized that more study is needed in this area.

Of course, a most important means of control is to eliminate the infection at its source, in other words, to treat the patient who has a staphylococcal infection. This requires the highest degree of skill and knowledge on the part of the clinician to diagnose the disease properly, to interpret the tests run by the supporting laboratory, to choose the proper antibiotic from among the number at hand today, and to administer it properly. When the clinician is not sufficiently familiar with this area, he should not hesitate to call for advice.

A Reporting System

Infections cannot be controlled unless we know that they are there. This requires reporting of staphylococcal infections by certain responsible parties within each hospital. The initial report has been made in different hospitals by house officers, nurses, or personnel in the hospital laboratory. Different methods may be feasible for different hospitals. Whichever one is used, the reports should go to an infections committee, which should be set up in each hospital. Such a committee should be

broad in its interest, representative in its personnel, and of sufficient authority to make sure that its suggestions will be carried out.

Reporting should be amplified by checkups of susceptible groups, such as newborns, after they have left the hospital. Several feasible methods were suggested for these surveys. Most important is that they have the full cooperation of the hospitals, of the medical profession, and of the health officer.

Reporting and control are not successful without proper definitions. Agreement could not be reached on any one system of classification of staphylococcal infections. Accordingly, it was suggested that the Public Health Service set up a committee to recommend a proper classification.

None of the measures for control will have any effect without continuous, interesting, and authoritative publicity. Educational programs are needed within the hospital for all the personnel from the lowest to the highest. These can be aided by health authorities and local and national medical associations by the provision of information, teaching aids, and speakers, and the initiation of communitywide meetings from time to time.

Finally, and most urgently, we need more research on staphylococci and the infections they cause. I have already mentioned some of the things we need to know. Funds are needed for intramural and extramural research on the practical problems of staphylococcal infections, their communicability and control, and especially on fundamental problems of host resistance to the staphylococcus and how it may be strengthened.

—HARRY F. DOWLING, M. D., *professor of medicine, College of Medicine, University of Illinois, Chicago.*

lococci which are resistant to various antibiotics in different populations, and we know some of the factors that cause resistant strains to appear; we don't know how to prevent the appearance of such strains in hospitals (short of exposing no one at all to that particular antibiotic), and we don't know how to replace a resistant strain with a sensitive one.

We know that staphylococci are spread among patients and personnel of hospitals, that they may cause endemic infections in any hospitalized patients and epidemics chiefly among newborns and surgical patients. We don't know the most frequent pathways of spread, whether carriers or environmental sources are the most important, nor what makes epidemics start. We know that certain strains are more frequently encountered as epidemic strains; we don't know what causes them to become epidemic strains. We can often trace an epidemic to an infected person or carrier; we cannot tell why some other infected person or carrier did not start an epidemic. We know that the removal of a carrier or strict attention to aseptic techniques sometimes appears to stop an epidemic; we fear that these measures will not always do so.

We know some conditions that increase patients' susceptibility to staphylococcal infections, but do not know why some persons develop staphylococcal infections while others fail to do so under apparently identical circumstances. Finally, especially as a result of this conference, we don't know any cause for wild alarm and gnashing of teeth over the staphylococcal problem; we do know that there is an important and compelling job to be done which calls for rolling up our sleeves and getting to work.

Techniques of Control

How should we go about controlling staphylococcal infections? Since we cannot easily get rid of the staphylococci that are causing or may cause disease within a hospital, most recommendations in the discussions were directed at limiting their spread. The first barrier is at the entrance of the hospital or the ward. Perhaps some patients with staphylococcal infections could be better nursed at home. Hos-

pital personnel, from the chief of staff down, should not contact patients if the staff member has a staphylococcal skin lesion or is known to have produced infections in patients. During an epidemic in a critical area such as a nursery or an operating room, personnel may be removed if they are carrying the epidemic strain.

The second barrier is within the hospital, between personnel and patient or between patient and patient. The conferees unanimously recommended complete isolation of patients with staphylococcal infections, wherever practicable. They urged that careful techniques be observed in the performance of operations, along with the proper sterilization of instruments and apparatus, the proper technique in dressing wounds, careful disposal of discharges and sputum, the washing of hands after examining patients with infected lesions, and the removal of staphylococci from that susceptible animal, the newborn infant, by washing his skin with special preparations.

With regard to spread through the air or from objects in the environment, everyone recognized the need for more knowledge. We do not know enough about the importance of proper ventilation (except in the operating room and rooms for dressing wounds), of washing floors and walls, of sterilizing blankets, of spacing beds and cribs; we do not know the value of rooming-in procedures for infants and so on. It was emphasized again and again that there is no simple and easy panacea for the control of intrahospital staphylococcal infections. Many things must be done, some of which may be unnecessary; the wisest course is first to close the most likely pathways of spread of infection and proceed to the others if necessary. In the last extremity, nurseries or wards may be closed, and, almost everyone agreed, the operating room might have to be closed, too.

Antibiotics, which have no doubt been responsible for some of our trouble with the staphylococci, are of little help in getting us out of trouble. Their role in the prevention of infections is limited to certain specific situations. There is no evidence that they will prevent staphylococcal infections from developing in hospitalized patients except perhaps

26 infants infected with the epidemic phage type 80/81 during a nursery outbreak (4). During 5 months of observation about three-fourths of the mothers and one-third of the fathers and siblings were shown to be carrying phage type 80/81 in their nasopharynx on one or more occasions. Eleven of the 26 families were still infected at the end of the study. A variety of skin infections and subcutaneous abscesses occurred in about 40 percent of the infected mothers and fathers and 70 percent of infected siblings. Shaffer and associates have reported similar findings (5). At the end of the 18 months of his study, 9 of 20 families were still infected.

These investigations have provided convincing evidence that epidemic strains of staphylococci carried by infants at discharge are rather readily transmitted to family members, persist for long periods within the family, and are responsible for endemic staphylococcal disease within the family unit.

Further evidence that the nursery epidemics may result in an increased incidence of community disease has been provided by a comparison of families of infants born during epidemic and nonepidemic periods in the same hospital. In one recent study, investigations were made of 1,076 families of infants born during a nursery epidemic of 3 months' duration and 211 families of infants born during a nonepidemic period (6). In 25 percent of the families of epidemic infants one or more members of the family group had developed staphylococcal disease 1 to 5 months following the birth of the baby, while 3 percent of families of nonepidemic infants gave a similar history. Eleven percent of 3,975 family contacts developed disease during the epidemic period, while 0.8 percent of 506 family members developed a similar illness during the nonepidemic period. If an infection rate of about 1 percent is accepted as a rough approximation of the level of endemic community disease during this period, then the difference between this and a rate of 11 percent is an approximation of the magnitude of increase in community infection which resulted from the nursery epidemic.

If the magnitudes expressed here are reasonably accurate and representative, it follows that

a significant increase in the level of community staphylococcal disease will follow uncontrolled type-specific nursery outbreaks. We are unaware of systematic studies of the transmission of epidemic strains from these hospital-associated families into the general community, but fragmentary evidence suggests this to be the case. Certainly the persistence of the strains within the family unit for such long periods make it likely that transmission to friends and relatives will eventually occur. In this event the "crude equilibrium between the public at large and the ubiquitous staphylococci" referred to by McDermott as appearing relatively stable in 1956 (7) might well be shifted in favor of the staphylococcus and result in an absolute increase in the level of endemic community disease.

It is difficult for one who has not observed family staphylococcal disease to be impressed with the seriousness of the situation. We observed one family whose infant was born in October 1954 in a nursery during an epidemic caused by phage type 80/81. The infant developed a few blebs prior to discharge and severe staphylococcal impetigo after he went home. Since then this family has virtually never been without staphylococcal disease in 1 or more of its 5 members. The father and 1 of the 3 children have been hospitalized for incision and drainage of abscesses. The two other children and the mother have had incision and drainage as outpatients. On three different occasions the entire family has been treated with antibiotics in an attempt to eradicate the family infection. It is conservatively estimated that the cost in antibiotics and medical care, exclusive of hospitalization, has been well in excess of \$1,500. Type 80/81 has been repeatedly isolated from the nasopharynx and lesions of these individuals and was last isolated in July 1958, nearly 4 years after the epidemic.

The history of another family has been related to us by their private physician. He has been attempting to eradicate type 80/81 from this family for well over a year. In this case there had been no recent direct hospital contact. Two siblings had vacationed for a month with an uncle who had been having recurrent boils and carbuncles for a year, his problem

Hospital-Acquired Staphylococcal Disease and the Community

FREDERICK H. WENTWORTH, M.D., M.P.H., ADAH L. MILLER, R.N.,
and BERTTINA B. WENTWORTH, B.S.

HOSPITALS provide vitally needed services to practitioners of medicine and to the community at large. Anything which tends to disrupt hospital services or interfere in any way with their optimal function is of real concern to the community. Hospital-acquired staphylococcal disease can certainly decrease the efficiency of hospital operation by prolonging the patient's hospital stay, increasing the cost of medical care, and, in some cases, jeopardizing the patient's recovery. The community and community agencies may be expected for these reasons to be vitally interested in the control of the problem.

Recent studies of the epidemiology of hospital-acquired staphylococcal infections have established additional reasons for concern. It is now very clear that the hospital with an uncontrolled staphylococcal disease problem may act as a focus of infection for the community itself. It is also clear that many patients infected while in the hospital do not develop overt disease until some time following their discharge and thus the detection of the disease in the community becomes essential to the delineation of the hospital problem and its control. Evidence supporting these concepts is at the

moment most convincing in the case of strain-specific staphylococcal infections acquired in hospital nurseries.

Two outstanding features of the epidemiology of nursery outbreaks have been the number of infants who develop the first signs of disease following discharge from the hospital and the frequency of postpartum breast abscess among mothers. Studies on the nasal flora of women on admission to the maternity service and at the time of discharge, as well as that of their infants, indicate the infants (1) are the source of the staphylococcus responsible for the breast abscesses. These studies also demonstrated that in the vast majority of cases transmission from infant to mother takes place in the home. These findings suggested the possibility of simultaneous or subsequent transmission to other members of the family and the establishment of endemic staphylococcal disease within the family group.

Colbeck, while studying nursery outbreaks in Winnipeg in 1949, found this to be the case (2). In the families of 10 infants born in an epidemic period, he demonstrated recurrent suppurative disease among family members during several months following the discharge of the infant and mother from the hospital. Staphylococci isolated from the lesions in family members appeared to be of the same phage type as that responsible for the nursery outbreak. In 1953 Kempe, reporting the family as a reservoir of childhood infections, includes an excellent description of family staphylococcal disease persisting over a 9-week period (3). More recently we have studied the families of

Dr. Wentworth is medical coordinator of disease control activities in the Ohio Department of Health, where Mrs. Miller is a communicable disease nursing consultant and Mrs. Wentworth is head of the research laboratory. The paper was presented at the National Conference on Hospital-Acquired Staphylococcal Disease in Atlanta, Ga., September 16, 1958.

Nursing Opportunities in the Public Health Service

Staff nurses, head nurses, and supervisors are employed in 16 major Public Health Service hospitals in the United States and in 55 Public Health Service Indian and Alaska native hospitals. Clinical nurses are also employed in the Clinical Center, the Service's 500-bed research hospital at the National Institutes of Health. Twelve of the 16 hospitals provide general medical and surgical services; 1 is exclusively for tuberculosis cases; 2 are for treatment of narcotic addiction and other neuropsychiatric disorders; and 1 is the only hospital in continental United States devoted exclusively to care of leprosy patients. There are opportunities for teaching and training at all levels.

Total bed capacity of the 16 major hospitals in the United States ranges from 135 to 1,250 beds; the total capacity in the Indian and Alaska native hospitals is about 3,800, with bed capacity per hospital ranging up to 400.

In the field of public health nursing, opportunities are available in epidemiological investigations and studies, in public health activities in the Indian health program, in general and special public health programs (such as heart disease control, tuberculosis control, venereal disease control, and quarantine activities), and in technical assistance programs overseas.

Entrance salaries for Public Health Service professional nurses were recently raised by 10 percent. They now range from \$4,040 a year for GS-5 beginners (formerly \$3,670) to \$9,890 for GS-13 program heads (formerly \$8,990). For nurses with a year of experience, the new rate is \$4,490 a year (formerly \$4,080).

Further information on nursing opportunities may be obtained by writing to the Surgeon General, U. S. Public Health Service (P), Washington 25, D. C.

having started shortly after he was discharged from the hospital following elective surgery. The 80/81 strain was isolated from his lesions, and the hospital in which he had surgery was found to have a staphylococcal disease problem.

Although not representative, these cases illustrate the extent to which infection may become a serious problem for the family and point up the very great difficulties of eradicating the infection from the family group. Treating the family as a unit with an appropriate antibiotic appears to be effective in some instances, but by and large results in failure. According to a personal communication in 1958, Colbeck has had some encouraging results following thorough disinfection of the household. It is probably fair to state, however, that at the moment there is no really satisfactory approach to the eradication of the epidemic strains from the family and that, in a good percentage of the cases, staphylococcal disease may be expected to recur over long periods despite repeated attempts at eradication.

These findings certainly underline the importance of controlling nursery outbreaks. In addition, they have certain practical implications. During nursery epidemics it is not unusual for the majority of infants to develop their disease following discharge from the hospital. The number of cases of frank disease occurring in the nursery are frequently below the threshold of recognition. Unless the infants developing postdischarge disease are properly diagnosed and reported back to the hospital, an epidemic situation may continue undetected for long periods. This implies that the prompt detection and control of hospital epidemics requires the cooperation of individuals and agencies outside the hospital. The adequate provision of laboratory services, a reporting system, and survey techniques for the detection of lesions unattended or unreported by physicians are essential to the control of the hospital situation. With respect to nursery outbreaks, then, the universe of concern clearly extends beyond the hospital walls and includes the entire community of which the hospital is a part.

Whether these findings apply to the post-surgical infections of the hospital-infected adult medical patient is less clear. It has been

shown repeatedly that hospital patients acquire antibiotic resistant strains of staphylococci during their hospital stay and are carrying them on their skin or mucous membranes at the time of discharge (8, 9). Some degree of transmission to family members of nonepidemic "hospital strains" resistant to antibiotics has been demonstrated (8), but the seriousness of a potential increase in the endemic level of community staphylococcal disease needs further exploration. Infections with antibiotic resistant strains certainly present more difficult therapeutic problems and appear to be resulting in a higher case fatality rate than infections with sensitive strains (10, 11). As the hospital is a primary community source of antibiotic resistant staphylococci, hospital-acquired staphylococcal infections are a threat to the community. While the role of official public health agencies and an organized community in the detection and control of these infections is less clear than in the case of nursery disease, the need for community interest and awareness and the responsibility of community agencies for the provision of service to assist the hospital is surely as great.

In summary, it would appear fair to state that hospital-acquired staphylococcal disease is a hazard to the community because it threatens the efficiency of hospital operation and because, at least in the case of type-specific nursery disease, acts as a focus for a serious increase in the level of community-acquired staphylococcal disease. In addition, it is likely that hospital epidemics may go undetected unless the hospital-acquired disease occurring after discharge is promptly found and brought to the attention of the hospital. Organized community effort to provide epidemiological and laboratory services, the prompt reporting and analysis of incidence data, and surveys for hospital-associated morbidity undetected by other means are essential to the control of hospital epidemics.

lation of all cattle reacting to tests and regulates the importation of any cattle into the area according to whether the animals, or herds from which they originate, are infected or not. By 1956 all the counties in the State were operating under this plan.

The area plan of control, as it is operated in Minnesota, has been successful. There has been a steady increase in the number of counties that have attained a certified status, except during World War II and the immediate post-war period when progress in eradication nearly came to a standstill.

More important, perhaps, is that the testing for recertification at the intervals required by State law and the Uniform Methods and Rules

of the U. S. Department of Agriculture continues to show a decrease in the incidence of brucellosis in cattle. This favorable progress is probably attributable to the Minnesota law and regulations that provide for the blood agglutination test of all cattle as the basis of the eradication program. The milk ring test and calfhood vaccination, while used extensively, are considered only as supplements to the systematic blood testing of all cattle.

Effects of Program

Figures 1-4 compare the number of cattle (taken from the U. S. Department of Agriculture's official estimates of all cattle and calves on farms on January 1 of each year) with the number of human cases of brucellosis, the percentage of counties under the area certification program, and the number of cattle reactors to brucellosis which were slaughtered. From these figures it can be seen that from 1927 to 1948 when numbers of cattle increased or decreased, there was usually a corresponding increase or decrease in the number of human cases of brucellosis. From 1949 to 1956, however, this relationship was no longer evident.

It is apparent from the data in the figures that the area control program was effective in reducing human cases of brucellosis. During 1949-50 the number of counties joining the area test program began to increase sharply. The years 1949-51 were the beginning of a rise to new heights of the cattle population and the number of cattle reactors slaughtered. Concurrent with these upward trends there was a marked downward trend in the number of reported human cases of brucellosis.

Table 2 shows the number of counties certified year by year in Minnesota and the case rates in the certified counties as contrasted with those in the noncertified counties. The life table approach has been used in preparing this table.

The total experience shows that since 1940, when the first counties were certified, the case rate has been 3.12 times greater in noncertified than in certified counties.

Each year since 1942, except 1955 and 1956, the case rates have been significantly higher in noncertified counties. In 1955 and 1956, how-

Coincident with progress in the eradication of brucellosis in Minnesota's cattle, the number of human cases have significantly decreased.

Effect of Eradicating Brucellosis in Cattle on Incidence of Human Cases

JOE R. HELD, D.V.M., HENRY BAUER, Ph.D., and RALPH L. WEST, D.V.M.

BRUCELLOSIS was first reported in humans in Minnesota in 1927, and there was a general trend toward an increasing number of cases until 1946. Since 1946, however, the trend has been downward. Whereas the case rate per 100,000 population was 0.24 in 1927, it was 1.94 in 1956. The maximum case rate of 13.84 occurred in 1946 (table 1). The purpose of this study is to show the effect of the area certification program on this rise and fall in the reported number of human cases of brucellosis.

One can assume that, as with any disease, an awareness of the disease's presence in the State was needed before the majority of cases could be diagnosed properly as brucellosis. In 1927, serologic and bacteriological services were introduced into the laboratories of the Minnesota Department of Health to aid in the diagnosis of brucellosis. These services were accepted

by practicing physicians and have been used increasingly since that time.

It should be noted here that the only cases counted by the Minnesota Department of Health are those confirmed by an agglutination test with a titer of at least 1:80, accompanied by clinical symptoms suggestive of brucellosis, or confirmed by isolation of the organism from blood cultures.

Other factors undoubtedly affecting the number of human cases of brucellosis in Minnesota are the number of cattle in the State and the extent of the area certification program pertaining to brucellosis in cattle.

Statewide pasteurization of milk may also have played a role in decreasing the incidence of infection in humans. A law requiring pasteurization was enacted in 1949, and a regulation prescribing minimum standards for grade A milk became effective under that law on March 31, 1952. No attempt will be made in this paper to evaluate the effect of pasteurization in itself, since for our purposes the presence of *Brucella* organisms in milk merely signifies an infected animal.

In 1939 the Minnesota Legislature enacted a law authorizing the State Livestock Sanitary Board to control and eradicate brucellosis in cattle by means of an area plan. Under this plan, all cattle owners in a specified area are required to participate in a testing program. The law also provides for the slaughter or iso-

Dr. Held, assistant veterinarian, Communicable Disease Center Activities, Public Health Service, at the time of this study, is taking graduate work in public health at Tulane University. Dr. Bauer is director, division of medical laboratories, Minnesota Department of Health. Dr. West is secretary and executive officer, Minnesota State Livestock Sanitary Board. Dr. Herman Kleinman, chief, section of chronic diseases, Minnesota Department of Health, assisted in the statistical analysis of the data.

ever, there was a great shift in the population from a noncertified to a certified status. This fact, coupled with the incubation period of brucellosis and the difficulties that sometimes arise in establishing a diagnosis, probably contributes to creating a lag effect, so that cases that actually occurred under noncertified conditions are being reported after the area has become certified. The difference in case rates in 1956 is not statistically significant, which tends to uphold this hypothesis.

Brucellosis in Humans From Cattle

The question may arise as to whether or not the real problem of brucellosis in humans in Minnesota originates from contact with cat-

Figure 1. Number of cattle on farms, Minnesota, 1927-56.

Figure 2. Reported number of human cases of brucellosis, Minnesota, 1927-56.

tle. In addition to blood samples submitted routinely for *Brucella* culture, the division of medical laboratories of the Minnesota Department of Health attempts to obtain blood specimens for all individuals who show a *Brucella* antibody titer of 1:320 or higher. Of course, by the time arrangements are made to have blood submitted for culture, the patient is not always in that stage of the disease where there is bacteremia.

*With the northward movement of yellow fever, the Public Health Service is intensifying its program for control of *Aedes aegypti*, particularly in international traffic zones of the yellow fever receptive area of the United States.*

Measures Against Yellow Fever Entry Into the United States

JOHN H. HUGHES, Ph.D., and JOHN E. PORTER, Ph.D.

THE SURGEON GENERAL of the Public Health Service is authorized by the Public Health Service Act to make and enforce regulations for preventing the introduction of diseases of man into the United States and their spread in this country. The Division of Foreign Quarantine has the responsibility for preventing the importation of disease. This responsibility requires enforcement of quarantine regulations applicable to all traffic arriving by air, sea, or land.

Although there are other important diseases affecting man, the Public Health Service foreign quarantine regulations place particular emphasis on smallpox, cholera, plague, louse-borne relapsing fever, louseborne typhus, and yellow fever. These diseases are recognized by the World Health Organization and by the health departments of many countries as the six quarantinable diseases. Five of them involve insects in their transmission and therefore are of particular interest to entomologists.

There are a number of entomological problems in quarantine operations, but at this time particular consideration will be given to the detection and control of *Aedes aegypti* Linn. at airports, in dock areas of seaports, and at land-entry points. *A. aegypti* has played an important role in the transmission of yellow fever in many countries around the world, and it is the only widely distributed mosquito in the

United States that is known to be a natural transmitter of the yellow fever virus.

However, *Haemagogus equinus*, a species of mosquito found naturally infected with yellow fever in Guatemala (1), occurs near Brownsville, Tex., in limited numbers. This forest-type mosquito was collected in the Brownsville area in 1955 by Trapido and Galindo (2), who found it in tree holes of thorn scrub; in 1957, by Eads and Strom (3), who found it in water in tree holes of Texas ebony, *Pithecolobium flexicaule*; and by Strom (unpublished record). Breland reported *H. equinus* from cavities in the Texas ebony and from a hackberry tree (4). This interesting addition to the mosquito fauna of the United States has a range extending southward from the Brownsville area to Colombia, South America, and is the only representative of the genus *Haemagogus* reported in the United States.

Historical Note

Historically, yellow fever in its urban form has occurred on numerous occasions in epidemic

Dr. Hughes is chief, Entomology Branch, Division of Foreign Quarantine, Public Health Service, Washington, D. C., and Dr. Porter is the principal entomologist at the Public Health Service Quarantine Station, Miami, Fla.

The isolations that are made, however, represent a random sampling of all reported cases. Table 3 gives the number and type of *Brucella* organisms isolated from blood cultures for the period 1932 to 1956. From this information it can be seen that the majority of patients were infected with *Brucella abortus*. Since it is known that in animals *B. abortus* is mainly found in cattle, it seems safe to assume that the majority of human cases in Minnesota resulted from contact with cattle.

Summary

Coincident with progress in the eradication of brucellosis in cattle, there has been a signifi-

cant reduction in the number of human cases.

From 1927 to 1948, when the number of cattle increased or decreased, there was a corresponding increase or decrease in the number of human cases of brucellosis in Minnesota. But from 1950 to 1956 the number of human cases declined markedly in spite of a high increase in the cattle population. This change in trend results from the elimination of some sources of human infection by the acceleration of the program for eradicating the disease in cattle.

Since 1940, when the first counties were certified as brucellosis free, the total experience has shown that the human case rate for brucellosis has been 3.12 times greater in noncertified areas than in certified areas.

Infant Care

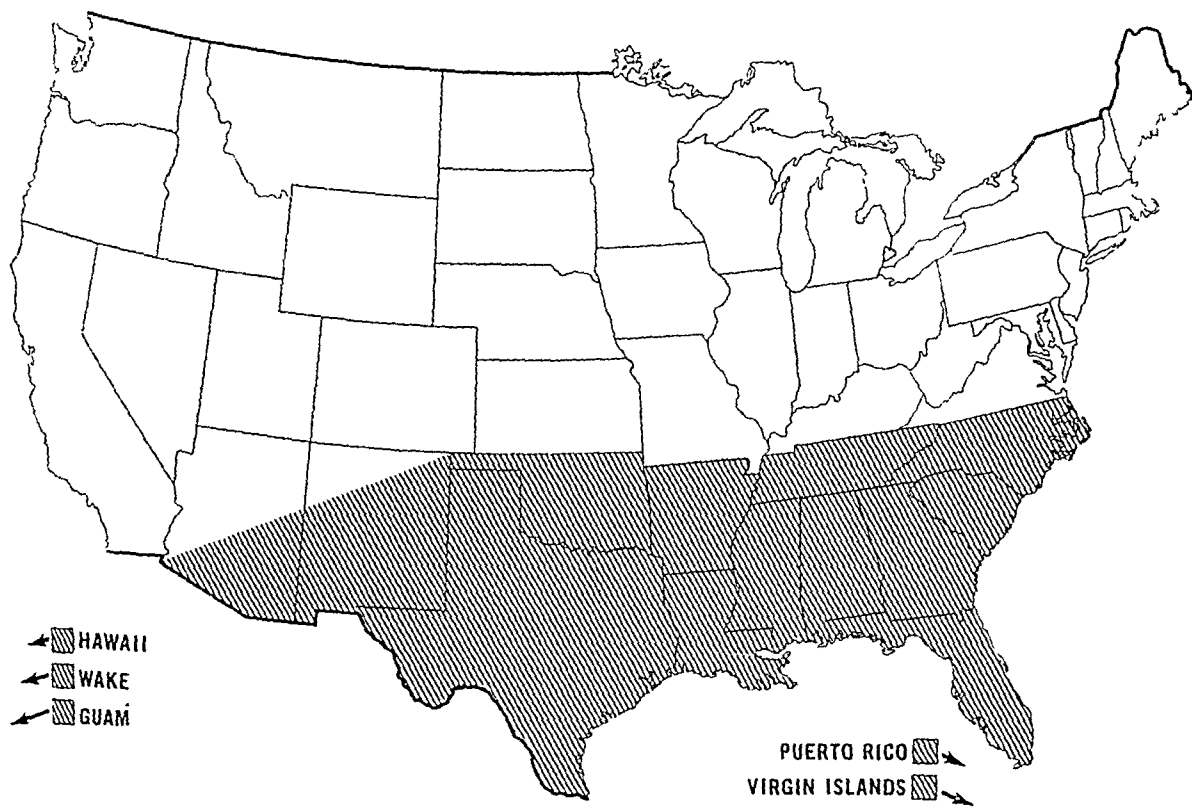

The booklet *Infant Care* first published in 1914, soon after the establishment of the Children's Bureau, is now in its 10th edition. In addition to 40 million copies sold in this country, it has been translated and widely distributed abroad.

The 10 editions reflect the history of child care practices in the United States. In 1914, for example, fathers were advised not to play with an infant son or daughter because it might result in "nervous disturbances of the baby and upset his regular habits." Experts now agree that infants need the attention of their fathers as well as their mothers.

In 1914 *Infant Care* did not advise even strained fruits until a baby was 7 or 8 months old, and solid foods were not recommended until after a baby was 1 year old. Today's *Infant Care* baby gets fruit juice at 2 weeks and solid foods within the first few months of his life.

The Children's Bureau is planning the 11th revision of *Infant Care*. As in the past, the Bureau will have the advice of a technical advisory committee, composed of physicians who represent four major medical societies, and the guidance of parents, psychologists, nurses, nutritionists, anthropologists, social workers, parent educators, and others.

Yellow fever receptive area in the United States.

yellow fever receptive area (see map) the incidence of *A. aegypti* is considered sufficiently high to support yellow fever transmission, particularly during the warm months of the year. The delineated area will be modified as may be necessary to reflect changes in the distribution pattern of the mosquito.

Preventing Entry Into the U. S.

The United States has a human population which presumably is not immune to yellow fever; it has a widespread distribution of a mosquito vector of the disease; and it has a history of outbreaks of the disease. Also, the disease is present in areas comparatively close to our possessions in the Caribbean area and to our southern ports and land-entry points. Furthermore, modern rapid transportation makes it possible for persons in the incubation stage of the disease and infected mosquitoes, monkeys, or other animals to bring in the yellow fever virus from countries where it now occurs.

Although the last outbreak of yellow fever in this country occurred more than half a century ago, and no cases of the disease have been reported on ships or other conveyances arriving at United States ports for more than 30 years, we cannot be assured of its continued absence from this country.

Activities directed toward preventing the introduction of yellow fever into the United States are being carried on at various ports of entry as a part of a broad quarantine program. These include:

- Requirement of a valid yellow fever vaccination certificate of any traveler from a yellow fever area who arrives in or is destined for the yellow fever receptive area within the incubation period of the disease.

- Medical examination of persons arriving from yellow fever areas and, if necessary, their surveillance or isolation.

- Inspection of monkeys and certain other primates coming from yellow fever areas, and requirement of immunization against the disease or retention in a mosquito-proof crate or

proportions in the United States. The last epidemic in this country occurred during the period July to December 1905, with 8,399 cases and 908 deaths (5).

Twenty-six cases of yellow fever, exclusive of laboratory cases such as those reported by Berry and Kitchen for the period 1929-31 (6), have been reported in the United States since the 1905 epidemic. Twenty-three of these were intercepted on ships in international traffic which arrived at Public Health Service quarantine stations. These cases are reported in the annual reports of the Public Health Service as follows:

Fiscal year	Cases	Deaths
1907.....	6	1
1908.....	3	3
1911.....	1	0
1912.....	1	0
1913.....	1	0
1917.....	2	0
1922.....	5	0
1923.....	3	0
1924.....	1	0

¹ Suspected.

In addition, one case of unknown origin occurred in New Iberia, La., in August 1906; another occurred in Honolulu during October 1911 in a quarantine station employee who was detailed as a guard on a vessel on which a case of yellow fever was present; and an immigrant from Mexico was reported to have died of yellow fever in Houston, Tex., October 8, 1924 (7).

Northward Movement

One of the current problems facing the Public Health Service and other health agencies and involving entomology and related disciplines is the northward movement of yellow fever in the Americas. This disease was reported in both its urban and sylvan forms in Trinidad, B. W. I., in 1954 (8, 9) and in its sylvan form in various countries of Central America following its appearance in the Pacora area of eastern Panama in 1948. Human cases of sylvan yellow fever occurred in Panama during the period 1948 to 1952, in Costa Rica in 1951 and 1952, in Nicaragua in 1952, 1953, and 1954, and in Honduras in 1954 (10). According to the Weekly Epidemiological Reports of the Pan American Sanitary Bureau, in Panama the disease was again detected in man in 1956 and 1957, and

human cases were reported in Guatemala in 1957. Also, as reported in the Weekly Epidemiological Reports, sylvan yellow fever occurred in the simian population in the forested areas of the countries enumerated, and in 1957 the disease in monkeys was found in British Honduras.

The yellow fever virus was isolated from naturally infected *Aedes mesodentatus* K. and K., *Aedes equinus* Theob., and *Sabethes chloropterus* Humboldt collected in Guatemala in 1956 (1), and from *Aedes lucifer* (H. D. and K.) collected in Panama in 1957 (11), thus adding substantially to the list of known and potential transmitters of the yellow fever virus in nature. Sylvan yellow fever, as reported in the Weekly Epidemiological Reports, has occurred in all countries of Central America except El Salvador. Thus, only Mexico separates the continental United States from the Central American countries where yellow fever is known to occur.

Receptive Areas

Under the terms of the World Health Organization International Sanitary Regulations now in force (12), areas in which the virus of yellow fever does not occur, but in which *A. aegypti* or any other domiciliary or peridomestic vector of yellow fever is to be found under conditions that would permit development of the virus in the event of its introduction, are considered receptive to this disease and must be so declared. Thus, the area of the United States, including insular Territories and possessions, where *A. aegypti* occurs constitutes our yellow fever receptive area. Although yellow fever does not occur in this area, it might conceivably be introduced and become established, at least temporarily.

The yellow fever receptive area of the United States, as delineated by the Public Health Service and reported to the World Health Organization in 1953, in accord with article 70 of the International Sanitary Regulations, comprises 13 southern States, Puerto Rico and the Virgin Islands in the Caribbean area, and Hawaii and Wake Island in the Pacific area. Also, Guam has been added to this list, as reported in the Weekly Epidemiological Record of the World Health Organization, January 1958. In the

of Florida and Texas. During the period July 1957-June 1958, the Miami entomological unit made *A. aegypti* surveys in airports and dock areas in more than 25 localities in Florida, including Fort Pierce, Jacksonville, Miami, Pensacola, St. Petersburg, Tampa, and West Palm Beach. *A. aegypti* breeding was observed in 6 of the Florida airports inspected, with indexes as high as 4.0 percent. Breeding was also detected in 10 of the Florida docks inspected, with indexes as high as 9.0 percent. Outside Florida, similar surveys made during the spring of 1958 in a number of airports and dock areas along the Atlantic coast as far north as North Carolina revealed sparse breeding in one dock area in late June.

Most of the *A. aegypti* breeding was localized in overhaul and salvage areas of the airports inspected and was not observed in the active traffic areas. Comparable conditions existed in the dock areas. Control measures included application of DDT spray and, when feasible, removal or destruction of containers or making them unsuitable for supporting *A. aegypti* breeding. Port authorities and health officials in the area surveyed were apprised of the control problem and of results obtained in the surveys.

One finding of particular interest made by the Miami entomological unit was extensive *A. aegypti* breeding at the Key West, Fla., main city dock in water contained in old tires. This observation, made November 13, 1957, is particularly significant in view of the fact that this mosquito had not been reported on Key West since November 1948 (J. A. Mulrennan in personal communication, 1958). Although it is not known when or actually how *A. aegypti* returned to that island, continuous entomological surveillance is obviously necessary if costly and potentially dangerous health problems of this type are to be prevented.

During the early months of the program it has been possible to give only limited attention to the airport and dock areas in New Orleans with reference to *A. aegypti* breeding. However, no evidence of this mosquito has been found in the surveys. The program in this locality is being accelerated.

Negative results also were obtained in searches for *A. aegypti* at airports and in dock

areas of several port cities in Texas, including Brownsville, Houston, Galveston, and Corpus Christi, during the year ending June 30, 1958. Numerous potential *A. aegypti* breeding places were inspected and treated.

Outside the continental United States, emphasis is being placed on extension of the control program to international traffic areas in Hawaii, where the mosquito is present, although apparently in diminishing numbers, and in Puerto Rico and the Virgin Islands.

The current intensification of *A. aegypti* control activities by the Public Health Service should provide exact knowledge on which to base plans, not only for eradication of *A. aegypti* from the United States, but for a continuing quarantine program to prevent reintroduction of either the virus or the vector.

other structure for a minimum of 9 days immediately before arrival in the yellow fever receptive area.

• Disinsectization of aircraft and ships and the entomological surveillance of airports and dock areas (13).

***Aedes aegypti* Control Programs**

For many years the control of *A. aegypti* and other mosquitoes has been an important part of the disease control program of the Public Health Service. During the latter years of yellow fever occurrence in this country, various sanitary measures, including mosquito control, often were employed on ships arriving at United States ports (14). With the advent of international aerial traffic, disinsectization measures were incorporated into the quarantine clearance requirements, particularly for aircraft arriving from foreign countries where yellow fever was prevalent. Supplemental to the disinsectization measures applied to aircraft and to some ships, an entomological surveillance and control program was put into operation and maintained at airports (15) and in dock areas having a southerly location and where international traffic is most active.

Prior to and during World War II the Public Health Service made other efforts to reduce the population of this mosquito in some of the major airport and seaport areas in the south. In the late 1930's the Division of Foreign Quarantine cooperated with certain counties in southern Florida in conducting mosquito abatement programs to reduce the *A. aegypti* population, particularly in areas of heavy international traffic. With the outbreak of hostilities the Service expanded these activities and, in collaboration with State health agencies, conducted a more extensive campaign in ports of entry in the south. These programs were directed toward reduction in the number of *A. aegypti*, as a means of protection against the introduction and establishment of yellow fever (16), and toward the training of available personnel, who could be called upon to assist in any part of the country, should yellow fever (or dengue) be introduced. Although the Public Health Service *A. aegypti* control program was discontinued after the close of World War

II, other, more limited programs have been conducted by local health departments.

In July 1957 the Public Health Service appropriation provided limited funds for the Division of Foreign Quarantine and the Communicable Disease Center to collaborate in investigations of *A. aegypti* control in the United States, including an evaluation of the threat of yellow fever in this country. These investigations should enable the United States to comply more fully with the terms of article 20 of the World Health Organization International Sanitary Regulations (12), which state, "Every port and the area within the perimeter of every airport shall be kept free from *Aedes aegypti* in its larval and adult stages."

The Division of Foreign Quarantine's portion of this broader and more comprehensive program consists of the establishment of entomological units at Miami, Fla., Brownsville, Tex., and New Orleans, La. These units will survey their respective base stations, and other areas as directed, to determine the presence and abundance of the yellow fever mosquito on various types of conveyances and at airports, dock areas of seaports, and border-crossing points in the yellow fever receptive area. Control measures and cleanup campaigns will be carried on in conjunction with the surveys. It is expected that some investigations and observations will be made with respect to possible insecticide resistance, survey and control techniques, biology and behavior of *A. aegypti*, and other aspects of prevention of importation of yellow fever.

The Communicable Disease Center will make surveys and otherwise obtain information to determine the distribution and abundance of the urban vector of yellow fever throughout the yellow fever receptive area and will carry on a project in a coastal city to ascertain costs and methods involved in eradication of *A. aegypti* in a specific urban area and the applicability of similar programs in other urban communities in the receptive area. As resources permit, CDC will make other field and laboratory investigations apropos of an *A. aegypti* and yellow fever control program.

The most active phase of the *A. aegypti* control program carried out by Division of Foreign Quarantine workers has been confined largely to the more important international traffic areas

Free Medical Care in Cities

SELMA MUSHKIN, Ph.D., and BEATRICE CROWTHER, B.A.

Approximately 7 percent of urban residents reported receipt of free medical services in 1950. Almost 4 of each 10 persons reporting receipt of some free services indicated they received physician services free; 1 of 5 reported hospital services; and another 1 of 5 reported laboratory tests, immunizations, or X-rays. More than 4 of each 10 persons reporting free care indicated they received free care in public hospitals or through public assistance or private voluntary agencies.

A larger proportion of persons spending \$500 or more out-of-pocket for medical services reported free care than of those spending smaller amounts for medical services. Almost 9 percent of persons 19-44 years of age reported free care as compared with 4 percent of the population under 6 years of age. About 1 of 8 urban household members hospitalized during 1950 reported some free hospital services.

ONE important financial aspect of medical services is the volume of free care provided for families by a multiplicity of public and private agencies. There is a paucity of data on the volume and relative importance of public and private aid in meeting medical care needs. In 1950, public expenditures for health and medical services aggregated about \$2.4 billion; and voluntary health and welfare agencies spent \$370 million (1).

Household surveys can provide only a partial picture of free care, for the types of medical services that are financed by private and public aid often include long-term institutional care, such as that given in mental hospitals, which removes the recipient from the household. Yet it is of interest to determine even in an incom-

plete way the numbers of persons receiving free care, the nature of this care, and the types of agencies providing it.

In view of the interest in this aspect of financing medical services, we processed data on free medical care reported in a subsample of family interviews. The information was gathered by the Bureau of Labor Statistics from 12,500 urban families in its survey of consumer expenditures in 1950. In all, 2,414 families and 7,639 persons were included in the subsample. The methods of sampling and weighting the subsample to estimate an urban aggregate have been presented in other articles (2, 3). The subsample included 50 percent of the families reporting no out-of-pocket medical care expenses, 10 percent of those reporting some medical expenses but in amounts less than \$200, 20 percent of those reporting \$200 to \$400, 50 percent of those reporting \$400 to \$1,000, and all families reporting medical expenditures of \$1,000 or more (see table 1).

Totals for each of the medical care expense classes were weighted to adjust for the subsample size within each of the nine geographic regions used by the Bureau of Labor Statistics for its sample weights. Each of the nine regions in turn was then weighted in accordance with the relative population of these regions as estimated by the Bureau of Labor Statistics.

Definition of Free Care

The Bureau of Labor Statistics interview included the following questions as part of its section on medical and personal care: Did any family member receive medical care free in 1950? If yes, about how much was it worth?

In the interview, information was asked

Dr. Mushkin is an economist and Miss Crowther is a research analyst; both are in the Division of Public Health Methods, Public Health Service.

New PASB Appointments

Dr. Abraham Horwitz of Chile has been elected director of the Pan American Sanitary Bureau, regional office of the World Health Organization, succeeding Dr. Fred L. Soper, who will end his third term January 31, 1958.

The vote was taken October 1, 1958, in San Juan, Puerto Rico, at the Pan American Sanitary Conference, which is also the regional meeting for WHO members in this hemisphere. Dr. Horwitz's name will be presented to the WHO Executive Board in January 1959 for appointment.

The director-elect, who is on leave from his post as director of the School of Public Health of the University of Chile, is currently serving as assistant director of that country's National Health Service. He has been PASB consultant in training and education to various countries in the Americas. From 1952 to 1953 he was chief of the professional education branch at the regional office headquarters.

Dr. Horwitz received his doctorate of medicine from the University of Chile in 1936 and a master's degree in public health from Johns Hopkins University.

Harold R. Shipman has been appointed chief of the Pan American Sanitary Bureau's Branch of Environmental Sanitation.

Since he joined the World Health Organization's staff in 1952, Mr. Shipman has served in Turkey, Egypt, Austria, and the Americas. Previously, he was a sanitary engineer with the Minnesota Department of Health, the Farm Security Administration of the U. S. Department of Agriculture, and the American Red Cross in Korea.

Mr. Shipman holds a bachelor of science degree in chemical engineering and bacteriology and a master of science degree in sanitary engineering from the University of Minnesota. He is the author of various publications on sanitary engineering and is considered an authority on water supply and sewage disposal.

Veterans Administration hospitals and Public Health Service hospitals, (b) through research programs, (c) under workmen's compensation, (d) under arrangements paid by casualty insurance, such as automobile liability insurance, and (e) under public assistance programs.

The proportion of free hospital care indicated by the 1950 consumer expenditures survey is similar to findings of the Health Information Foundation. In its 1952-53 household survey, the foundation found that 1 or 2 percent of all families received only free hospital services (5).

The most frequent type of service received without charge was physician care. Of those reporting free service, 4 out of each 10 reported physician services outside of hospitals. Included among these services are those provided by physicians for members of their families, other relatives, employees, professional colleagues, and patients unable to pay, services in outpatient departments of hospitals, industrial implant medical services, and services provided for workmen's compensation cases. The persons reporting such services represented about 3 percent of the urban population, or about 3 million people.

Services received from physicians on hospital staffs were in many cases included within free "hospital care." There were many instances of hospitalization in which the information reported in the interview did not show out-of-pocket expenses for physician services, insurance benefits received, or free physician care. Many of those reporting care in veterans hospitals and military hospitals, for example, did not report free physician services.

Table 1. Number of persons reporting free care in Public Health Service subsample of Bureau of Labor Statistics interview schedules, 1950

No report.....	10.6	10.6

In other instances, the families reported free physician services along with hospital care. The information was tabulated attributing physician services uniformly to those urban residents reporting free hospitalization, if the information did not otherwise indicate the purchase of physician services. If the multiple entries are counted in this way, almost 6 of each 10 persons reporting free services received free physician care, including, in this instance, free care provided by physicians on staffs of hospitals.

Moreover, for those persons reporting multiple types of free services, a single, major type was selected according to the relative importance of the service. Entries reporting free "hospital care," for example, were counted only as a free hospital service even though other types of care were also noted. Similarly, if the respondent reported free physician care outside of a hospital and also free X-ray, drugs, or other services the care was classified as free physician care. The order of the classification of entries corresponds to the arrangement in table 2.

Table 3 shows a distribution of the sources of free care. Each type of source, when multiple aid was reported, and the major source, as listed, are included.

A large proportion of the respondents, some 28 percent of those reporting free care, did not report the source of free care received. Of

about each member of the family. The interviewers were instructed, with regard to these questions, that free medical care "is available in many cities in public and private clinics and health centers. Free chest X-rays are given by the Public Health Service. In addition, many employers have a doctor on their staff who provides medical care to employees at no charge. It may be difficult for a respondent to estimate the value of such service but ask him to give you his best guess, and to describe in detail what he received. Write your description of the services received in a footnote. Do not include medical care received because a family member is covered by a prepayment plan" (4).

Information on types of free care and their sources is taken from the interviewers' notes as recorded on the interviews. The classifications set forth in tables 2 and 3 are means of grouping the entries and are not part of the original questions.

As the instructions to the enumerators suggest, benefits paid by health insurance plans, including insurance financed in whole or in part by employer contributions, are excluded from free care. However, other types of insurance benefits and medical services recorded as free care by the interviewers were included: (a) automobile and other casualty insurance received as a result of an accident, (b) workmen's compensation medical services and inplant medical services, and (c) medical services in union health facilities and in special railroad hospitals. Other types of free care included care provided in public hospitals or financed under public programs such as public assistance programs, care financed by private welfare, health, and religious agencies and hospitals, and care provided without charge by members of a health profession as a matter of professional courtesy or as charity. The entries on free care appear to exclude medical services received at less than full rates, for example, reduced hospital charges.

There seemed to be some instances in which respondents interpreted free care as care paid for by a relative or friend. We excluded these entries from free care and from the tabulations presented here. Because the value of services was only roughly guessed no attempt was made to tabulate responses on that score. However,

the Bureau of Labor Statistics has tabulated these value items as part of the value of free items received for all goods and services. The amount of free medical care, according to an unpublished report of BLS, averaged \$19 for all urban families, including families who reported no free care, and \$123 for the 15.4 per cent of families reporting some free medical care.

Limitations of Data

The Bureau of Labor Statistics study was designed to provide benchmark data on cost of living of urban families. Items of information on the interview that were not related specifically to the consumer price index were not defined as carefully nor edited as thoroughly as other items.

The supplementary nature of the question on free care suggests that interviewers did not seek or obtain detailed and uniform answers. Different respondents may have interpreted the question differently. There are patent differences in the completeness of information obtained by interviewers.

Our findings necessarily reflect the definition of free care used by the Bureau of Labor Statistics, the errors in reporting information, in sampling, and in estimating the aggregates, and the under-reporting of types of free services such as chest X-rays and school health services. In interpreting these findings, furthermore, the small sample size (table 1) must be borne in mind.

Type and Source of Free Care

Urban families reported receipt of a wide range of services free of charge (table 2). These included physician services, hospital care, nursing care, dental services, laboratory tests, immunizations, X-rays, and drugs.

Free hospital services were obtained by 2 in each 10 of those reporting free services, a proportion representing about 1.5 percent of the urban population and almost 12 percent of those reporting hospitalization during the year. This proportion includes persons who reported care without charge (a) in State and local public hospitals and in Federal hospitals, including

with employment. For example, medical care under workmen's compensation, under union and employer plans, and under Government programs (such as the program for merchant seamen and for members of the armed services) is available only to those attached to a work force. Income levels of those receiving such care are related to the earnings in these employments.

The nurse receiving care in the hospital and the relative of a physician or dentist receiving care through his office illustrate another category of care which is not related to low family come.

Medical Expense Differentials

Are free services received primarily by individuals who have no expenses or small out-of-pocket expenses for medical services? Of the urban population as a whole, 17.4 percent reported no out-of-pocket expenses for medical care during 1950, whereas 1.3 percent reported no out-of-pocket spending along with free care. About 48 percent of the urban population reported medical expenditures of \$1 to \$49; 3.6 percent reported medical expenses of \$1 to \$49 with free care (table 6). Or stated somewhat differently, there is a curvilinear relationship

Table 5. Distribution of urban residents and of urban residents reporting free care, by family income after taxes, 1950

\$300-\$499-----	2. 1	. 1	5. 6
\$500 and over-----	1. 2	. 1	9. 0

between receipt of free medical care and size of out-of-pocket medical expenses.

Of urban residents reporting no out-of-pocket expenses, 7.6 percent indicated they received free care; 7.4 percent of those reporting expenses from \$1 to \$49 reported free care. The percentage of persons reporting free care is lower than average for each of the medical expense classes from \$50 to \$500 of out-of-pocket expenses. Of those spending \$500 and over for medical care, however, 9 percent reported some free care. This finding suggests the need to explore such questions as how private spending for medical care is supplemented by free services, through what agencies and arrangements individuals with expensive illnesses gain access to free services, and whether there are barriers to such access which necessitate large out-of-pocket family spending before free care can be received.

In general, our purpose here has been to stimulate interest in the distribution of free medical care among groups differing in age, income, and medical expense, and to encourage further study.

REFERENCES

- (1) U. S. President's Commission on the Health Needs of the Nation: Building America's health; a report to the President. Vol. 4. Financing a health program for America. Washington, D. C., U. S. Government Printing Office, 1953, p. 151.

those reporting free care, approximately 13 percent received services as professional courtesy or as charity; another 13 percent received care through public assistance agencies; and for 14 percent services were paid for by employers. Included in the last are implant medical services, services in connection with workmen's compensation cases, and employer arrangements other than health insurance. As indicated earlier, reporting instructions explicitly excluded services received under health insurance plans toward which the employer contributed all or part of the premium.

Free hospital care was financed by public assistance or by Federal agencies for more than half of those reporting free hospitalization.

Age and Income Differentials

The proportion of persons reporting free care varied by age group (table 4). Free care was reported for only 4 percent of the children under 6 years living in urban households. In contrast, 8.8 percent of those 19-44 years of age reported receiving free care. The percentage of persons 65 to 74 years of age reporting free care was less than the average for all age groups; however, the proportion of those 75 years of age and over was about the same as the average for all age groups.

In view of the volume of care provided for children through schools, clinics, and public

Table 3. Percentage distribution of urban residents reporting free medical care and free hospital care, by source of care, 1950

health departments, it would appear that free care for children, especially those under 6 years of age, is under-reported.

Tests of income and means applied in the administration of many public programs as well as programs of voluntary welfare and health agencies suggest that persons receiving services provided without charge are primarily in low-income families. Our findings indicate no great concentration of free services in low-income families. Those with relatively high family incomes also received free medical care. Approximately 18 percent of the persons reporting free care were in families with incomes of less than \$2,000 per year; about 12 percent of all urban residents in 1950 were in families with incomes below \$2,000. At the other end of the income scale, about 5 percent of those receiving free care were in families with incomes of \$7,500 or more, whereas 7.6 percent of all urban residents in 1950 were in families with that income (table 5).

A larger percentage of urban residents in families with incomes under \$2,000 reported free medical care than those with higher incomes. The percentage of persons reporting free medical care decreases until the income level reaches \$4,000 to \$4,999 and then tends to increase except for the highest income level. This pattern of receipt of free medical services by income classes may reflect differences in types of free medical services available in the community. While free care contingent on need is available through public programs such as public assistance programs and State and local public hospitals and through veterans' benefits for non-service-connected disabilities, there are other types of medical care programs under which eligibility is connected

Gerontology

DISCUSSION GROUP

The following are authors' abstracts of presentations to the gerontology discussion group at the National Institutes of Health, Public Health Service, during the first 6 months of 1958.

The planning of this series originated in the gerontology discussion group at the National Institutes of Health. In 1954 a group of about 20 staff members from various fields at the Institutes decided to meet once a month for informal discussion of some selected aspect of gerontology. The meetings have continued to this date with a de-emphasis on formality. The first chairman was Dr. Paul Stevenson of the National Institute of Mental Health, who served, until his retirement at the beginning of 1955, in arranging for speakers in response to suggestions of the group and of scheduling the meetings at appropriate times. In 1957, the discussion group was sponsored by the newly formed Center for Aging Research, under the direction of Dr. G. Halsey Hunt, to encourage the free exchange of information on aging.

Apart from the specific content of the presentations, other facts have emerged about gerontology in this 4-year period. Interests are clustered about certain foci: the molecular level; the general biology of the whole organism; the disease processes; the psychological aspects of aging; and the sociological or societal aspects. These seemed to be the respective interests of the gerontologists themselves at the lectures. It also became apparent in the discussions that it is impossible to compress gerontology into the confines of a single discipline, profession, or dogma.

—JAMES E. BIRREN, PH.D., CHAIRMAN, *chief of Section on Aging, National Institute of Mental Health, Public Health Service.*

Age Changes in Cells

When an animal grows old, cells in various parts of the body deteriorate so that they are no longer able to fulfill their various functions as efficiently as they did when the animal was younger. Why is this true? We should like very much to find out, for if we knew perhaps we could find some way of delaying the aging process.

For many years, cytologists have tried to discover in what ways an aging cell differs from a young cell. The results of their painstaking studies have not been impressive, and even though an occasional morphological change has been described, we know nothing about the why and wherefore of such change. Perhaps the main reason is that cytologists, both those using ordinary light microscopes and those using electron microscopes, have compared the appear-

Specialized Training Courses in Environmental Health

The following courses are scheduled for January and February 1959 by the Robert A. Taft Sanitary Engineering Center in Cincinnati, Ohio:

January 12-23. Basic Radiological Health. Fundamental technical knowledge needed for radiological health work, with stress on basic nuclear physics and chemistry. Prerequisite for several other courses.

January 12-16. Chemical Microscopy for Analysis of Air Pollutants. Emphasizes the applicability of techniques of chemical microscopy, conventional and polarized, to qualitative and quantitative identification of atmospheric particulates.

January 26-30. Radioactive Pollutants in Air. Intensive training for professional persons concerned with radioactive contamination of the air. Laboratory practice, using commercially available sampling and monitoring instruments, comprises about half of the course.

January 26-30. Sanitary Bacteriology of Water. Extensive coverage of bacteriological examination of water, including the most probable numbers methods and the membrane filter method.

February 2-6. Microbiological and Chemical Examination of Milk and Dairy Products.

Theory, laboratory techniques, and interpretation of tests used in evaluating the sanitary quality of milk and dairy products.

February 9-13. Laboratory Methods for Prevention and Control of Foodborne Disease. Methods, standards, and operating procedures for a food sanitation program. Demonstrations and laboratory exercises include microbiological and chemical methods for food quality control, and procedures for enumeration, isolation, and identification of food poisoning bacteria.

February 9-20. Community Air Pollution. Broad, technical coverage of air pollution including the roles of the community, State, Federal Government, and industry, and ordinances and legislation.

February 16-20. Radioactive Pollutants in Water. Intensive training for water supply and pollution control officials concerned with the radioactive contamination of water. Prior completion of the basic radiological health course is desirable.

Address applications to the Chief, Training Program, Robert A. Taft Sanitary Engineering Center, Public Health Service, 4676 Columbia Parkway, Cincinnati 26, Ohio, or the medical director in a regional office.

through old age. In an early study on the adult worker honey bee, the brain (like that of mammals, including humans) showed a slow but steady fall in number of the original cells from the first day of adult life to a total loss of 35 percent of that number by extreme old age. In the honey bee, enzyme studies of the brain (cholinesterase) and of muscle (phosphatases) related to energy buildup and release failed to show any corresponding changes with age. However, the quantitative relationships among these enzyme systems appear to be concerned with development and maintenance of flight ability, which is well developed in advanced old age. In the male housefly, on the other hand, which loses its ability to fly by the 10th day of adulthood, the wings are frayed, and both the acid phosphatase and the magnesium-activated adenosinetriphosphatase show pronounced drops in activity to a minimum by the 10th day.

During the course of this biochemical study, moreover, it became apparent that male houseflies had a considerably shorter average as well as shorter maximum longevity. By a series of studies involving constant humidity, temperature, and conditions of maintenance and rearing, longevities of male and female flies were compared in offspring from hundreds of generations of breeding of a standard laboratory strain of houseflies. Data accumulated for more than 4,000 pairs of flies of both sexes confirm the presence of an aging factor in the male which results in a longevity that is almost 70 percent higher for the female than the male. Experiments with reduced and enriched diet for the aging adult show that the average longevity of the male is not altered by such dietary variations; the female longevity, on the other hand, can be increased by inclusion of powdered whole milk in a sugar and water diet fed to the aging adult.

In a current study, the possible presence of a "Lansing" factor in the aging of houseflies is being investigated. Eggs, usually collected at a very young parental age, were collected at later and later parental ages; offspring from these collections were isolated and allowed to age under controlled conditions of temperature, humidity, and complete diet. First results

clearly indicate that longevity of the male offspring is the same, regardless of the parental age at which the egg has been laid. In the case of the female offspring, after the sixth day of adult life, the older the parents at oviposition, the shorter the average longevity of the offspring. The 30-day mortality of female offspring hatched from eggs collected from parents 27 days old, for example, was 90 percent, exactly equal to that of males from eggs laid at all ages. A mortality of 50 percent was found for female offspring of young parents, on the other hand.

Thus, for the housefly, it appears that there is a relatively immutable aging factor in the male as opposed to an aging or longevity factor in the female which is labile to the extent that a limited diet as well as advanced parental age at the time of oviposition markedly reduces the average and maximum longevities of such females.

Studies are being continued on the relative roles of the male and female parents in the curtailment of the longevity of female offspring hatched from eggs collected at an advanced parental age.

—MORRIS ROCKSTEIN, PH.D., *associate professor of physiology, New York University College of Medicine, New York City.*

Aging and Longevity in Rats Under Favorable Conditions

In 1945, a special rat colony for research on aging and longevity was set up in an old building at the Columbia-Presbyterian Medical Center. We attempted to produce conditions as ideal as possible in the belief that, for satisfactory results, the colony had to be maintained under uniform conditions for a long period, with freedom from noise and other disturbances and with the elimination of infectious diseases.

To this end, we installed an air conditioning system with temperature and humidity control. We adopted a uniform diet, which has been used for the last 13 years. All outside light was closed off. Indirect fluorescent lights were installed on a time switch to give 12 hours of light

ance of dead old cells with the appearance of dead young cells. And the methods used in killing cells so that they may be sectioned and stained could easily destroy any evidence of age changes in the protoplasm.

Physically, the cell is a colloidal engine, and it is proper to look for changes in the colloids of which this engine is composed. In order to appreciate the types of changes that may occur, we need to know the nature of the protoplasmic colloid. The work of many years has shown that the interior protoplasm in the cell is fluid surrounded by a stiff cortex.

This protoplasmic fluid does not behave like an ordinary protein or an admixture of such protein and lipid; it is strangely sensitive and can suddenly change from a fluid (sol) state to a more or less stiff gel. This reaction is similar to that occurring when the blood of vertebrates clots. The reaction is dependent on the presence of calcium and also on the activation of a clotting, proteolytic enzyme. Work on the nature and reactions of the protoplasmic colloid has been summarized in two books by the author, the *Dynamics of Living Protoplasm*, published in 1956, and the *Viscosity of Protoplasm*, which appeared in 1958.

According to E. Gunther's article in *Protoplasma* in 1957, when plant cells age the outer cortical layer becomes less rigid and the interior protoplasm becomes decidedly more viscous. This is exactly what I found in 1956 for aging egg cells of the marine worm *Chaetopterus*, as reported in *Protoplasma*. The loss of rigidity in the cortex of a cell is generally due to a loss of calcium from this region. The cortex normally behaves as a semipermeable membrane and offers resistance to the passage of ions into a cell. As is well known, the permeability of a cell membrane increases as the presence of calcium in it declines; as the cortex loses calcium, the cell becomes more permeable to calcium ions. The result is that calcium enters aging cells more readily than it does young cells. This is presumably why so many aged cells and tissues have been found to have a higher calcium content than young ones.

Because the protoplasm in the cell interior is so sensitive to calcium, entrance of calcium in increased amounts can cause a clotting re-

action, as already noted. For this reason old cells may show increased viscosity of their interior protoplasm or may even become vacuolated, for pronounced clotting often causes vacuolization. Moreover, aging cells tend to suck more and more calcium out of the blood; this tends to lower the calcium content of the blood. Such a lowering of calcium concentration in the blood is known to result in a loss of calcium from the bones, hence the diseases of osteoporosis and osteomalacia, so common in old people.

Naturally, we are far more interested in the age changes that occur in higher animals than in those in plants or in the egg cells of invertebrates. Recently an attempt has been made to study the colloidal changes that occur in the course of the aging process in the cells of cats. Such studies are far more difficult to make and various technical difficulties have to be overcome. However, it is possible to study living muscle fibers of kittens and mature cats, and such studies have commenced. Also attempts are being made to study the colloidal properties of liver cells from cats of various ages.

Aging in Insects

Although not a guarantee of expected results, the wise choice of a suitable animal for laboratory research may often prove to be the basis for the slim margin of difference between success and failure of an experiment.

For studies in aging, members of the largest of all animal phyla, the Arthropoda, appear to be ideal because of their small size, low cost of maintenance, relatively small space requirements for large numbers of animals, and high reproductive potential. Most of all this high reproductive potential is linked to a relatively short life history, as few as 29 days on the average for female houseflies (17.4 for males) and 33 days for adult worker honey bees.

These two species of insects have been the subjects of structural, biochemical, and biological studies from the moment of emergence

who do, not all are equally afflicted; many who receive good care may require it less than some who receive little or none.

Where psychotherapy is regarded as a luxury, psychiatric disorders will not be identified; where the needs for physical care remain unrecognized because of socioeconomic circumstances, frank illness and associated emotional disturbance may pass for physiological decline. If we are to provide services for aged persons to match their real needs for medical care by present-day standards, the way inequalities in the distribution or receipt of care come about must be studied, especially where governmental or charitable agencies are instrumental in providing these benefits. A knowledge of the characteristics of persons now receiving different types or gradations of socio-medical treatment may permit inference or clarification of how they were selected for care or suggest preventive measures.

As part of a preliminary survey for the New York State Department of Mental Hygiene, more than 600 persons 65 years of age or over selected at random from nursing homes, old-age homes, and State hospitals were examined for comparison of their physical and mental functioning. The nursing home population was in the poorest condition from the point of view of physical function, while persons in the homes for the aged functioned best. Those in State hospitals were intermediate. About 40 percent of the aged first admissions to a hospital who survived the first 3 months required active medical care. New admissions to the State hospitals were in the poorest physical condition of all. Aged persons readmitted to the State hospitals for disorders developed in early years were generally in good physical condition.

Advanced age and physical disability tended to go hand in hand in State hospitals and in homes for the aged; nursing home residents showed the same degree of disability at all ages. Persons beyond the age of 75 appeared to have physical disability with equal frequency in all institutions. Patients in the best physical condition did best on tests of mental status as indicated by comparison of the institutional population.

Two hundred and ninety-three subjects 65

years and older selected on a random basis from the variety of nursing and old-age homes were tested by M. Pollack and R. Kahn for the capacity to perceive properly simultaneous tactile stimuli to the face and hand. About half of the subjects made persistent errors. The results exactly paralleled those of questionnaire examinations for mental status. The defects in perception were found in increasing numbers with advancing age and decreasing function but preponderantly in persons where early formal education was absent or scant.

The institutions studied were relatively homogeneous both as to the background of their residents and to the general level of alertness of the residents. There are apparently interpenetrating factors of selection which create an institutional milieu. Furthermore, these factors have a continued influence in maintaining the cultural milieu. The residents contribute to a culture which in turn acts upon them for better or worse. In this way, up to a point, the good institutions probably grow better and the poor grow worse.

The findings imply that disorders of perception related to disorientation and mental disorder in the aged are strongly influenced by cultural background and also are related to physical functional capacity. In our society good early education may act as a protection against decline of mental and physical functioning in the later years; it may help to provide special protective devices for oneself; or it may be an index for correlated protective factors. In all likelihood all these possibilities are true. The sequence may be: poor education contributes to socioeconomic deprivation, socioeconomic deprivation contributes to illness, illness to invalidism or impairment of function, impairment of function to mental disturbance, mental disturbance to disability or invalidism, and invalidism to socioeconomic deprivation.

Studies of this nature appear doomed to uncover the banal, but the manner in which the obvious is uncovered may suggest practical measures for prophylaxis and treatment. By inference, a large number of the mental disorders of the aged can be traced to economic and health problems of their preceding years. Good socioeconomic circumstances, good education

and 12 hours of darkness each 24 hours, and special cages and shelves were designed for our purposes. In addition, we have endeavored to avoid unnecessary noises and rough handling.

Our stock of animals came originally from the Sprague-Dawley Laboratories. From these original animals we have bred our own with 2 closed lines of random-bred animals and 2 lines of brother-sister meetings.

In the beginning, as in other rat colonies, there was a high incidence of respiratory disease, which now has practically been eliminated. This was done by Dr. Benjamin N. Berg, who destroyed all obviously infected animals and all suspected of having respiratory infection, as well as those which failed to gain weight in a normal manner. Thereafter, with a colony nearly free from respiratory disease, we have been able to study the onset of lesions of other diseases without the complication of pulmonary infection.

As our animals become older and reach a moribund state, they are killed and given complete autopsies. The data obtained are carefully tabulated so that we have been able to determine the relationship between age and the onset of lesions of various types and to study the development of these lesions from early to severe stages.

We have recently published a study of the data on five major diseases in male rats (Simms and Berg, in the *Journal of Gerontology* 12: 244-252, 1957). Findings show that for each of these diseases the onset of the early lesion gives a sigmoid curve when plotted against age, but the shape of the sigmoid curve depends upon the type of lesion. For example, myocardial degeneration has a relatively flat curve. This disease is first seen in some of the animals as early as 200 days of age, but a period of 900 more days elapses before the curve levels off with no further incidence. On the other hand, degeneration of voluntary muscle is not seen until 550 days of age, but the curve rises so sharply that there is a 100 percent incidence after only 550 more days.

With some diseases, such as periarteritis, only a portion of the animals are susceptible. The remainder are apparently immune to this disease, with the result that the sigmoid curve levels off at 60 percent incidence. Similarly,

adenoma of the pituitary is found in less than 25 percent of the older animals, but all those susceptible acquire this tumor before 900 days.

The logarithmic increase in the human death rate with advancing age, first reported by Gompertz in 1825, has been a matter of concern for many years. The reason for the logarithmic increase has not previously been explained. Our data on rats show that their mortality follows a similar but very much steeper logarithmic curve. We have been able to show that this is not due to a change with age in the duration of the diseases from early to late stages but rather because the mortality parallels the onset of the major diseases that contribute to the death of these animals. As was stated above, the onset of these major diseases has a typical sigmoid curve. We have found, furthermore, that the probability of onset of new lesions of each disease when plotted against age gives a curve with a definite peak suggestive of a normal distribution curve. In other words, for each disease there is an age of maximum probability of acquiring a new lesion of this disease, and the resulting mortality follows a logarithmic curve, like the human mortality curves with which we are familiar.

—HENRY S. SIMMS, PH.D., *Columbia University College of Physicians and Surgeons, New York City.* (This study was carried out on grants from the Josiah Macy, Jr. Foundation and the Albert and Mary Lasker Foundation, and grant H-945 from the Public Health Service.)

Evaluation and Treatment of Older Persons in Need of Psychiatric Care in a Metropolitan Area

By current standards, mental disorder is common, and emotional ills, by some definition, affect everyone. However, circumstances often dictate that treatment be reserved for disturbed and disturbing persons who need specialized care for their welfare or that of society. Even for them there may be limited resources. Obviously, not all psychiatrically ill older persons reach points of medical care. Of those

jects to acquire the conditioned eyeblink response. Of the 13 subjects in this group, 4 subjects gave no conditioned responses during the 80 conditioning trials, 7 gave from 1 to 8, while 37 and 75 were given by the other 2 subjects. There were no instances of failure to condition in the two younger groups. This result confirms the report of Gakkel and Zinina although their study does not include data on the conditioning performance of younger subjects. To account for the failure of older subjects to condition, Gakkel and Zinina quote Pavlov as concluding that "liveliness of the nerve processes suffer(s) from the development of senile changes." They also invoke the construct of inertia of the stimulating process at senile age.

These results suggest the consideration of an adaptation hypothesis to account for the relative unconditionability of elder subjects. It is known that subjects who were adapted to the UCS (air puff) showed a significantly lower level of conditioned eyelid responses than subjects who were not given pre-adaptation trials. It is proposed that in the course of many years of living the eyelid response and probably other responses have been "adapted out" and thus are less susceptible to subsequent conditioning. Research is underway to study several consequences of this hypothesis: that both frequency and amplitude of blink are reduced as a function of age. The procedures employed in the present study did not provide data on these variables.

—HARRY W. BRAUN, PH.D., *professor of psychology, University of Pittsburgh. (This investigation was supported in part by research grant M-1365 from the National Institute of Mental Health, Public Health Service. Richard Geiselschardt assisted in the study.)*

Cornell Longitudinal Study on Occupational Retirement

The Cornell study of occupational retirement is a longitudinal study of a panel of subjects, most of whom were born in 1887, 1888, or 1889. Currently, there are approximately 2,400 participants in this study; they do not constitute a

representative sample in a statistical sense, but represent widely divergent backgrounds and all the geographic regions of the country, although the major concentration is from the more heavily industrialized sections. With the exception of a disproportionate number of professionals, the participants approximate the total male employed population from age 60 to 64. The investigators consider the population to represent the "normal aged."

In this preliminary analysis of findings from the study, the major independent variable is occupational status or the change in that status from worker to retiree. The dependent variables, adjustment, subjective health, and economic deprivation, approximate the Guttman scalar pattern. Emphasis is upon the incidence of changes among the persons who retire and those who continue in gainful employment.

Our data have not supported the hypothesis that, in general, retirement leads to a decline in adjustment. We have found that continued employment for some older persons may result in a decline in certain measures of adjustment equal to or greater than changes experienced by persons who retire. This general finding was confirmed by data from the two periods under analysis: 1952-54 and 1954-56.

Age identification as a measure of adjustment was also examined; the data suggest clearly that retirement does not result in a deterioration in age identification. The retired are no more likely to experience a decline in age identification than the gainfully employed.

We also examined the data on the relationship between the forms of retirement and adjustment and we noted that a person's attitude before retirement is a more influential factor affecting a person's adjustment than the circumstances surrounding retirement, that is, whether the decision was made by the person himself or his employer. Persons who have negative attitudes toward retirement are more likely to evidence inadequate adjustment in retirement than are those with positive attitudes before retirement.

By means of the longitudinal analysis, it was shown that the association between retirement and health is largely explained by the fact that people in poor health tend to retire and not that retirement affects health negatively. This

early in life, and the protection of physical health through the provision of social, public health, and general medical services promise to decrease the number of disoriented aged persons and the intensity of their disorders in the future. For those now ill, social rehabilitation techniques and good general medical treatment may mean the reclamation of a number of disoriented and maladjusted aged persons. Mutually damaging reciprocating relationships of person and institution should be interrupted; at times this requires no more than provision of the very important service for the protection of mental health: good medical care.

Age Differences in the Acquisition and Extinction of Conditioned Eyelid Responses

The eyeblink is difficult to condition in persons over 65 years of age, but when conditioned, is more resistant to extinction, according to a report by L. B. Gakkel and N. V. Zinina in the *Fiziologicheskii Zhurnal* (Moscow) in 1953. This report stimulated a study to provide systematic information on eyeblink conditioning and extinction among children and young and old adults under the same controlled conditions.

The subjects were 15 boys in the age range 8–10 years, with a mean age of 9.36 years; 15 young men aged 18–25 years (mean age 20.63 years); and 13 men aged 62–84 years (mean age 70.5 years). The old adults were noninstitutionalized and were either employed full time or part time or were retired.

The conditioned stimulus (CS) was an increase in the brightness of a 6-cm. circular milk glass disk from 1 to 1.5 apparent foot-candles. The duration of the CS on each trial was 1 second. The unconditioned stimulus (UCS) was a puff of air with an intensity of 2 pounds per square inch delivered to the right eye, with a duration of 500 milliseconds. All subjects were given 80 conditioning trials. Intertrial intervals were spaced at 10, 15, and 20 seconds ac-

cording to a prearranged schedule. Following the 80th conditioning trial, 20 extinction trials were given in which the CS–UCS interval was lengthened to 1,500 milliseconds. Subjects were tested in a dark and relatively quiet room. The equipment for recording eyeblinks and presenting the CS and UCS was similar to that of K. W. Spence described in the *Journal of Experimental Psychology* in 1953.

Through the 60th conditioning trial, the conditioning curve for the children was consistently above that of the young adults, and it was above that of the elderly group throughout the entire 80 trials. The conditioning performance of the young and old adults was similar through the first 20 trials after which the young group improved markedly and the elderly group only slightly. The conditioning curve of the children was negatively accelerated, that of the young adult group was positively accelerated, while the curve of the old adults was flat. At the start of conditioning, either the performance level of the children or the rate of conditioning was relatively high or both were high. On the other hand, the performance level of the other two age groups at the beginning of conditioning was relatively low or the rate of conditioning was slow or both conditions prevailed.

Statistical evaluation of these results was made by the Mann-Whitney test. The difference between the number of conditioned responses made by the children and the old adults was significant beyond the .002 level of confidence for a two-tailed test ($U=23$). The difference between the number of conditioned responses made by the young adults and the old adults was also significant beyond the same level of confidence ($U=25$). The children and young adults did not differ significantly in the number of conditioned responses ($U=89$).

Resistance to extinction was also inversely related to age. The use of the Mann-Whitney test showed that the children made significantly more conditioned responses during extinction than the elderly adults ($U=27$; $P<.002$) as did the young adults ($U=49$, $P<.05$). The two younger groups did not differ significantly in this respect.

The main and striking finding of this study was the relative inability of the elderly sub-

Public Health and Medicine

exhibit

Brussels World Fair

J STEWART HUNTER

AN EXHIBIT on public health and medicine in the United States was on display at the Brussels World Fair between August 18 and October 19, 1958. Housed in three buildings adjacent to the main American Pavilion, the exhibit was designed and built by the Public Health Service.

Mr. Hunter is Assistant to the Surgeon General for Information, Public Health Service. Mr. Hunter, William Thompson, assistant chief, Visual Aids Branch, Department of Health, Education, and Welfare, and Harry Wiener, visual information officer, Bureau of State Services, Public Health Service, formed the three-man team who conceived and built the exhibit in Brussels after some preliminary planning in the United States.

Its purpose was to tell the story of progress in American health during the past several decades with some emphasis, as well, on the unfinished tasks that lie ahead.

A display on American health was considered important for several reasons:

First, how a nation provides for the health of its people is a significant gauge of how that nation lives. In Dr. Howard Rusk's phrase, "The emphasis we place on dignity and service for our sick and handicapped is [also] a hallmark of life in America."

Second, the story of American accomplishments in health is exportable. Health techniques, methods, knowledge, and facilities developed in the United States are now being used in many parts of the world. We are al-

part of the analysis is based primarily upon self-appraisals of health; but the findings are substantiated by the analysis of objective changes in health, that is, ratings by examining physicians. As in other studies, we do find a higher incidence of relatively poor health among persons who have retired, but it would seem that this correlation can be understood in terms of poor health leading to retirement and not the reverse.

One of the most obvious and objective effects of retirement is economic, for it is the rare retiree who is able to maintain his preretirement income. However, it seems agreed by a number of students of retirement that objective income must be interpreted in terms of the needs and wants of the persons. The researcher studying retirement must be aware of the subjective aspects of income. In the Cornell study we developed a measure of what we call economic deprivation in order to determine changes in attitude regarding objective changes in economic status. The panel analysis shows clearly

that retirement contributes to the development of economic deprivation. However, the data also indicate a perhaps more striking finding: a high proportion of retirees possess a sufficient "role flexibility" that enables them to adapt to a greatly reduced income.

One general conclusion from this study, of which a fuller report appears in a forthcoming issue of the *Journal of Social Issues*, is that longitudinal surveys of retirement can point to the need for reexamining some stereotyped ideas about the effects of retirement. There appears to be a wider range of adaptability and adjustment than is commonly thought.

—GORDON F. STREIB, PH.D., *professor of sociology, Cornell University. (Initially supported by funds from the Lilly Endowment, Inc., the study now continues through grants from the National Institute of Mental Health, Public Health Service. Contributions to the analysis were made by Dr. Wayne E. Thompson, assistant professor in Cornell's sociology and anthropology department.)*

New Sections of *Excerpta Medica*

Two new sections of *Excerpta Medica*, Rehabilitation (Section 19) and Gerontology and Geriatrics (Section 20) were begun in July 1958. Each is published monthly by the Excerpta Medica Foundation.

With the objective of "opening another avenue to aid the medical professions in this 20th century challenge, the conquest of disability," the Rehabilitation Section is devoted to experimental, clinical, and program aspects. The first issue contains 314 abstracts, arranged according to a preestablished classification system to facilitate reference. Publication of this section is aided by a grant from the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare.

The new Gerontology and Geriatrics Section, aided by a grant from the Public Health Service, covers the whole field of aging and the aging process. Recognizing that the subject is of social as well as medical concern, it includes such topics as social behavior, social welfare, economics, and politics in addition to purely medical problems.

Photographs (left) illustrate hospital and medical care in the United States. Exhibit (right) traces the development of antibiotics from bread mold to the final product in the symbolic petri dish. Tree bears a quotation from Psalm 67, "The earth has yielded its increase . . ."

for each nation remains among mankind's great unfinished tasks.

This is a story of how the battle for better health is being carried on in America and something of the great challenges that lie ahead . . ."

The interior of the first building used the concept of a crumpled newspaper with headlines indicating some of our national problems in health and medicine. The nature of these problems was merely suggested by four photographs illustrating the broad fronts in the fight against illness: prevention, treatment, medical care, and control of the environment.

The second building was devoted to visual treatment of these four broad themes by specific examples which showed, not literally but impressionistically, America's accomplishments and future tasks. Throughout the accompanying text the linkage of medical science in the United States to the scientific accomplishments of other nations was indicated.

A summary of the present health status in the United States introduced the visitor to the second building. A light box containing a color photograph depicted in a series of 15-second flashing light sequences the average size of the various groups in the American family from

1900 to the present. The text pointed out that in 1900 a child at birth could expect to live 46 years; but in 1958, a child at birth can expect to live 67 years, or well into the 21st century.

Opposite the light box was a model of a beating heart, used as a symbol of health. The accompanying text pointed out that in the United States certain of mankind's ancient enemies have been conquered: malaria, typhoid fever, smallpox, diphtheria, pellagra. Others, however, remain: cancer, heart disease, arthritis, mental illness, dental diseases, and the problems of the modern environment.

The section on prevention highlighted the development of the poliomyelitis vaccine, one American story which is well known throughout much of the world. Photographs traced the story from its beginning through research, trial, application, and results. A chart showed the Nation's progress against this disease during the past 4 years. The guides were asked to point out that within weeks after the vaccine proved successful, the United States made its formula known to all the nations of the world.

The Salk vaccine story also illustrated the promise of medical research. "Medical research," an accompanying legend read, "on which the U. S. currently spends over \$400 million annually is a first line of defense. Through the work of scientists the world over, the dark mystery of cancer, the cause of heart disease, and other illnesses will one day be uncovered."

The guides pointed out that Congress, over the past 10 years, has voted increasing amounts for medical research, principally for grants to universities, medical schools, hospitals, and other research laboratories. Industry, universities, and private foundations were credited with their part in this national endeavor.

The guides were coached to emphasize the international character of research, citing the long and illustrious list of scientists from dozens of nations who have contributed to American and world progress in health. This information permitted visitors to identify themselves and their countries with the march of health.

A series of photographs under the general heading of prevention demonstrated another phase of research and its application, the use

ready contributing substantially to health throughout the world, and President Eisenhower has suggested that we seek ways to increase that contribution.

The Brussels fair presented an opportunity to tell that story. The objective, therefore, was not only to show what we do in health and how we do it, but to illustrate the enormous potential which the export of American ideas and techniques in health holds for people in other nations.

Two further points about this exhibit should be mentioned. First, exhibits are not the only nor necessarily the best method of presenting American accomplishments in health to the world. All the techniques of public education and health information could—and should—be employed if we are to do a really significant job on the world scene.

Second, the Brussels exhibit cannot be considered a prototype of exhibits abroad. For example, it was necessary to fit the story into a physical structure designed for another purpose. From mid-April until mid-July the three buildings, used ultimately for the health display, had housed an exhibit on unfinished

tasks in the United States, specifically on man in relationship to man, on man in relationship to nature, and on man in relationship to his environment. Moreover, events obliged us to design and develop most of the health exhibit on the spot within 3½ weeks.

The major problem in planning the exhibit was to encompass the tremendously varied and complex story of American health within manageable visual form. We started with several basic assumptions: (a) the story was not to be told chauvinistically but in a spirit of sensible candor which presented what has been done and what remains to be done in the United States; (b) the exhibit was to include as many elements of public health and medicine in this country as possible, rather than cover the work of a single profession, group, or institution, within or outside government; (c) because of its wide scope, the story had to be presented impressionistically rather than literally.

The decision was made, therefore, to classify health work in the United States under four broad areas of activity: prevention, treatment of the sick and disabled, medical and hospital care, and control of the environment.

To round out the story of American health which the exhibit simply outlined, we relied on a group of young American college students employed in the United States Pavilion to serve as guides, to answer questions, and to describe aspects of American life not fully pictured. These guides were thoroughly briefed and were given fact sheets which contained more detailed information than the displays included.

The theme of the entire exhibit was summed up in the opening panel of the first building:

"Better health is one of man's brightest dreams.

From the beginning, man has fought pestilence, disease, suffering, and premature death.

The face of the enemy is changing . . . from death-dealing scourges to diseases that maim and disable.

The weapons have changed . . . from nostrums to miraculous drugs and the skills of modern medicine.

The scene is changing . . . from the pace of rural life to the tempo of great cities.

But the struggle endures and better health

Outside the public health and medicine exhibit at the Brussels World Fair are Dr. Leroy E. Burney, Surgeon General of the Public Health Service, and (right) Dr. Thurston J. Davies, executive director of the American Pavilion. The panel inscription, like all signs and captions in the pavilion, is in English, French, and Flemish.

promise for mankind. They were asked, for example, to tell visitors of the successful use of antibiotics against yaws in Haiti. Similarly, it was suggested that they mention the conquest of malaria in the United States, and the worldwide malaria eradication campaign now being undertaken through the World Health Organization.

The section on care covered rehabilitation of the ill or handicapped and American progress in developing hospital and medical facilities. "Hospitals are needed for a growing population," the accompanying text read, "and for the care of the elderly whose numbers, in America as in other lands, are steadily increasing. Funds voted by the Congress of the United States or contributed by individual Americans have built thousands of hospitals in recent years. More are being built; more are needed."

In this field, the guides were briefed on the steadily rising level of medical care in America brought about by research, new drugs, new methods of surgery, improved medical and public health practice, and perhaps most important and basic to this rise, the sustained public interest in the improvement of health. They were also given information on the accomplishments of the joint Federal-State-local hospital construction program and on the health and medical care problems of an aging population.

Among a wide range of possible subjects, two—water pollution and air pollution—which are common to industrialized nations, were chosen to illustrate control of the environment.

Two brief statements accompanied the pictures: "As great cities grow, so do the hazards of environment. Pittsburgh, Pa., America's 'smoky city,' has cleaned up its air. Both air and water pollution are unfinished tasks for other cities in the U. S. and throughout the world." And, "Wastes from industrial plants and over-taxed disposal systems in growing suburban areas contribute to polluted rivers. Many thousands of streams and lakes provide good clean water. The job of restoring many other rivers is a big one—a task in which Ameri-

can industry, local communities, and the Federal Government are cooperating."

Three "before and after" photographs of Pittsburgh illustrated accomplishments in reducing air pollution. The environment section provided an opportunity for the guides to discuss briefly other subjects such as sanitation, personal hygiene, the safety of water and milk supplies, and the safety and quality of food and drugs.

The third building suggested the world toward which we are moving, a world in which the great diseases will have yielded to the impact of research, control measures, better care of the ill and the handicapped, and increasing control over the environment.

An important part of this section showed the pattern in which health services are provided to the people of the United States. It is a partnership of the many: the health professions, voluntary agencies, universities and research centers, hospitals and clinics, citizens groups, and local, State, and Federal Governments.

America's health objectives for the future were summed up in two brief panels. The first panel contained a quotation from President Eisenhower: "We shall not relax in the struggle against disease. The health of our people is the very essence of our vitality, our strength and our progress as a nation."

This statement on the importance of health, equally relevant to all nations, sums up the value that Americans place on this intimately human need.

On the opposite panel there was a statement of objectives which embodies both the domestic ideal and the concept of America's role in relationship to other nations:

"To continue, through research and improved public health and medical practice, the fight against suffering and premature death in America . . .

"To help pursue, through the World Health Organization and other means, the search for a healthier world."

The health objectives of the United States were summed up in a quotation from President Eisenhower: "We shall not relax in the struggle against disease. The health of our people is the very essence

of our vitality, our strength and our progress as a nation." The panel containing the statement in three languages was in the building devoted to health in the future.

of sodium fluoride to prevent dental caries. The fluoride story was chosen not only because it is illustrative of research applied to human health but also because of the wide prevalence of dental caries abroad and the fact that fluoridation of community water supplies is a simple, inexpensive method of cutting down measurably on such defects.

The exhibit showed the source of antibiotics, simple molds; how they are refined and mass produced; their tremendous variety; how they are administered; and the diseases against which they have been most effective.

The section on treatment, also presented in terms of accomplishment and of challenge, illustrated the story of antibiotics. For the world of science the antibiotics are a triumph of research; for the United States they are a triumph, as well, of mass production methods.

The text stated: "In 1929, a brilliant English scientist, Sir Alexander Fleming, discovered penicillin. Since then, thousands of new drugs and many new medical techniques have given hope to millions and relieved untold human suffering. As long as needless deaths occur, medicine's great challenges remain."

The guides could again point out the international character of research and its infinite

Resistance to insecticides on the part of insects of public health importance is by no means restricted to houseflies and mosquitoes; certain cockroaches, fleas, lice, and bugs are also resistant. There are now 44 species of vectors and pestiferous insects that are resistant to one or more insecticides (1). The geographic areas involved and the number and type of insecticides to which insects have become resistant are increasing steadily.

There are 26 species of resistant insects that are vectors of diseases such as malaria, yellow fever, encephalitis, diarrhea and dysentery, typhus, filariasis, dengue, and Chagas' disease. Nine species of anopheline vectors of malaria in 7 countries, including *Anopheles quadrimaculatus* in the United States, have been found resistant to one or more of the insecticides generally used in residual spraying of homes for malaria control.

The continued effectiveness of insecticides against malaria vectors is important to our ability to cope quickly with localized outbreaks of reintroduced infection and consequent possible spread of the disease. In the fight against insectborne enteric diseases, resistance in houseflies has necessitated the development of newer and more effective insecticidal measures and greater dependence on elimination of fly breeding. The rising standard of living in the United States, particularly since World War II, has been accompanied by rapid expansion in organized mosquito control programs and other types of community insect control activities. In addition, household use of insecticides in the United States has increased tremendously during this period. It is estimated that from \$75 to \$100 million is expended annually in America for chemical control of insects of public health importance. Resistance to insecticides, therefore, is an important consideration in both the effectiveness and cost of control activities.

CDC Investigations of Resistance

The Communicable Disease Center of the Public Health Service initiated laboratory and field investigations of insect resistance when the problem was first recognized. These continuing studies, conducted by the Technical De-

velopment Laboratories in Savannah, Ga., may be grouped as (a) fundamental investigations of the biological mechanism involved; (b) detection, measurement, and evaluation of the importance of insect resistance; and (c) development of remedial measures. Throughout the period of these studies, technical assistance has been given to other Federal agencies and the States.

Resistance may be defined as the ability of an insect population to withstand a toxicant to a greater degree than a normal population and to transmit this characteristic from one generation to another (2). Three types of biological mechanisms of insect resistance are generally recognized: (a) physiological mechanisms which enable insects to withstand or detoxify insecticides within their bodies, (b) morphological mechanisms which prevent a toxicant from entering the body, and (c) behavioristic mechanisms which permit changes in the insect's behavior patterns so as to avoid exposure to lethal dosages of insecticides. Studies conducted by the Communicable Disease Center have been concerned primarily with physiological and behavioristic mechanisms.

Physiological Resistance

In the CDC laboratory investigations of the physiological mechanism of resistance, strains of various insect species, principally houseflies and mosquitoes, are selected for resistance by exposure through a number of generations to a particular insecticide. Information on the mechanism of resistance then is obtained through studies of the absorption and metabolic fate of insecticides in both resistant and susceptible strains of the insect species.

Research is continuing on the physiological mechanism of resistance of houseflies to DDT and other chlorinated hydrocarbons and to certain organic phosphorus compounds. Results of these investigations have supported the finding that the cause of resistance to DDT is the conversion of DDT to DDE, a degradation product less toxic or harmless to the insect. This conversion process is effected through the action of an enzyme, DDT-dehydrochlorinase (3).

Physiological resistance in insects other than

The increasing resistance to insecticides is threatening the impressive gains in control of vectorborne diseases. The Communicable Disease Center is studying the biological mechanisms of resistance and means of detecting and counteracting this phenomenon, and is providing technical assistance for other Federal agencies and the States.

Insect Resistance to Insecticides

R. J. HAMMERSTROM

SOME of the major achievements in public health since 1944 have been realized through the use of newer insecticides, beginning with DDT. Important vectorborne diseases, such as malaria, typhus fever, yellow fever, and insectborne enteric infections, have been controlled effectively in certain parts of the world and virtually eradicated in others through the use of insecticides. In the United States, for example, malaria is considered to be near eradication; endemic typhus fever morbidity has fallen from a peak of 5,401 reported cases in 1944 to an alltime low of about 100 cases annually. These phenomenal achievements in this country and elsewhere are attributed for the most part to the use of DDT.

The development of resistance to insecticides by many important disease vectors, however, threatens the continuation and extension of worldwide progress in the control of vectorborne diseases. For this reason, insect resistance is internationally recognized by leading

health authorities as the most important problem facing organized vectorborne disease control programs today.

Worldwide Significance

Resistance of houseflies to DDT was first noted in Italy in 1946. In immediately following years, the phenomenon was reported from other countries, including the United States in 1948. Resistance of houseflies to DDT led in subsequent years to the use of related chlorinated hydrocarbon insecticides, such as methoxychlor, TDE, lindane, chlordane, heptachlor, and dieldrin, with the result that resistance to these compounds also developed. Today, housefly resistance to DDT and to other chlorinated hydrocarbons is evident in practically all countries of the world. In some areas, including the United States, houseflies are beginning to show resistance to the more recently developed organic phosphorus compounds.

Mosquitoes began to show resistance to DDT at about the same time as houseflies. The first observations of resistance were reported for *Culex pipiens*, also in Italy. Resistance to DDT and other chlorinated hydrocarbons soon became evident in a number of species of culicine and anopheline mosquitoes in many countries. As with houseflies, certain species of mosquitoes are now resistant to some organic phosphorus compounds.

Mr. Hammerstrom, formerly deputy chief of the Technology Branch, Communicable Disease Center, Public Health Service, Atlanta, Ga., is now the regional sanitary engineer, International Cooperation Administration, Department of International Health, Lima, Peru. This paper, with minor changes, was presented at the meeting of the United States-Mexico Border Public Health Association, April 8, 1958, in Juarez, Chihuahua, Mexico.

tol, and too frequently the failure to obtain control has been attributed to resistance when other factors were responsible.

A method and a kit have been recently developed for wide-scale use in detecting the presence and extent of resistance in adult mosquitoes in malaria and other control programs. Such a method, if standardized, would also provide a valuable means of measuring in the field the susceptibility levels of various species of mosquitoes. The testing apparatus is a modification of equipment developed earlier by Fay and associates (11). In general, the test procedure entails exposing adult mosquitoes to commercially prepared paper surfaces treated with formulations of DDT or dieldrin in Rissella oil. Papers selected for use in the test kits provide surfaces of 0.25 to 4 percent DDT or 0.05 to 1.6 percent dieldrin to be used at specific exposure periods. Mortality is determined following a 24-hour holding period (12). The test procedure and kits are being evaluated in the field in the United States and in other countries.

The Technical Development Laboratories make every effort to keep up to date on the occurrence of insect resistance, especially in the United States. Instances of resistance that arise in the course of CDC's studies are investigated thoroughly. The finding of malathion resistance in a strain of houseflies in the vicinity of Savannah, Ga., in 1956 has already been described. In Bolivar County, Miss., in 1955, *A. quadrimaculatus* was found to be highly resistant to dieldrin. Followup laboratory studies indicated that this strain also was highly resistant to BHC and chlordane (13). This finding represented the first detection of resistance in *A. quadrimaculatus* to chlorinated hydrocarbon insecticides in the United States.

Information on reported or suspected insect resistance is received from State health departments, mosquito abatement districts, agricultural agencies, research institutions, and other sources in this country. These reports are studied carefully with such followup inquiries as may be necessary to ascertain whether or not the resistance actually has been confirmed on the basis of experimental data. In some instances, the Technical Development Laboratories have confirmed specimens submitted

from the field. For example, laboratory studies recently have been conducted on a colonized strain of housefly against which both malathion and Diazinon became ineffective at a dairy in Phoenix, Ariz. (10). This strain had been successfully controlled with malathion from 1954 to July 1956, at which time Diazinon was substituted for malathion because of inadequate control. Effective control again was achieved until June 1957. Topical applications of malathion, Diazinon, and parathion at CDC's laboratories indicated the strain to be resistant to all three compounds.

Technical Assistance

In addition to laboratory confirmation of suspected resistance in field operations, technical assistance is available from CDC's State Aids Section to State and local health departments and other organizations concerned in determining or confirming the presence of resistance in an insect species. In the past few years, a number of such requests from States have been met. Currently used and other available insecticides have been evaluated in field operations, and changes in control measures have been recommended.

While additional knowledge on the mechanism of resistance is being gained through research, the necessity of combating the present problem requires continuing studies for the discovery and development of new and improved insecticides and methods for their use. CDC is conducting laboratory and field tests to evaluate the insecticidal activity of experimental and available commercial compounds against both susceptible and resistant strains of arthropods. Both recognized arthropod vectors of disease and those species generally regarded as pestiferous are used in such tests. Principal attention is given to insects indigenous to the United States, but resistant strains from other countries are also tested. Such tests not only determine the most effective commercial compounds but also are used in the development of new and improved insecticidal materials.

For the control of houseflies, DDT and other chlorinated hydrocarbons are being evaluated as larvicides and also as adulticides in the form of residual deposits and space sprays. Or-

houseflies also has been investigated. For example, the enzyme system involved in the degradation of DDT by DDT-resistant body lice has received some attention. The products of the metabolized DDT, however, have not yet been identified (4).

Colonization of a dieldrin-resistant strain of *A. quadrimaculatus* is underway in the laboratory, and the mechanisms of resistance to this insecticide will be studied when the resistant laboratory colony has been established.

Consideration of the subject of physiological resistance would not be complete without some mention of genetics in relation to the acquisition of resistance. It is generally recognized that more understanding of genetics is essential to explain how a population of susceptible insects can become resistant through exposure to insecticides. Limited genetic studies by CDC have included observations on the patterns of acquisition and loss of resistance in resistant houseflies. It is apparent that more than one pattern of resistance may arise from selection of a given strain and also that the pattern of resistance loss in partially reverted strains may not parallel the pattern of resistance acquisition.

Behavioristic Resistance

While changes in insect behavior patterns are recognized as a mechanism of resistance to insecticides, there have been relatively few confirmed cases of behavioristic resistance (5). The lack of a greater number of such cases is generally attributed to the paucity of studies and observations of insect behavior prior to the use of insecticides for control of the selected species involved.

Several examples of behavioristic resistance have been found in our work. As a result of reduced flight in the presence of DDT-synergist space-spray applications, resistant flies contact less spray than susceptible flies. Studies of the resting habits of flies in rural and urban areas have suggested that following exposure to residual DDT applications these insects changed their nocturnal resting places from indoors to outdoors during the warmer periods of the year (6, 7).

In 1956, both behavioristic and physiological

resistance to malathion was demonstrated in a strain of houseflies in the Savannah, Ga., area (8). This was the initial reported occurrence of resistance to malathion by houseflies in the United States. Following 12 weeks of effective control at a dairy with a malathion bait preparation (2 percent malathion at a dosage of 4 ounces of bait per 1,000 square feet of floor area), fly populations began to increase in spite of more frequent treatment and changes in types of bait formulations. Observations revealed that the flies were no longer attracted to the malathion baits, but actually appeared to be repelled by them. The majority of the flies approached the bait in flight but failed to alight on it: a true behavioristic response. Both the behavioristic and physiological types of resistance in this strain of houseflies were confirmed in subsequent laboratory and field studies (9).

In 1957, Schoof and Kilpatrick observed a similar pattern of behavioristic resistance in the Anderson strain of houseflies collected at a chicken ranch near Savannah, Ga. (10). Laboratory tests indicated that a colonized strain of this housefly was highly resistant to malathion and less susceptible to parathion and Diazinon than a standard laboratory strain.

The ecology and biology of both resistant and normal populations of vectors are important aspects of CDC's research on resistance. Studies are conducted of breeding requirements, biting and resting habits, and changes in life cycles or biotic potentials of resistant and susceptible strains. Such information is important in detecting and understanding behavioristic resistance and for developing and applying effective control measures.

Detecting and Measuring Resistance

One of the most important problems confronting those responsible for carrying out vector control programs is the early detection and measurement of resistance to insecticide in an insect species. Evidence of resistance is observed through reduced insect mortalities following the use of insecticidal formulations and application techniques which previously provided effective control. Many factors other than resistance can influence the degree of con-

Conclusion

Insect resistance to insecticides should concern all public health workers and especially those engaged in the control of vectorborne diseases. Resistance is increasing more rapidly than research can develop ways and means of preventing or combating it. In the United States, Federal agencies, universities, and private research laboratories are conducting research on insect resistance. The Communicable Disease Center will continue its research and technical assistance activities following leads from current studies as well as any new approaches that may be indicated, and it will continue to work closely with State and local public health officials and other personnel engaged in insect control activities.

With these resources and with increased support through greater recognition and appreciation of the insect resistance problem, ways will be found to protect and advance the progress that has been achieved in the control of insects of public health importance.

ganic phosphorus compounds are being studied as larvicides and as adulticides in the form of residual treatment and poisoned bait. One of the more significant developments in recent years has been the discovery of DDVP, which is being used widely in poisoned baits (14). Another valuable contribution has been the development of impregnated cords using organic phosphorus compounds, such as parathion and Diazinon, as residual insecticides for housefly control (15, 16). In the development of new and improved insecticidal formulations, attention is given to the combination of insecticides and to the use of synergists, additives, and attractants.

Similar research is being done on the use of various chlorinated hydrocarbon and organic phosphorus insecticides and methods of application for mosquito control. Here again, the objective is to develop improved formulations and techniques necessitated, in part, by resistance. In recent years, attention has been directed to pre-flood and post-flood treatment of irrigated areas for control of ricefield and other irrigation mosquitoes, residual larviciding against a variety of anopheline and culicine species, and fogging and barrier strip spraying for control of salt-marsh mosquitoes. In addition to laboratory and field investigations of improved insecticides and application techniques for the control of flies and mosquitoes, more limited studies of a similar nature are made on the control of cockroaches, fleas, and other insects.

The results of these investigations have been summarized as recommendations in CDC's annual report of public health pesticides, which for the past several years has been published in the March issue of *Pest Control*. This report, which also includes current data from the literature and unpublished data from other research organizations, is a valuable source of up-to-date information on the control of both resistant and susceptible insects of public health importance.

The growing problem of resistance has necessitated reemphasizing time-honored and proved methods of prevention and control of insect breeding through sanitation and other environmental measures. No insect has developed or ever will develop resistance to the elim-

ination of its breeding area. Consequently, more attention is and will continue to be devoted to improved sanitation practices for prevention of housefly breeding and to drainage, filling, diking, and improved water management practices as a permanent means of eliminating mosquito breeding. The Communicable Disease Center supports this philosophy and is directing much of its research and technical assistance activities to that end. Research is being conducted at Savannah, Ga., and at Chandler, Ariz., on composting as an effective means of refuse disposal. In many areas of the western United States, CDC's Encephalitis Section is investigating improved methods of water management as a basic approach to the prevention and control of mosquitoes associated with irrigation and other water resource developments. In the cooperative community vector control demonstration projects in which CDC is participating, emphasis is placed on permanent sanitation improvements, such as better refuse storage, collection, and disposal, elimination of privies, and improved sanitation of animal pens, as a means of effective vector control. Insecticides are used on these projects only as a supplemental measure and then with due regard to insect resistance.

While I have discussed primarily the CDC research and technical assistance activities in connection with insect resistance, I realize that the question naturally arises, What can a member of a State or local health department do? First of all, he can stimulate broader recognition among health authorities of the growing importance of this problem. He can become more familiar with and support research activity, not only in this country but on a global basis, to overcome or combat insect resistance. All can be alert to the reported or observed instances of resistance in local areas and make this information known to those who are interested, and that includes the Communicable Disease Center. For those who are engaged in operational programs, particularly the control of mosquitoes, available field tests should be employed to detect early resistance to effect both economy and adequacy of control. Finally, improved sanitation and other environmental measures can be applied.

The active sharing of experiences, knowledge, and ideas, each year enriching the partnership between the United States and Mexico for better health along the border, was continued this year at the 16th annual meeting of the United States-Mexico Border Public Health Association in El Paso, Tex., and Juárez, Chihuahua. From April 7 through 11, 1958, the discussions took stock of progress, drew patterns for future action, and reviewed pioneering techniques. Presiding over this year's meeting was Dr. Malcolm Merrill, director of the State of California Department of Public Health. The President-elect is Alberto Ortiz Irigoyen, director of Potable Water Construction in the Mexican Ministry of Hydraulic Resources. Summaries of selected papers presented at the meeting appear on the following pages.

International Health Aims Translated Into Action

As chairman of one session of the U. S.-Mexico Border Public Health Association meeting in El Paso, Dr. David E. Price, Assistant Surgeon General of the Public Health Service, commended the work of border cities in developing water and sewage facilities, work carried out with aid from the International Boundary and Water Commission and the Mexican Government's *Recursos Hidraulicos*. Specifically, he men-

tioned sewage facilities in Douglas, Ariz., and Agua Prieta, Sonora, and in the sister cities of Nogales.

Price also paid tribute to the Mexican Ministry of Health and Welfare for its impressive malaria eradication campaign.

Among examples of contributions to border health programs made by the Pan American Sanitary Bureau, Regional Office for the Americas of the World Health Organization, Price cited the multilingual venereal disease reporting form for international exchange of information on contacts, which is now being

adapted for domestic use throughout Mexico and the United States. Together with United States Federal, State, and local health agencies, the bureau is also seeking the optimum means of reporting tuberculosis suspects found through the border X-ray program.

Turning to activities of the United States Indian health program with bearing on border health, he sketched briefly the confused citizenship and residence pattern of the Papagos, almost all of whom have relatives and therefore frequent contacts across the border. Tra-

Women's Will

During the big dry season of 1957 in La Prosperité-Bersaba, a community of 260 persons in Surinam, the usual sources of water, rain barrels and Coropina Creek, dwindled. The soil formed a hard crust. Cassava, ananas (pineapples), bacove (eating bananas), napie (a sweet potato-like root), and gember (ginger) grew poorly. There were few crops to take to market along the railroad track, a 15-minute walk from the village, or in the town of Republiek, 30 minutes away.

Mothers of La Prosperité-Bersaba, shepherding their children to Republiek's consultatiebureau, heard how other villages were working together to get wells. The women decided to do something about their own community's plight and asked for a well.

Their request surprised the Surinaams Amerikaans Bureau Technische Samenwerking, because their village had previously been unenthusiastic about the bureau's well demonstration program. Now everyone wanted to talk to the health education assistant, the public health nursing trainees, and the sanitary inspector. They even stayed home from their kostgrond (fields) to be sure they would not miss seeing these people.

At a community meeting, they selected 3 men and 2 women to visit with the sanitary inspector to see what other villages had done. They also chose one of their most dependable citizens to supervise the voluntary crew that would work on their village well.

When the train brought the materials, everyone went to work, rolling the big concrete sections of pipe over the path to the well site, and bringing sand, gravel, and cement in wheelbarrows, baskets, and pails. Digging in the parched, sun-hardened earth was exhausting, but the well grew deep enough to insure a supply of water even in the long dry season. Several nights the work went on by lantern light.

Two weeks from the day the materials were unloaded, the well was finished. On November 1, 1957, La Prosperité-Bersaba proudly dedicated its new well.

—HILDRUS A. POINDEXTER, *chief public health officer, U. S. Operations Mission, Surinam.*

Potent Water

The well in Sunchon, Cholla Namdo Province, Korea, built with materials supplied through our sanitation program, has acquired an unexpected reputation. While I was inspecting the well soon after it was completed, a woman thanked me so effusively I wondered what had brought about such profound gratitude. I learned she had had seven daughters in succession, but after drinking water from the new well had given birth to her first son, to the delight of her family and the entire community.

—WALDO E. SMITH, *sanitation adviser, U. S. Operations Mission, Korea.*

Urban Improvement

A local sanitary inspector stimulated the cleanup of one of the older sections of Santa Cruz, Bolivia. He found 200 of the 280 homes lacked a potable water supply, and the 1,745 residents had only 11 latrines, all substandard. Garbage was thrown into the streets for animals to devour or the rains to wash away.

The sanitary inspector organized a health and sanitation committee among the residents. The committee surveyed the area and, with help from the local health center, started community meetings with discussions, films, and talks.

Enthusiasm and community pride led to the construction of a public well and 221 latrines. Streets were cleaned and graded, and nearly all the families began burning or burying their garbage. The residents themselves did all the work and provided the materials, except for a handpump and its accessories.

At the public dedication of the well, citizens from nearby sections of the city were so impressed that they asked the health center to help them make similar improvements in their own neighborhoods.

—HARALD S. FREDERIKSEN, M.D., *chief, Health and Sanitation Division, U. S. Operations Mission, Bolivia.*

the disease was fifth among registered communicable diseases in 1937. He also pointed out that there were considerable numbers of recently infected as well as untreated persons and some cases with high indexes of positive serology.

The great majority of cases of venereal disease in Mexico are latent, he asserted. For that reason, serologic test laboratories and equipment have been augmented. Measures have also been taken to standardize and coordinate serologic test reports from all sources, and to make VDRL antigens available to all national laboratories. Training, briefing, and specialized instruction for the venereal disease campaign have been emphasized for personnel of medical agencies and institutions, private physicians, and community leaders, on whom the Ministry depends heavily in this drive.

As a public education device supplementing posters, pamphlets, and lectures, a film was produced in color and exhibited in leading cities. Campos Salas remarked on the growing facility in organizing public meetings for campaign purposes.

Venereal Disease Control Progress Report

In presenting the United States program in venereal disease control, Dr. William J. Brown, chief of the Venereal Disease Branch, Public Health Service, reported that in the United States the rate for syphilis has dropped from 447 to 81 per 100,000 population since 1943, the year penicillin came into use.

Although institutional care of the syphilitic insane still costs an estimated \$46 million a year, over a 10-year period first admissions of such patients have dropped from 7,000 to 2,150 annually.

In the past 6 years, an increasing number of States have been reporting more early syphilis. Reported cases of primary and secondary syphilis are 11 percent higher this year than last. Gonorrhea rates, at the same time, have shown little change. An alarming percentage of venereal disease is being found in

young people. Many infectious disease cases treated by private physicians are not being interviewed for sex contacts.

Brown reviewed the following current developments:

- Rapid plasma reagin test is revolutionizing the testing of migrant laborers. Immediate diagnosis and treatment prevents spread of infection and returns the once infected person to work without delay.

- Reiter protein complement fixation test, a specific treponemal test for diagnosticians, promises important savings in costs.

- Fluorescent antibody tests for both syphilis and gonorrhea may eventually provide rapid and inexpensive methods of detection.

- A casefinding procedure called "cluster testing" covering friends and associates of infected persons as well as sexual contacts may double the epidemiological yield.

- The training of 1,500 public health workers in 1937 by the Public Health Service is promoting more effective interviewing techniques.

- Epidemiological services to patients of private physicians have been demonstrated as a practical control measure and are being extended to many areas.

- A uniform report form for reporting venereal disease contacts and suspects in the United States has been developed, and many State health departments are considering its adoption in the interest of standardization of interstate routing of the forms.

New Mexico Aims To Stop Primary VD Infection

During the first quarter of 1938, accelerated casefinding in New Mexico was a factor in a 193 percent rise in reported syphilis and a 166 percent increase in reported gonorrhea, over the same period in 1937, according to members of the New Mexico Department of Public Health: Dr. Arthur D'Jang, director of the division of chronic disease, Dawson T. Kilcrease, health program representative in the division of venereal disease, Marion Mc-

Breen, associate bacteriologist, public health laboratory, and Dr. Stanley J. Leland, State director.

The effectiveness of the State's program, they said, is indicated by the rate of first admissions to State mental hospitals for all psychoses due to syphilis in 1935: it was 0.7 per 100,000 population, lower than the mean rate for continental United States.

Program Highlights

A confidential survey of physicians in New Mexico conducted in October 1937 revealed 640 more cases of venereal disease than were obtained from morbidity reports in the first 6 months of 1937. To stimulate reporting, the department devised a private physician's information packet with suggested treatment schedules, health education materials, evaluation of serologic reactions, and an interpretation of the new treponemal tests. Also offered was medicine for the physician's indigent patients.

Besides following up about 85 percent of the reported reactive serologic tests for syphilis and investigating 97.6 percent of reactors among braceros, the department trained several Navajo Indians and employed them as venereal disease investigators. Although Indians represent 5 percent of the people in the State, they contributed about 50 percent of the morbidity from venereal disease in 1937. In a survey including inmates of 4 prisons in the Navajo training experimental health district, a total of 2,129 serologic tests were made from June 1937 through February 1938. Navajos accounted for 96 percent of those tested. In the Navajo group, 10.1 percent were reactors, compared with 7.1 for the others.

Serologic Test Laws

Premarital serologic tests are required by a law passed in May 1937 in New Mexico, they said. Another law approved in 1949 requires all pregnant women to be tested for syphilis before delivery.

A serologic test is incorporated in a multiphasic survey among school and college students and teachers

choma, diarrhea, dysentery, the communicable diseases of childhood, and impetigo are the current challenges among these people, he said, suggesting that exploratory conversations between officials of the Division of Indian Health of the U. S. Public Health Service and their Mexican colleagues might produce improved coordination in work for such tribes.

Another activity he touched on was the study carried out jointly by the Communicable Disease Center, Public Health Service, the Mexican Ministry of Health, PASB, and border States on insectivorous bats, which on occasion infect man. A station has been set up by the Service in Las Cruces, N. Mex., to unravel the puzzling epidemiology of rabies among these bats, of which the Mexican freetailed bat is the predominant species.

He also mentioned Communicable Disease Center studies and demonstrations in enteric disease vector control, coccidioidomycosis, and encephalitis, as well as training programs.

Price concluded with remarks on the international ramifications of research at the National Institutes of Health of the Public Health Service. There are several Mexican participants in the current program, but he wondered whether those most concerned with border health were fully utilizing grant resources. He affirmed the great interest of the Public Health Service in the border area, where, he feels, the philosophy of international health is translated into action.

Urges More Casefinding For Congenital Syphilis

Discussing the methods of finding cases of syphilis among pregnant women, Dr. Edith P. Sappington, regional medical director for the Children's Bureau, San Francisco, Calif., declared that all too many women receive no prenatal care until the second or third trimester. Moreover, though most hospitals give serologic tests for syphilis on all admissions, the cases found are either lost or fol-

lowed with difficulty because low-income mothers stay in the hospital so briefly.

She advocated wider application of a second test for pregnant women during the third trimester, at least where there is a high prevalence of syphilis, referring to the suggestion that certain patients, such as those in lower socioeconomic groups, unwed mothers, and welfare hospital patients, should have two or more tests during pregnancy.

To bolster casefinding during the infant and preschool period, Sappington suggested that hospital records of mothers of children entering child health conferences be checked for evidence of serologic tests for syphilis. Mothers delivered by midwives might be routinely tested at the conferences. Though laborious, these methods she feels are justified, since congenital syphilis has not decreased in the past 2 years.

Maternal and child health programs also could incorporate such testing into school physical examinations, she added.

Sappington also pointed to the desirability of integrated health care for all members of a family. If all went to a single physician or clinic, congenital syphilis would not easily escape detection.

Reviews Clinical Aspects Of Congenital Syphilis

During the past 12 years, the cases of congenital syphilis reported annually in the United States have fallen only by 50 percent, compared with a drop of more than 90 percent in acquired early syphilis. This was pointed out by Dr. Willie G. Simpson, assistant chief, Venereal Disease Branch, Communicable Disease Center, Public Health Service, Atlanta, Ga., who feels that the current incidence of congenital syphilis is excessive in the light of the availability of penicillin.

Simpson described the clinical aspects of congenital syphilis in considerable detail. In his comments, he mentioned:

- In the early stages of congenital syphilis, demonstrable lesions may

be absent, but they usually appear in the first 2 to 3 months of life if not already present at birth. Bone changes occur within the first 6 weeks, compared with scurvy changes after 6 months, and rachitic changes between the 8th and 18th months.

- In diagnosing asymptomatic congenital syphilis in the newborn only an increasing titer and positive serology at 3 months of age are significant. Before then, reagin found in serology tests may be from the mother. Conversely, infants with negative serology but diseased mothers should be followed up for at least 3 months. Syphilis may be suspected at birth if the serology report shows a higher titer than for the mother at the time.

- Since adults with the congenital disease will be seropositive long after treatment, retreatment should be based on definite signs of relapse.

- A higher rate of seronegativity is attained in those treated during the first year of life, than in those treated later, regardless of the amount of penicillin given above the minimum adequate dosage. The patterns of response resemble those for treatment of acquired early syphilis and during latency after 2 years of infection respectively.

- Treponemal antigen tests are valuable in cases of clinically suspected congenital syphilis with reactive or nonreactive reagin tests.

VD Control Intensified In Bracero Home Areas

In the home states of most of the braceros, the Mexican Ministry of Health and Welfare has broadened efforts to gather venereal disease data, to test prospective agricultural migrant workers serologically, and to treat those infected.

Other aspects of the Mexican Government's drive against venereal disease described by Dr. Antonio Campos Salas, chief of the Ministry's campaign against venereal diseases, have also been expanded. In spite of a general downward trend in syphilis mortality and morbidity in Mexico since 1948, he said,

and training of nursing home operators and aides.

In conclusion, he reported that many States have initiated new services for the aged and chronically ill through appropriations voted by Congress for that purpose in 1957.

About 30 percent of the population of the United States is 45 years of age or over, he noted, and 40 percent of the chronically ill are 65 years of age or more.

Isoniazid Reduces TB In Children

A year's work by the Public Health Service investigating the effect of isoniazid on 2,700 children with primary tuberculosis in the United States, Puerto Rico, Mexico, and Canada has presented physicians with a new method for control of this disease.

Dr. Edward T. Blomquist, chief of the Tuberculosis Program, Public Health Service, reported that among the children who have been taking isoniazid, the major complications of childhood tuberculosis have been practically eliminated. He advocated small daily doses of isoniazid for a year for infants who are tuberculin positive and those between 1 and 4 years old with X-ray evidence of the disease.

Another branch of the study will measure the prophylactic potential of isoniazid among older persons who, although not now exposed to tuberculosis, were infected in childhood. Evidence is accumulating, Blomquist said, that most new cases of clinical tuberculosis appear to occur among persons with subclinical infection which becomes active during stress or lowered resistance.

Care and supervision of nonhospitalized tuberculous patients must be expanded and strengthened by health departments, he feels, to meet the shift in emphasis from institutional to home care for tuberculosis patients. Health agencies, with their responsibility to protect the public from the disease, can do so by keeping active cases under care until noninfectious, with broadened clinical and nursing services, and by

keeping information on nonhospitalized patients current. Their program, he concluded, must include diagnostic, treatment, and social services, as well as public health supervision.

Home TB Care Boon To Low-Budget Lands

For countries without ample means, ambulatory home care of tuberculosis patients, instead of hospital treatment, has opened up new horizons, stated Dr. Donato G. Alarcón, chief of the campaign against tuberculosis, Ministry of Health and Welfare, Mexico.

Together with modern medication, this therapy allows such countries to undertake broad campaigns against tuberculosis without dependence upon related social and economic factors. Mexico's mortality rate from tuberculosis, he said, has dropped from 69 per 100,000 population in 1930 to 38.

Describing the antituberculosis campaign in Acapulco (population, 30,000) as a low-cost pilot project, Alarcón reviewed results of 2 years' work there: 1,025 cases of active tuberculosis were discovered; 57.3 percent of school children 6 to 12 years old were found to have positive tuberculin reactions; and during the first year of the campaign, negative concentration smears were obtained for 70 percent of tuberculosis cases.

In the opinion of Alarcón and Dr. Salvador Roquet Perez, secretary of the Ministry's campaign against tuberculosis, consistent recovery of tuberculosis patients depends more on their economic status, education, and attitude toward the disease than on hospital facilities. They attributed to social and economic factors the fact that in a previous study 65 percent of the ambulatory patients who received thoracoplasty and pneumothorax were classified as arrested and later cured. These results compared favorably with results for long-hospitalized patients elsewhere.

Although home ambulatory treatment for tuberculosis has been en-

dorsed, there is still a hospital shortage in Mexico. They concluded with details of Mexico's plans for expansion of tuberculosis hospital space in Mexico City, San Fernando, Monterrey, Tampico, and Xaltianguis.

Bovine TB Hazard Still Looms

Although tuberculosis in cattle has been reduced to 0.156 percent in the United States, dangerous foci of the infection remain. Dr. Donald Miller, veterinarian in charge, Animal Disease Eradication Division, Agricultural Research Service, U. S. Department of Agriculture, Phoenix, Ariz., stated that, during fiscal year 1957, 28.9 percent of cattle reacting to the tuberculin test showed gross lesions.

Eradication in Border States

In discussing eradication of the disease on the border, he described as essential the vigorous tracing by epidemiological means of herds of origin when infection is found postmortem at regular kill in a packing house. For example, the recent tracing of the source of such a lesion in Texas ended in finding 40 reactors in a herd of 139.

During fiscal year 1957, Texas had 611 reactors of which 22.8 percent showed gross lesions. In New Mexico, with a consistently low level of infection, reaccreditation will be tried for 6 years instead of the usual 3. Miller explained that reaccreditation may be given when infection is under one-half of 1 percent of area cattle tested. Arizona also has low incidence, due, in his opinion, to such measures as testing all dairy and purebred cattle and 20 percent of all pastured beef cattle every 3 years.

For California, faced with non-specific reactions in certain herds and areas, Federal and State officials have developed trial testing procedures using intradermic tests with mammalian and avian tuberculins and johnin; cervical, caudal, and ophthalmic tests; and careful epidemiological studies and complete postmortems.

and among industrial workers. During a migrant survey in 1957, a mobile unit with laboratory facilities was used, and another unit added in 1958 provided medical facilities for sparse population areas.

Three more programs were begun during 1957-58: the rapid plasma reagin test, the unheated serum reagin test, and the mass Frel skin test.

In reviewing phases of the control program, D'Jang and associates drew attention to the emphasis on primary prevention of venereal diseases, through health and sex education in schools and clubs; prophylaxis instruction in defense installations; provision of recreational facilities; and suppression of prostitution. They underlined the value of facilities for early diagnosis and treatment, believing that the cooperation of the public rests not only on mass education about symptoms and modes of spread but on the availability of diagnosis and treatment facilities without respect to the infected patient's economic status.

Los Angeles District Surveyed for MCH Needs

Two maternal and child health surveys carried out in the Northeast Health District of Los Angeles, Calif., during 1956 were reported by Dr. Stella B. Soroker, district health officer, and Thelma Herold, health educator, Los Angeles City Health Department.

Health problems in Boyle and Lincoln Heights, the survey sites, resemble those on the border, they explained. These sections have more residents of Mexican origin or descent than any border city. The northeastern area, moreover, is a port of entry for Mexican arrivals.

Citing statistics depicting needs of these areas, especially with respect to infant mortality, they said that, because of extraordinary mobility of the population, newcomers are often unaware of local health resources. During 1955 one-third of the prenatal cases and one-half of the newborn received some health department supervision. The MCH

surveys sought to determine the gaps in health care for those unreached and reasons for the gaps.

Boyle Heights Survey

With volunteers from local societies, a hospital, and a junior college, the department began interviewing 500 to 600 Boyle Heights families with babies born during February through April 1955.

The interviewers found that of 232 families reached out of 662 families with children born a year before, 66 percent knew of MCH facilities and 87 percent of the mothers had received prenatal care. No protection against diphtheria, whooping cough, and tetanus was given to 22 percent of the 1-year-old population; 35 percent were not vaccinated against smallpox; and 9 percent had no health supervision. Sixty-eight percent of the families interviewed knew of services and locations of well-baby clinics.

Among reasons for not seeking protection from childhood diseases were lack of information as to the need or availability of services, indifference, and parental fear.

It was also ascertained that by 1 year of age, respiratory diseases accounted for 40 percent of conditions needing medical care, and accidents, 11 percent.

The health department recommended intensifying efforts to reach newcomers through publicity, nursing visits, and civic and religious organizations, stressing accident prevention among younger age groups, and conducting Red Cross classes for expectant parents.

Lincoln Heights Survey

In Lincoln Heights, they said, a newly formed committee of community leaders, PTA delegates, and professional persons, aided by volunteer residents, interviewed 275 families with children between 2 and 5 years old. Sampling required visiting 15 out of 100 households.

Applying the findings to the approximate total of 3,000 preschool children in the area, they estimated that 82 percent are protected against diphtheria, whooping cough, and tetanus, 71 percent against small-

pox, and 48 percent against poliomyelitis. Sixty-nine percent of the families knew about the well-baby clinics, and the reasons for not seeking protective services matched those in Boyle Heights.

Outlines Health Agency Role In Chronic Disease Battle

Advances to be made in long-term patient care, in the opinion of Dr. Wilfred D. David, chief of Program Services, Chronic Disease Program, Public Health Service, will be closely bound up with progress in public health, medical care, and in developing adequate hospital facilities.

Prevention of certain diseases, he said, is the proper direction for many programs related to chronic illness and health needs of the aged. He remarked that preventive action is now possible for more than 50 chronic diseases. Preventive programs can stop or slow a disease's progress by early detection and early therapy, and can soften the economic and social effects of the disease for patient, family, and community.

He emphasized that these programs must be started by community initiative, be part of the total community health drive, and be spurred by health agency aid.

Types of activities of the Public Health Service in support of State and local programs named were training, consultation, dissemination of information, demonstrations, and technical assistance as well as regional seminars.

David suggested the following fields for community action: diabetes casefinding with referral for diagnosis, the techniques of which have been refined; diabetes patient instruction on diet, self-administration of insulin, and personal hygiene; glaucoma screening through tonometry performed by an ophthalmologist, with referral arrangements; restorative services for patients with cerebral vascular accidents; and improvement of nursing home facilities through consultation

He estimates that, under field conditions, a 6-inch layer of compacted earth cover should prevent fly emergence.

Fly emergency traps can be used to determine the required thickness of cover and the amount of compactive effort necessary for local conditions. When the covering soil is not compacted, he said, flies can be reduced by quickly covering the refuse with a thin cover of soil to prevent more fly oviposition.

Reporting Aids Suggested In Diarrhea Seminar

Morbidity data on diarrheal disease, not officially reportable, can be gleaned from sampling surveys or from the evaluation of requests for services received by public health nurses, according to a recommendation emerging from the seminar on diarrheal diseases.

Participants stressed that in sections with a deficiency of health services, family cooperation is particularly important, even in reporting deaths. Therefore, health agencies were urged to convince families that their information will produce benefits in the form of health services. Since mortality reporting depends on competent diagnosis, it was agreed that improvement must develop locally.

Among needs mentioned to circulate and apply laboratory knowledge and resources were simplified, standardized laboratory methods and kits for shipping specimens.

Piping water into the home, as a means of reducing the sources of diarrheal disease, is usually the responsibility of agencies other than the health department. Such achievement, it was agreed, would result only from combined effort of all agencies, with encouragement from community organizations and active participation by individuals.

Though the importance of flies as vectors is recognized, fly control measures, according to the discussions, are less effective than piping water into individual homes. During peak periods of infection, suppression of flies should be encour-

aged, it was agreed, but with the realization that "flies are resistant to everything but sanitation."

Educational efforts were urged to explain the advantages of putting animal quarters in a separate building and to emphasize the ease with which food, particularly meat and fowl, can be infected during slaughtering and processing.

For treating dehydration, the principal cause of death in diarrhea victims, the prevailing opinion was that the local health agency should train suitable persons in simple methods. The chosen personnel, who must be acceptable to the families, should evaluate the adequacy of treatment facilities in the home and inform the mother of procedures to be used. The success of treatment hinges on how well the mother has been taught to recognize dehydration and on how promptly the treatment starts.

Turning to the financing and coordination of efforts by border communities, the participants advised cooperation by adjacent communities in defining joint problems, sharing observations and methods, and standardizing procedures. Communities can then either persuade higher-level agencies to take action, or they can rely on local resources. In many communities, a school teacher has been a key person in promoting the program, not only among pupils but also among families and local authorities.

Diarrhea Incidence Highest in Mexican Uplands

Mexico's highlands, in spite of their temperate or cold climate, have more diarrhea than other sectors when similar adverse environmental or social factors are present. This was one of the findings from field studies mentioned by Dr. Manuel E. Pesqueira, Deputy Minister of Health and Welfare in Mexico. Less diarrhea mortality occurs in tropical regions with abundant water and food. Attacks in these regions, though less frequent, may be more violent.

Although mortality from diarrhea in Mexico is decreasing, he empha-

sized that the rate of 235.2 per 100,000 persons for 1952-56 is still higher than for all other communicable diseases registered during that time. To develop more exact statistics on the disease, the Ministry is contemplating setting up one or more areas of careful registry in each state.

In almost all of the Mexican states, the government has projects for water supply systems, building public baths and laundries, improving homes, installing latrines, and destroying insect-breeding grounds. In all such communities, he said, health education and maternal and child health are stressed. Mothers are taught correct baby care and feeding and are trained in home sanitation, aspects of home economics, and home care of sick children, including prevention of dehydration when diarrhea strikes.

Mexican VD Health Workers Trained in Mobile Units

In a detailed description of how a mobile unit contributes to the Mexican venereal disease campaign, Dr. Alfonso Verduzco Peñafiel, epidemiologist with the antiveneral campaign of the Mexican Ministry of Health and Welfare, related that the unit was first acquired by the Ministry in 1956 both to train personnel and to standardize control techniques throughout the country.

In addition to a laboratory for technician training and for evaluating local laboratory facilities for syphilis serodiagnosis, the unit has audiovisual units for health education and material for serologic tests, treatment, and prophylaxis.

A teacher of health sciences specializing in the program techniques and a trained contact interviewer comprise the unit's personnel, he said. After presenting the program's objectives, methods, organization, and personnel to local officials, the team begins fieldwork with public health nurses seeking such training. Among the groups tested are prostitutes, prisoners, and soldiers. The unit supplies the local laboratory with basic equipment and mate-

National Figures

Nationally, fiscal year 1957 was the third straight year with a slight infection rise, Miller said. Among 8,976,469 tuberculin-tested cattle infection appeared in 13,974. Of 14,054 reactors slaughtered, 319 carcasses, or 2.3 percent, were condemned.

Miller alluded to the lack of veterinary personnel in eradication programs. "This is no time for the veterinarians, health officials, and cattle growers to leave the field because we have a comfortable lead" he said. According to Miller, if we slacken in eradicating bovine tuberculosis, the progress of 10 years will be erased.

A Look Backward

Roughly 10 percent of tuberculosis in humans is of bovine origin, according to a study cited by Dr. Robert D. Courter, assistant chief, Veterinary Public Health Section, Communicable Disease Center, Public Health Service. But in areas with heavily infected herds the percentage is as high as 50.

About 378 million tuberculin tests have been made in cattle since the program's inception 40 years ago. Then, the program's harm to agriculture was prophesied, and the communicability of bovine tuberculosis to humans doubted. In fact, Koch, discoverer of the tubercle bacillus, was unconvinced of the need for protection against consumption of food from infected cattle.

Since antiquity, Courter related, man's attitude toward the disease has fluctuated between abhorrence and indifference. Eighteenth century laws levied drastic penalties, including exile, on those who sold meat of tuberculous cattle. Tuberculosis was then believed identical with syphilis, but when it was understood that the two diseases were not the same, aversions to such meat faded.

In the nineteenth century, he continued, when the infectious nature of tuberculosis was recognized, German veterinarians advised farmers to dispose of tuberculous animals and to cook milk before feeding

young animals, presaging pasteurization decades later.

The effects of pasteurization and the reduction in bovine tuberculosis in the United States elude easy evaluation, in Courter's opinion. A commonly used index of progress in eradicating the disease is the fall in deaths from extrapulmonary forms of tuberculosis in humans. Since the drop in mortality from the pulmonary form has paralleled that from the extrapulmonary, he feels that such an index fails to consider effects of improved social and economic conditions and control measures among humans.

Four Polio Vaccine Doses Recommended in Mexico

Based on field observations, modification of the standard dosage plan for administering poliomyelitis vaccine was suggested for use in Mexico by Dr. Carlos Calderón, Dr. Carlos Ortiz Mariotte, Dr. Adán Ornelas Hernandez, and Dr. Louis Gutierrez Villegas of the Mexican Ministry of Health and Welfare.

In a program administering Salk-type vaccine, which was carried out by the Ministry from October 1956 to December 1957 on about 221,000 children aged 6 months to 3 years, more than half of the observed poliomyelitis cases among those injected had onset from 1 to 3 months after the second dose. This led to the proposal that a dose be added from 1 to 3 months after the second, and that the reactivation dose be given 7 months later.

They found that the attack rate for those not immunized was at least 3 times higher than for children vaccinated; and among those immunized, the attack rate was higher, the fewer doses received.

Another observation was that among 150 blood specimens taken from children under 5 years old, only 10 percent of those from children having 3 doses were without antibodies. One-third from those not immunized showed antibodies, one-fourth having titrations of 1:64 or more. These results sug-

gest that the vaccine stimulates antibody formation.

The vaccine, they explained, is made in Mexico using 2 parts, instead of 1, of type 1 strain, isolated in practically all cases of acute poliomyelitis in Mexico. Instead of Salk strains, those attenuated by Sabin are used. Studies carried out on about 5,000 children in 3 districts of high prevalence in 1956 and 1957 had already indicated the children's tolerance to the vaccine as well as its effectiveness. Further studies are recommended to test vaccine made in Mexico from strains used by Salk, they said.

Study Burial of Refuse As Curb on Flies

Whether prompt burial effectively inhibits fly emergence from refuse, which during collection in warm weather already abounds in fly eggs and larvae, was the subject of studies carried out by the bureau of vector control, California State Department of Public Health.

Ralph J. Black, senior vector control specialist with the department, reported that laboratory tests during the summer of 1955 showed that fly emergence was prevented if the soil was compacted at or near the optimum moisture content, in layers varying from 1½ inches to 2¼ inches deep. Houseflies emerged through 60 inches of uncompacted earth.

Conclusions from these and subsequent field tests underlined as essential factors soil that can be compacted, adequate range of soil moisture, suitable equipment for compacting, and adequate enough thickness of cover. Generally, sand, nearly pure clay, silt, and crushed rock do not compact well enough to prevent fly emergence, he said. Field moisture content of soil is adequate if a solid clod can be formed by hand squeezing. A bulldozer was suitable for soil compaction with repeated tracking over the cover material. When applying the earth cover, tractor operators must compact side slopes as well as the top cover to prevent fly emergence.

Environmental Factors and Enteric Disease

COAL MINING communities with diversely housed population groups in eastern Kentucky were the locales of a field study to provide basic information for development of specific control measures against diarrheal diseases by determining seasonal and annual prevalence of diarrheal diseases among human populations of areas differing from one another in one or more environmental characteristics, identifying contributory factors in diarrheal disease in the different communities, and evaluating levels of sanitation in households and in the communities studied.

The study was conducted by the Communicable Disease Center of the Public Health Service with the cooperation of the Kentucky State Department of Health. During the period of study, observers determined diarrheal disease morbidity rates, *Shigella* infections in preschool children, and percentage of population infected with *Ascaris*, in 11 communities. Marked seasonal trends in reported morbidity were recorded, the highest incidence occurring during August and September. The ratio of "summer" diarrhea to "winter" diarrhea for the years 1955 and 1956 was approximately 2 to 1. Diarrheal disease prevalence increased earlier in the spring and persisted at a high level longer in the fall in areas where sanitation was least observed. Severe diarrhea was more frequently reported from the less sanitary areas.

Shigella prevalence rates obtained by rectal swabbing of preschool children ranged between 0.7 percent and 10.2 percent in individual study areas. The highest prevalence for all study populations combined occurred in the 4-year age group; in the least sanitary areas children were found to be infected at an earlier age, and the highest prevalence was in the 2-year age group. Variations in *Shigella* prevalence did not correspond to seasonal variations in reported diarrheal morbidity. Shigellosis was responsible for the majority of acute diarrheal

disease experiences observed in areas lacking sanitation, but was not a primary cause in the best sanitated area. *Salmonella* and the enteropathogenic *Escherichia coli* evidently did not contribute substantially to diarrheal disease morbidity reported in the study areas.

One of every four of the 2,798 individuals of all ages examined had stools positive for *Ascaris lumbricoides*. In the particular region

Schliessmann, D. J., Atchley, F. O., Wilcomb, M. J., Jr., and Welch, S. F.: Relation of environmental factors to the occurrence of enteric diseases in areas of eastern Kentucky. Public Health Monograph No. 54 (PHSPub. No. 591). 35 pages; illustrated. U. S. Government Printing Office, Washington, D. C., 1958. Price 30 cents

rial for diagnosis and trains the health personnel in campaign methods.

For treatment of prostitutes, the team recommended weekly dosages of 300,000 units of penicillin procaine with aluminum monostearate or 600,000 units of penicillin benzathine every 2 weeks.

Goals for Community Action Against Alcoholism

What should the community do about alcoholism? What would you like to see in your community 20 years from now? Here are some of the things that I think can be attained in the next 20 years, if we make use of the things we now know:

- * Citizens who recognize that some people cannot drink in moderation and that those people cannot be blamed for the conditions that made them alcoholic. In other words, an informed public.

- * Police officers who have some knowledge of alcoholism and who consider helping alcoholics part of their job as well as protecting the rights of others.

- * Courts and laws which recognize that help for the alcoholic is far more effective than is punishment.

- * Physicians who are ready, willing, and able to treat the acute phases of alcoholism and to use their skills to join with the community team that offers help for the chronic aspects of the illness.

- * General hospitals whose beds are as available to acutely intoxicated patients as they are to diabetics, and nursing staffs who recognize that there is more to alcoholism than intoxication.

- * Clergymen who are aware of the spiritual problems faced by alcoholics and their families and are ready to use their counseling skills to help rather than condemn.

- * Social agencies who offer their help to families where alcoholism has intensified normal social problems and who use their skills to help the individual alcoholic.

- * Health departments that feel as much responsibility toward alcoholism as they do any other public health problem.

- * Employers who recognize the early symptoms of alcoholism in employees, and who protect the investment they have made in these people, by getting help for them before they jeopardize their jobs.

—RALPH W. DANIEL, *executive director, Michigan State Board of Alcoholism*
(from a speech given at the Midwest Institute on Alcohol Studies, June 23-27, 1958).

Calculating Home Range and Density of Small Mammals

TWO interrelated aspects of animal population ecology are considered in this monograph. First, a mathematical formulation describes how individual animals use the space radiating from their homes. This space is designated as home range. Second, from this formulation, mathematical formulations are developed for estimating density by the use of capture data.

The probability of recording an animal per unit of area about its home or center of activity is adequately described by the bivariate normal distribution function. The farther a locality is from the center of an animal's activity, the less likelihood there is that the animal will be observed there.

In estimating density, it is customary to use some sampling device which has a discrete location in space. Obviously, some animals will live close to this device and others farther away. Where the use of space is describable by the bivariate normal distribution function, those animals living close to the sampling device will have a higher probability of being sampled than will those living farther away. With this insight into home range, it is possible to arrive at reliable estimates of density from a sequence of samples representing portions of the population removed.

Although the data in this monograph concern certain mice and other small mammals, application of the formulations presented can lead to much more precise information than is now available on the role of mammals in the epidemiology of diseases for which they serve as reservoir hosts.

The formulations concerning home range are of particular relevance in the study of animal behavior and population dynamics. They pro-

vide a basis for understanding the phenomenon of territoriality as well as a basis for measuring contact rate among members of an animal population.

Public Health

MONOGRAPH

No. 55

The accompanying summary covers the principal findings presented in Public Health Monograph No. 55, published concurrently with this issue of Public Health Reports. The senior author is with the National Institute of Mental Health, National Institutes of Health, Public Health Service, Bethesda, Md.; the junior author is with the Eastern Pennsylvania Psychiatric Institute, Philadelphia, Pa.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Health Service. Copies will be found also in the libraries of professional schools and of the major universities and in selected public libraries.

Calhoun, John B., and Casby, James U.:
Calculation of home range and density of
small mammals. Public Health Mono-
graph No. 55 (PHSPub. No. 592). 24 pages.
U. S. Government Printing Office, Washing-
ton, D. C., 1958. Price 25 cents.

studied, *Ascaris* infection rates were found to be at least as suitable an index of enteric disease prevalence and of environmental sanitation as *Shigella* infection rates. In the group 2 to 12 years of age, *Ascaris* infection rates ranged from 12 to 70 percent among the study populations. Rates of *Trichuris trichiura* approximated those of roundworm, although the whipworm infections, as judged by egg counts, were almost invariably much lighter. *Strongyloides stercoralis* infections were occasionally recorded and hookworm infections were rare. Prevalence of *Entamoeba histolytica* did not exceed 3.3 percent; *Giardia lamblia* and the remaining intestinal protozoa recorded prevailed at rates corresponding to ranges reported elsewhere in the United States.

Comparatively low levels of fly abundance, including houseflies, were evident in the areas under study. While it may logically be assumed that flies as mechanical vectors contributed to the reported morbidity rates and *Shigella* prevalence, the level of fly-transmitted diarrhea during the period of study was too low to be measured by the indexes available. Similar conclusions were reached with respect to studies of the role of water in enteric disease transmission. With the exception of one public supply and a very few properly constructed drilled wells, water sources in use by the study populations were subject to possible fecal contamination and may have been responsible for some cases of diarrheal disease. There were, however, no instances in which water quality could be implicated in localized outbreaks or correlated with seasonal differences in morbidity rates or *Shigella* prevalence.

Lowest rates of reported diarrheal disease, *Shigella*-positive cultures, and *Ascaris*-positive stools were recorded among study families

served by complete community sanitary facilities; markedly higher rates of all three enteric disease indexes were experienced by households served by some but not all public sanitary services; and the highest levels of the three indexes were reported from populations living where community sanitary facilities were entirely lacking. Individuals living in homes provided with inside piped water and privy excreta disposal experienced approximately twice the diarrhea, twice the *Shigella* prevalence, and four times the *Ascaris* prevalence experienced by individuals using inside piped water and flush toilets. Where water was not piped inside the house, persons having access to water on the premises experienced approximately a third less diarrhea than individuals obtaining water away from the premises. Where the water source was outside the dwelling unit, *Shigella* prevalence and *Ascaris* infection rates were comparable regardless of the location of the water source in relation to the premises.

Of several socioeconomic factors analyzed for possible influence upon enteric disease rates, only crowding, family size, and education of the mother appeared to affect rates appreciably. High person-per-room ratios, large families, and low educational levels of the mother all generally accompanied high *Ascaris* and *Shigella* prevalence. The combined effect of these factors on observed prevalence of diarrheal disease was not, however, as great as the lack of adequate sanitary facilities.

Results of these studies strongly support the premise that incidence of acute infectious diarrheal disease may be significantly reduced through selective modification of specific environmental factors within communities without regard to etiological or sociological differences.

publications

Selected Materials on Staphylococcal Disease. *PHS Publication No. 627; 1958; 237 pages; \$1.25.*

Selected reprints of articles from medical journals, information on teaching aids, list of additional readings, locations of phage typing centers, and recommendations of several professional associations are provided for instructors, physicians, nurses, and laboratory personnel.

This book may be used either as a refresher document or for orientation.

Accidental Injury Statistics. *PHS Publication (unnumbered); 1958; 61 pages.*

Salient facts about injuries and deaths from accidents in the United States are presented in a series of charts and tables prepared for health departments and agencies concerned with accident prevention.

The report is divided into sections dealing specifically with incidence of nonfatal injuries, leading causes of death, trends in accidental deaths over a 50-year period, types of accidents, relationship of accidents to marital status, and place of residence.

National Health Survey data collected in sample household interviews, figures provided by the National Office of Vital Statistics, and information contained in several selected studies of accidental injuries are included.

Statistical Summary of Sewage Works in the United States. *PHS Publication No. 609; 1958; by John R. Thoman and Kenneth H. Jenkins; 40 pages; 20 cents.*

Based on the 1957 Inventory of Municipal and Industrial Wastes Facilities, this report summarizes and analyzes data on community sewage disposal works in the United States.

Comprehensive data for all phases of sewage collection and treatment are tabulated according to States, population size groups, and major

drainage basins. Detailed analytical tables are given and comparisons are made with appropriate prior information.

This report provides the background information for use in conjunction with PHS Publication No. 619, *Municipal Sewage Treatment Needs.*

Indians on Federal Reservations in the United States. A digest. Billings Area. *PHS Publication No. 615, part 2; 1958; 17 pages.*

Brief information about each of the eight Federal Indian Reservations in Montana and Wyoming is contained in this digest.

The population groups, their homes, education, and income, and their health status and services are discussed. Included also is a description of the location, ownership, and topography of the reservation land.

Physicians' Handbook on Death and Birth Registration. *PHS Publication No. 593; 1958; 11th edition; 38 pages; 20 cents.*

A minor revision of a publication issued in 1949, this booklet contains facts which the practicing or prospective physician should know concerning birth, death, and fetal death registration requirements and procedures. Selected references are presented and vital statistics offices listed alphabetically by State or Territory.

Using Your Community's Health Resources. *Department of Agriculture Rural Research Leaflet No. 5; 1958.*

Steps aimed at improving use of available health services to meet rural community health problems are listed in this leaflet, prepared jointly by the Department of Agriculture and the Public Health Service. Suggestions include a study of the local situation, closer cooperation between local private and public groups, assessment of present health

facilities, and a communitywide campaign to promote better health.

Written in nontechnical language, the leaflet should be useful to public administrators, civic leaders, county agents, farm organizations, and clubs. Copies may be obtained from the Publications Office, Agricultural Marketing Service, U. S. Department of Agriculture, Washington 25, D. C.

Good Water Makes Good Neighbors. *PHS Publication No. 626; 1958; 7 pages.*

This pamphlet was designed to alert women's clubs to the urgency of the Nation's water pollution problem. It provides a brief outline of the situation, suggestions for action by women's clubs, and discussion topics.

Published Scientific Papers of the National Institutes of Health, 1957. *PHS Publication No. 618 (Public Health Bibliography Series No. 23); 114 pages.*

Papers presenting original work of scientists at the National Institutes of Health, Public Health Service, published during 1957 are listed in this bibliography. Titles are arranged by institute, division, and laboratory to which the senior author was attached when the work was done.

An author index shows the extent of multidisciplinary approach to research problems and reflects the contribution of all authors as well as each unit.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D. C.

The Public Health Service does not supply publications other than its own.

Signs

and

of Trends in Public Health

"How To Be a Nursing Aide in a Nursing Home," a manual produced by the Public Health Service and the American Nursing Home Association, will be used by the Army as a text for inservice education in hospitals.

« »

Improvement in sanitation of food stands operated by the blind resulted from recent Public Health Service inspections in Federal buildings in Denver, Colo.

Responding to a specific request by the General Services Administration, the inspectors found that sandwiches with perishable fillings were not being properly refrigerated. Mechanically refrigerated display cases were promptly procured by the Colorado Division of Rehabilitation for the Blind. By this action, blind operators have increased the number and variety of perishable products offered for sale, with a consequent improvement in sales.

« »

A survey by the North Carolina Industrial Commission unearthed the fact that, over a 24-month period, 75 percent of the accidents happened to workers who had not eaten breakfast. The largest number of injuries occurred at 10 a. m.

« »

Portable kerosene heaters are prohibited at farm labor camps in New York State by an amendment to the State Sanitary Code. Approximately 35,000 migrants who work in more than 1,000 farm labor camps in the State each year will be affected.

Applicants for permits to operate camps will have to apply at least 30 days prior to the first day of opera-

tion, rather than 15 days as at present, according to another amendment.

Other amendments require hot and cold water at all bathing facilities of camps having a capacity of more than 25 people; heating facilities at camps occupied between October 1 and May 1; fire-resistant construction of new dwelling units housing 3 or more families or 15 or more persons; a minimum sleeping area of 40 square feet per person; and screens on all windows and exterior openings of living quarters.

Some of these changes are effective in 1959, others not until 1962.

« »

In Columbus, Ohio, the editors of the Ohio State Department of Health's monthly magazine left the beaten trail in September 1957 to produce an issue composed entirely of letters of inquiry from the public and answers to these letters by members of the health department's staff.

« »

With the aid of Hill-Burton funds, some States are allocating 36 percent of all new beds to chronic facilities, including nursing homes.

« »

Getting On—Safely, a recent 12-page publication of the National Safety Council, emphasizes special environmental aids and personal practices which can be used to prevent those types of accidents to which persons in the over-65 year age bracket are particularly susceptible.

The pamphlet is directed to the older person. A separate insert sheet, When An Elderly Person Lives With You, offers suggestions

to the younger adult who has the responsibility for the care of an elderly person.

Single sample copies are available, without charge, from the National Safety Council.

« »

Permits from the New York Department of Public Works are now required for industries that discharge industrial wastes into sewers which lead to sewage disposal or pollution control plants. Alcohols, antibiotics, arsenic, iodine, copper and copper salts, fluorine, formaldehydes, mercury, silver and silver compounds, zinc compounds, and such agents as nitrates and sulphides may be discharged into the sewer system only when diluted by other sewage to meet set standards. Eventually, fees will be charged for treatment of commercial wastes.

« »

Pamphlets entitled "Problems in Intercultural Health Programs," by George M. Foster, "Social Status and Public Health," by Ozzie G. Simmons, and "Effects of Social and Cultural Systems in Reactions to Stress," by William Caudill, were published by the Social Science Research Council, New York, N. Y., during the spring of 1958.

The Committee on Preventive Medicine and Social Science Research, appointed by the council, commissioned the publication of these pamphlets. Harold F. Dorn and H. van Zile Hyde of the Public Health Service were members of the committee.

« »

Aruba, a Caribbean island, has installed a \$10 million steam distillation plant to derive fresh water from the sea. The plant extracts 2,700,000 gallons daily at a cost of about \$1.50 per 1,000 gallons. (Domestic water usually costs 10 to 25 cents per 1,000 gallons.)

« »

"Water Fluoridation: Facts Not Myths" and "Cell Examination—New Hope In Cancer," Public Affairs Pamphlets Nos. 251 and 252, have been published by the Public Affairs Committee in New York City.

1958 INDEX

Public Health Reports

Volume 73, January–December

and

Public Health Monographs

Numbers 51–55

THIS INDEX to *Public Health Reports* and Public Health Monographs is divided into a subject index and an author index.

The subject index carries one or more entries for each item published. In addition to the subject headings, categorical headings include ANNOUNCEMENTS (ORGANIZATIONS, PERSONNEL, and SCHOOLS), CONFERENCE REPORTS, DEATHS, FILMS AND FILMOGRAPHS, FRONTISPICES, LEGAL NOTES, MONOGRAPHS, PUBLICATIONS, and TRAINING COURSES.

Public Health Monographs published concurrently with *Public Health Reports* in 1958 are listed in numerical order under the category heading MONOGRAPHS. The monograph summaries appearing in the journal are indexed under appropriate subject headings.

One asterisk before the page number indicates an original, signed article. The sign of two asterisks, used only in the author index, indicates a monograph. Entries without any symbol may refer to summaries or briefs of papers presented at conferences, narrative conference reports, statements or reports of committees, short reports without authors, or similar items.

Illustrative material on the inside of the front cover of each issue is indexed by month under the heading FRONTISPICES. It is recommended that the covers be included in a bound volume.

An annual list of Public Health Service publications may be obtained from the Public Inquiries Branch, Office of Information.

ECHOES from Public Health Reports

TULARÆMIA Francis 1921.¹

I. THE OCCURRENCE OF TULARÆMIA IN NATURE AS A DISEASE OF MAN.

By EDWARD FRANCIS, Surgeon, United States Public Health Service.

Tularæmia is a specific infectious disease due to *Bacterium tularensis* and is transmitted from rodents to man by the bite of an infected blood-sucking insect or by the handling and dissection of infected rodents by market men² or laboratory workers.³

As observed in Utah in the months of June, July, and August, the disease is initiated by the bite of an insect, most probably the blood-sucking horsefly, *Chrysops discalis*, which previously has bitten a jack rabbit infected with *Bacterium tularensis*. Following the fly bite on some exposed surface of the body (neck, face, hands, or legs) onset is sudden, with pains and fever; the patient is prostrated, is confined to bed; the lymph glands which drain the bite become tender, inflamed, and swollen, and commonly require incision. The fever is of a septic type, lasts for about six weeks, and convalescence is slow.

Probably two dozen cases occurred in Utah each of the years 1917, 1918, 1919, and 1920, but only one to have terminated fatally. The chief interest in tularæmia is its communicability which accounts for its being taken the far more seriously than the three months' fever. Tularæmia

PUBLICATIONS—Continued

Register of air pollution analysis as of January 1, 1956 (PHS Pub. No. 610)-----	1053
Rehabilitation of deaf-blind persons. A manual for professional workers (Industrial Home for the Blind)-----	860, 956
Relationship of marital status to hospital utilization and of insurance ownership to methods of paying for hospital care, year ending September 1956 (SSA Research and Statistics Note No. 25)-----	959
Reported tuberculosis data, calendar year 1955 (PHS Pub. No. 560)-----	191
Research and education in rheumatic diseases. Transactions of the second national conference (Arthritis and Rheumatism Foundation and the National Institute of Arthritis and Metabolic Diseases of the Public Health Service)-----	763
Research attack against cerebral palsy (PHS Pub. No. 552)-----	865
Research grants and awards, National Institutes of Health, 1957 (PHS Pub. No. 571)-----	380
Research publications of the National Heart Institute, January 1953-June 1958 (PHS Pub., unnumbered)-----	957
Review of mental health in industry (PHS Pub., unnumbered)-----	24
School health services. A selective review of evaluative studies (Children's Bureau Pub. No. 362)-----	956
Selected materials on staphylococcal disease (PHS Pub. No. 627)-----	1145
Sewage and water works construction, 1957 (PHS Pub. No. 608)-----	958
Simple goiter (PHS Pub. No. 100; Health Information Series No. 56, revised 1957)-----	474
Socioeconomic characteristics of persons who married between January 1947 and June 1954; United States (Vital Statistics—Special Reports; Selected Studies; vol. 45, No. 12, Sept. 9, 1957)-----	192
Sources of morbidity data, listing number 5, 1957 (PHS Pub. No. 565)-----	380
State occupational health programs (PHS Pub. No. 605)-----	957
State personnel in official and voluntary agencies concerned with agricultural migrants (PHS Pub., unnumbered)-----	763
Statistical summary of sewage works in the United States (PHS Pub. No. 609)-----	1145
Strike back at stroke (PHS Pub. No. 596)-----	764
Summary of health and vital statistics (PHS Pub. No. 600)-----	865
Survey of compounds which have been tested for carcinogenic activity, supplement 1 (PHS Pub. No. 149)-----	380
Taking care of diabetes (PHS Pub. No. 567)-----	762

PUBLICATIONS—Continued

Toward a healthier world. Your career in sanitary engineering (PHS Pub. No. 579)-----	380
Trachoma manual and atlas (PHS Pub. No. 541)-----	865
Training program of the National Institute of Mental Health, 1947-1957 (PHS Pub. No. 603)-----	957
Tuberculosis beds in hospitals and sanatoria, May 1, 1957 (PHS Pub. No. 518)-----	764
20th anniversary of the National Cancer Institute. Commemorative symposium (Journal of the National Cancer Institute, vol. 19, August 1957)-----	82
Uniform definitions of home accidents (PHS Pub. No. 577)-----	762
Urban fringe sanitation. A selected bibliography (PHS Pub. No. 583)-----	474
Using your community's health resources (Dept. Agriculture Rural Research Leaflet No. 5)-----	1145
VD fact sheet, 1957 (PHS Pub. No. 341, revised 1958)-----	959
Vending of food and beverages (PHS Pub. No. 546)-----	764
Vital statistics of the United States, 1956. Vol. II. Mortality data (NOVS Pub.)-----	958

QUARANTINE

measures against entry of yellow fever into United States, PHS-----	*1101

TRAINING COURSES

air pollution, Massachusetts Institute of Technology.....	521
air pollution, Universities of North Carolina and Minnesota Schools of Public Health.....	353
air pollution, University of California School of Public Health and College of Engineering.....	260
environmental engineering, Rensselaer Polytechnic Institute.....	448
environmental health, CDC.....	948
environmental health, specialized, RATSEC.....	1112
epidemiology and control of foodborne diseases, CDC.....	301
epidemiology for nurses, CDC.....	21
insect and rodent control, CDC.....	810
laboratory methods in diagnosis of tuberculosis, CDC.....	626
laboratory refresher, CDC, 1958-59.....	558
light and vision, University of Michigan School of Public Health.....	260
nuclear energy, institutes for engineering educators.....	444
nuclear energy, sanitary engineering aspects, RATSEC.....	970
perinatal casualties, University of Michigan School of Public Health.....	850
premature infants, New York State Department of Health and U. S. Children's Bureau.....	614

TRAINING COURSES—Continued

public health statistics, summer courses, University of Michigan School of Public Health.....	260
radiological health, RATSEC and University of Pittsburgh Graduate School of Public Health.....	740
radiological health, University of Michigan School of Public Health.....	524
radiological health, University of Minnesota School of Public Health.....	524
sanitary engineering graduate program, University of North Carolina School of Public Health.....	260
syphilis serology, VDRL.....	761

TRANSPORTATION

hazards to health and safety.....	*663
-----------------------------------	------

TUBERCULOSIS

ambulatory home care in low-budget countries.....	1137
casefinding in schools, recommendations.....	901
in cattle, casefinding and eradication in border States.....	1137
in children, isoniazid treatment.....	1137
mass surveys for, controlled evaluation of.....	*867
revised regulations for immigrants with.....	478
status, 1958, conference report.....	1015
treatment in general hospitals.....	*950
X-ray casefinding, PIIS statement.....	83

TYPHOID FEVER

carrier state, efficacy of chloramphenicol in preventing.....	*1039
---	-------

TYPHUS, MURINE

changing picture of.....	379
recurrence after eradication of rats and fleas.....	*469

URBANIZATION

problems solved by health department, Wichita, Kans.....	1029
public health implications of urban growth, conference report.....	795

VACCINES AND VACCINATIONS

Asian influenza vaccine, history and evaluation.....	*129
DTP vaccines, neonatal response to.....	*511
influenza, vaccine studies by Commission of Influenza.....	*133
influenza vaccines, 1919.....	132
poliomyelitis, fourth injection recommended in Mexico.....	1138
poliomyelitis incidence in Idaho after use of live virus vaccine.....	*637
poliomyelitis vaccination campaign, Bucks County, Pa.....	522
poliomyelitis vaccination campaign, Salt Lake City, Utah.....	*520

VENDING MACHINES

copper poisoning caused by carbonated beverages from.....	*910
recommended ordinance and code for food vending machines.....	*903

VENEREAL DISEASES

<i>see also</i> name of disease	
casefinding, New Mexico.....	1135
control intensified in Mexico.....	1134
control progress report, United States.....	1135
